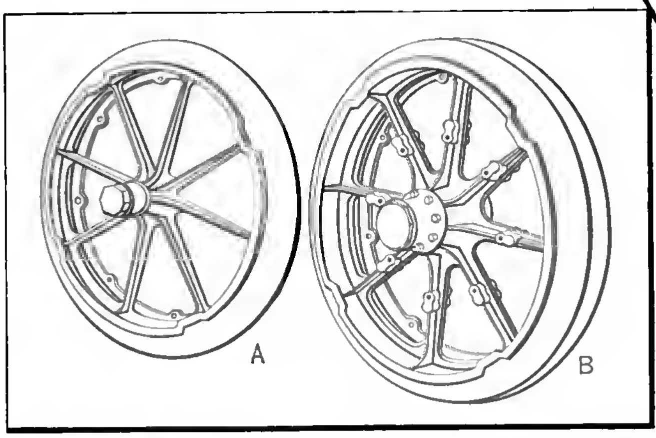
On the other side of the central zero the scale shows the retardation, as produced by the effect of the brakes, or when the car is coasting to a stop. Secondary scales beneath show upward and downward gradients in fractional form; the readings on these are correct only when the car is at a standstill or moving at constant speed. The instrument singles out and indicates only the acceleration produced by the motive power of the car; if the motor is powerful enough to give an acceleration of 2.2 feet per second per second on level ground, the instrument will still read 2.2 whether the start is made up hill or down hill. The same applies to the deceleration due to brake action.

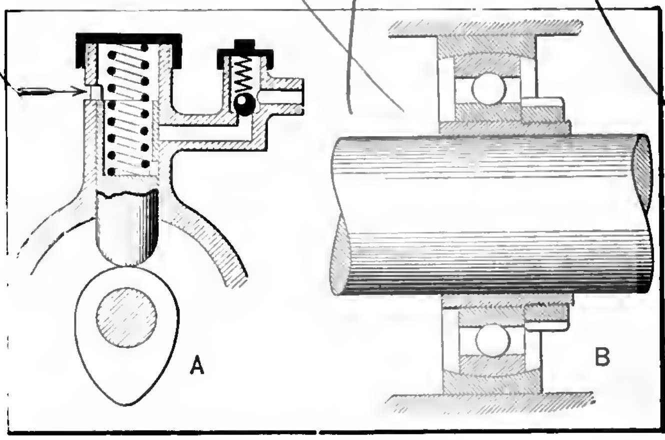
The principle of operation is that of inertia; inside the instrument there is a horizontal copper disc with an eccentric center of gravity, controlled by a light spring similar to the hairspring of a watch, and damped magnetically.

Wolseley-Siddeley Air Pump—This account of the pump fitted to maintain air pressure on the gasoline tank of the 20-28-horsepower Wolseley-Siddeley car is one of the novelties culled from the January 22 issue of the *Automotor Journal*.

A hollow plunger, with a key to prevent twisting and a spring to give return motion, is operated by a cam on the camshaft. On the upward movement of the plunger, the air contained in the upper enclosed chamber is compressed until the highest position of the plunger is reached; a small delivery port in the plunger then registers with a port in the cylinder, and the pressure is released into the pipe communicating with the tank. A ball check



Cast steel wheels used by the London General Omnibus Company, now regular equipment on vehicles plying in the English metropolis. A front, B rear wheel.



A shows diagrammatically the air pump used to maintain gasoline pressure on the Wolseley-Siddeley cars; B is the Stichel spherical-seated ball bearing.

valve assists in retaining the air thus entrapped. Owing to the proportion of clearance above the plunger, the air cannot be delivered at a pressure of more than 4 pounds to the square inch.

The spring returns the plunger, setting up a slight vacuum. As soon as the intake port is uncovered, the chamber is again filled at atmospheric pressure, and the compression is repeated. All the objections to the exhaust-pressure arrangement seem to be overcome by this pump. There can be no water introduced into the gasoline, no failure of pressure when the engine is running light, no sticking of the valve from gummed lubricating oil deposits. Of course, no safety valve is required.

Bingham Piston-Valve System—This ingenious valve motion, which was applied to a Bentall chassis on exhibition at the Olympia show in London, is described in the January 22 issue of the *Automotor Journal*.

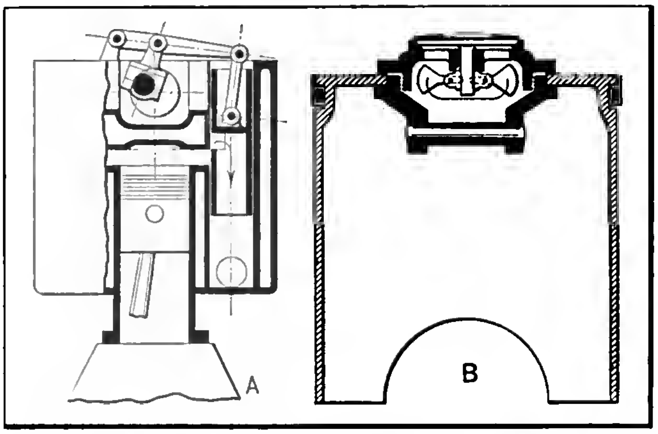
The overhead shaft is revolved at one-quarter the speed of the crankshaft, as the rectangular ports in the valve piston register with the cylinder port on both the up and down stroke of the valve. The very slow "valve speed" thus obtainable, together with the comparatively small diameter of the valves themselves, are points which should both tend toward long life. It should be noticed that during the power stroke the valves are not in lateral balance, the valve surface subjected to the explosion pressure being an area equal to that of the cylinder port; as, however, the valves are very long, the thrust from the explosion is distributed over a considerable surface.

One objection to the system is the five pin joints necessary to drive each valve. The two at the ends of the valve connecting rod are lightly loaded and have but a slight angular motion; the other three have little more movement, but approximately three times the load. There are several points of excellence—slow "valve speed," silent driving gear, probable immunity from leakage owing to small valve diameter, and considerable port area.

Daimler Spring Shackle—In the January 22 issue of the *Automotor Journal*, in a contest describing novelties seen at the Olympia show, one of the prizes is given to a description of the front spring shackle of the new Daimler cars.

When one front wheel of a car has to mount a considerable obstacle, in order to allow for the deflection of the spring on that side, the springs on both sides must necessarily twist. The ordinary spring shackles allow only for an equal spring deflection on both sides. For the twisting strain so often sustained the ordinary laminated spring is entirely unsuited, and this strain is the cause of much of the wear on the shackles and their pins.

The Daimler spring shackles at the rear ends of the front springs are designed so that they can swing laterally from pins arranged lengthwise of the car, which at the same time give the backward and forward play necessitated by the compression of the spring. As shown by the drawing, when one end of the axle is considerably raised, both shackles swing until their pins are approximately parallel to the axle. A slight spring torsion must still take place, however, as the unshackled front end of the spring will not allow any sidewise swinging. At the same time there is no additional complication.



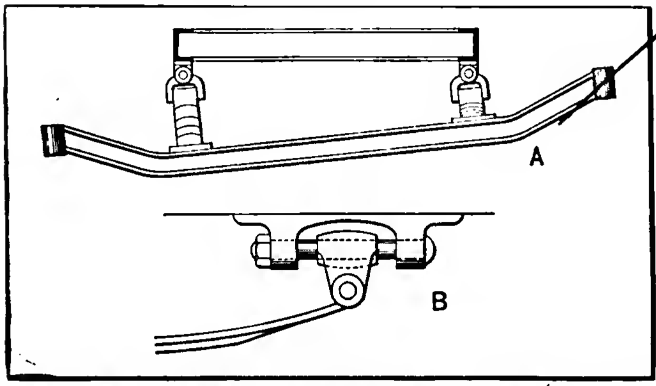
A—The Bingham piston valve system used on the Bentall cars; B—Inlet valve located in cylinder head, on the seven-cylinder Gnome aeronautic motor.

Stichel Ball Bearing—German patent No. 216,502, granted to Otto Stichel, of Leipzig, covers a ball bearing mounted in a spherical seat. The construction of the bearing permits a lengthwise movement of the shaft, such as may naturally occur through changes in temperature, and also a change in direction of the axis, a condition especially to be provided for in automobiles. Thus is prevented any pinching of the balls, which is likely to result in breakage. The outer ball race is spherical on its outer surface, and has a special ring with a spherical inner surface to receive it. The outer surface of this ring is cylindrical, and is mounted in the usual manner, with a slight allowance for endwise motion.

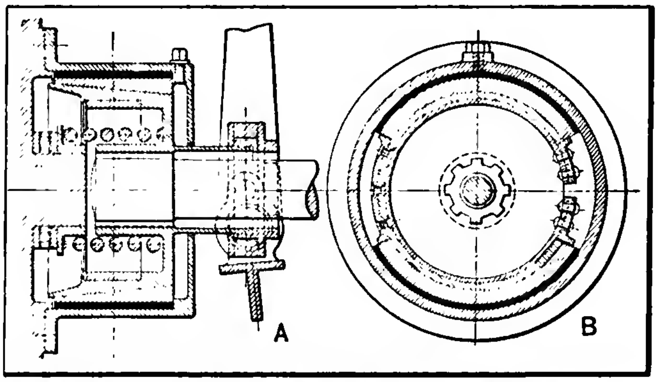
Expanding Band Clutch—The clutch illustrated herewith is used by several makes of French commercial cars, and has been found very satisfactory. It consists of a cast-iron cylinder, bolted to the flywheel, inside of which a brake band is caused to expand by a sliding cone.

There are two brake shoes, faced with a suitable friction material, with their inner faces of a conical shape. They are supported by a conical-faced drum keyed to the clutch shaft, and are held from revolving with respect to the drum by angle pieces riveted to the face of the latter. Inside of the drum is a spring-steel band, the ends of which project through a split in the drum and bear against the sides of the brake shoes. Thus each shoe is supported on one side by a stop on the face of the drum, and on the other by an end of the steel band. The conical drum is pressed out by a coil spring, in its turn thrusting the brake shoes apart and into engagement with the inner surface of the cylindrical drum bolted to the flywheel. To release, the cone is pushed in, and the spring band draws the brake shoes together and out of engagement.

Much smoothness of engagement, besides a quick and positive disengagement, are claimed for this form of clutch. In addition it is simple, not likely to get out of order, cheaply built and has little inertia to cause spinning in gear-changing.



Two views of the Daimler shackle used on the rear end of the front spring. A shows the displacement of the axle, and B the shackle itself.



Expanding band clutch used successfully on several French commercial cars; A shows the longitudinal, and B the lateral section of the clutch.

RECENT CLUB ACTIVITIES

BUCKEYE CAPITAL'S CLUB TO BE REORGANIZED

COLUMBUS, O., Feb. 14—A complete reorganization of the Columbus Automobile Club will be made at a special meeting to be held in a few weeks. This was decided on recently when a committee was named to draft a new constitution and by-laws which will be presented to the membership. The plan is modeled after that in vogue in Cincinnati and Cleveland, which has proved a success.

The feature of the plan is a board of governors, which will meet weekly with the salaried secretary. All matters of moment will come before the board of governors and this will take the work and responsibility off the officers, as has been the case in the past. A campaign for membership is being started and it is expected to double the number of members.

A. C. A. ACTIVITY OF A TECHNICAL CHARACTER

A. L. McMurtry, chairman of the technical committee of the A. C. A., is kept very busy these days making tests and investigations of a character which should prove of the greatest possible interest to the automobile industry at large as well as to the members of the club. The facilities afforded for original research at the club are such that the results should be reliable, and, in the hands of McMurtry, exactness is to be expected. The club dynamometer is receiving a quota of attention, and it may be that something will be made of it in the long run. It is now proposed to eliminate errors by driving from the dynamometer motor through a device which will be fastened to the wheel of the automobile. This will, to some extent, lessen the present slight errors due to tire slippages.

IOWA CITY GETS AUTO CLUB

Articles of incorporation of the Iowa City, Iowa, Automobile Club have been filed with the county recorder. This club is not born for pecuniary purposes, and has no capital stock. The object of the organization is to battle for good roads and to secure if possible other much needed reforms.

The incorporators and directors are: F. C. Carson, F. X. Freyder, O. H. Carpenter, James W. Dvorsky, Ed. B. Wilson, John McCollister and Will Carson. The charter officers are: President, Frank C. Carson; Vice-President, F. Freyder; Secretary, O. H. Carpenter; Treasurer, James W. Dvorsky.

OHIO'S GROWING ROLL OF COUNTRY CLUBS

CANTON, O., Feb 14—At a meeting of autoists of Stark County, held at this city recently, the organization of the Automobile Club of Star County was effected. The club starts with a membership of 126. A fee of $5 is charged, which entitles the members to membership in the A. A. A. The club will hold monthly meetings. Officers were elected as follows: J. H. Kenny, president; Charles Steese, Jr., Massillon, vice-president; W. A. Hoberdier, secretary-treasurer. The board of governors consists of Edward E. Bender, J. R. Dangler, John Sherer, W. L. Stolzbacher and J. G. Best.

ANNUAL ELECTION OF CENTURY MOTOR CLUB

The Century Motor Club of Philadelphia, at its annual meeting, elected the following officers: J. Fred Hartman, president; Frank R. Isaac, vice-president; C. D. Holden, secretary; F. R. Davis, treasurer, and the following board of directors: Edwin M. Abbott, J. Howard Clarke, Edward H. Ervin, H. G. Evans, Henry Goldthrop, Ralph Humphreys, Lucien V. Leach, Dr. C. F. Rau, Dr. Clayton S. Schwenk, C. B. Sears and R. N. Storey. Edwin M. Abbott was elected counsel for the club.

ANOTHER COUNTY IN WISCONSIN HEARD FROM

The Rusk County Automobile Club has been organized with headquarters at Ladysmith, Wis., and will doubtless affiliate with the Wisconsin State Automobile Association. E. M. Worden, of Ladysmith, was elected president and the other officers are: T. M. Thomas, secretary; H. W. True, treasurer.

SHOW BREVITIES

INDIVIDUAL SHOWS IN INDIANAPOLIS

INDIANAPOLIS, Feb. 14—The annual automobile show in this city will be held during the week of March 28, and as usual will be under the auspices of the Indianapolis Automobile Trade Association, which now has forty-nine members, embracing dealers and manufacturers, both of cars and accessories. This year's show will be of more importance than usual, owing to the general enthusiasm that is being shown in the plans.

Each dealer and manufacturer will exhibit in his own establishment. This will be necessary from the fact that the only building that would be evailable for a show all under one roof, is located at the State Fair grounds, about four miles from the city and regarded as too inaccessible to the public. To make up for the fact that the show will not be under one roof, the association arranged an elaborate program of outdoor events.

The first of these will be a magnificent floral parade on Wednesday afternoon. On Thursday afternoon there will be a program of speed trials and novelty events at the Indianapolis motor speedway, taking the place of similar events that have been held on the North Capital avenue boulevard during show week in previous years. Another parade will be given Friday, exclusively for commercial cars, of which there are about 150 in the city.

Officers of the I. A. T. A. are: President, Fred I. Willis, of the Hearsey-Willis Company; secretary, Frank B. Willis, of the Willis-Holcomb Company, and treasurer, Frank L. Moore, of the Fisher Automobile Company.

DENVER ENTHUSIASTIC OVER SHOW PROSPECTS

DENVER, Feb. 11—The preparations for the second annual automobile show, to be held in the Auditorium, February 23 to 26, are almost complete, and are most encouraging to the members of the promoting body, the Denver Motor Club. The show will undoubtedly rank high among those held west of Chicago. The club has had an artist busy for several days on the color schemes and decorative effects, so that the decorators have a plan to work on. All exhibits will be decorated uniformly.

With the exception of a few small boxes the floor space has already been disposed of. The list includes dealers handling 37 makes of automobiles, besides a number of motorcycles and a goodly array of accessories.

PROSPERITY SHOVES OMAHA SHOW TO FRONT

Everything points to the show this year being a tremendous success. Not only is the entire main floor filled up, but the management has been compelled to open up the basement, and the space there has also been contracted for.

LAW AND THE AUTOMOBILE

FEW CHANGES DESIRED IN BAY STATE LAWS

BOSTON, Feb. 14—Little inclination on the part of automobilists or "antis" to tinker with the Massachusetts automobile law has yet appeared in the Legislature. Apparently all hands prefer to wait until the law, which became fully effective the first of the year has been given a test before suggesting amendments or changes. But whatever the cause may be there have been fewer bills filed at the State House relating to the operation of automobiles than in any session of the Legislature for a long time. There are some important measures proposed concerning highways and therefore indirectly affecting the motorists, but of strictly automobile bills there are only three or four.

Two of these are the so-called "light" bills, a piece of legislation that has been proposed in recent years as often as the Legislature has met, and has been as regularly rejected on account largely of the rural influence, which objects strongly to protecting itself by carrying a light on horse-drawn vehicles at night. Both the bills propose that all horse-drawn vehicles using the highways from a half-hour after sunset until a half-hour before sunrise shall carry a light or lights, the size and location of which are left to the determination of the Highway Commission. These bills have been referred as usual to the committee on roads and bridges.

The bedlam created especially in the cities, by that part of the new law requiring the sounding of a warning signal by an automobile operator when approaching a corner, curve, intersecting way or a pedestrian not on the sidewalk has got on the nerves of some people, and a bill has been filed designed to diminish it. This bill would limit warning devices to the ordinary horns and bells and prohibit the harsh-toned instruments of torture that have become common of late and which, being easily sounded, are set off in complete compliance with the law. It may be also that some effort will be made to modify the law so that incessant sounding of horns will be unnecessary.

The Highway Commission this year makes no recommendations whatever for changes in the automobile law. It makes some important suggestions, however, in regard to highways. One of these is that in the process of elimination of grade crossings with railroads which is going on all over the State, more attention should be given the rights of automobilists and other users of the highways. It recommends that in cases where the railroad is carried over the highway there shall be a clear view ahead of at least 150 to 200 feet and that on curves there shall be a clear view of the roadway for at least 150 feet. In some cases where crossings have been abolished the conditions for users of the highway have been made more dangerous than before, and the board cites instances where underpasses are paproached at sharp angles or where the bridge is too narrow, in some cases vehicles being obliged to approach a blind turn and swing onto electric car tracks in order to go under the railroad. Another important suggestion of the Highway Commission is for a broader administration of the highways by their division into main, secondary and local routes. Such a system would lend itself to better and more economical administration.

VERY STIFF SENTENCE FOR CAR STEALER

BUFFALO, Feb. 14.—Nine years and eight months imprisonment at hard labor was the sentence passed upon an inveterate motor car thief by Justice Truman G. White in Part III of the Supreme Court to-day. The prisoner earning this the stiffest sentence that has been dealt out for grand larceny in Buffalo in a long time was Ed. Houck. But for the fact that the law prohibits a sentence under which prisoners are liable to leave prison in the cold months, Justice White would have given Houck the limit, 10 years.

Houck was convicted of stealing an automobile the first time in 1906. He was given a suspended sentence for this. The next year he stole another machine, and was sentenced to a year in the Elmira Reformatory. When he emerged in 1908 on parole, he stole another machine, and was given another year for violating his parole. He had not been out a month after serving time for the theft of the third automobile before he stole his fourth.

ROAD BUILDING NEWS

GOOD ROADS PLENTIFUL IN THE BLUE GRASS COUNTRY

LOUISVILLE, KY., Feb. 14—In the mountain sections of Kentucky, Tennessee and Virginia, where formerly the roads were practically nothing more than creek beds, available in dry weather and impassable in the rainy season, it is interesting to note the development with reference to improved highways. Appreciation of good roads by the people of the Cumberland Mountains has been due in a large measure to the construction of the military road through Cumberland Gap. This road was built by United States Government engineers as an object lesson, for the purpose of showing that road building is possible in any section. It has been in use for more than a year and is as smooth as asphalt.

The road was constructed along the line of the old Wilderness road, through which pioneers first entered eastern and interior Kentucky. It is the great traveled highway from Virginia to Kentucky and Tennessee. Since its completion, the Cumberland Gap Military road has been used continuously for automobiles, log wagons and all sorts of vehicles.

Automobilists passing through this part of the country will be most richly repaid. In its sublimity the scenery cannot be equalled anywhere and the environments are full of historic interest. If the shade of Daniel Boone could see the excellent highway that has supplanted his old trail he, too, would be convinced that good road ideas have spread marvelously since his day.

Since the advent of the automobile, road development throughout the entire South has been more pronounced than any previous period. Miles and miles of roadway, as level as a well-kept boulevard, can be found in the Blue Grass section of Kentucky. This part of the State is famous for its good roads, which are among the finest in the country.

In Kentucky there has been considerable speculation in respect to the relative severity of the automobile and the horse-drawn vehicle on macadam highways. Numerous tests have been made practically all of which have developed the fact that an automobile is less destructive than horse-drawn vehicles.

The Louisville Automobile Dealers' Association deserves the good will of every automobilist who has used the roads in the vicinity of Louisville. It has been instrumental in the posting of the roads throughout this section of the State. The work has been in progress many months, and the various signs indicate all bad places, the speed limits as well as the distance to the various points about the city. As a result of the efforts of the Louisville Automobile Club and the Louisville Dealers' Association the roads in the vicinity of Louisville are in an excellent state of repair. This is a condition much to be desired, and one that other parts of the country might well try to match.

HERRESHOFF

HERRESHOFF, in the car for 1910, is offering a car which especially appeals to purchasers who put quality ahead of price, and, in view of the mechanical perfections of the power plant, it is made the feature of this article. This plant is of the unit type, with the magneto on the left and the carbureter on the right side.

SELF-CONTAINED POWER PLANT REPRESENTS A UNIT

The motor is of a four-cycle, four-cylinder, water-cooled type, with cylinders cast in pairs, with integral water jackets. The cylinder bore is 3 3-8 inches, and the stroke is 3 3-4 inches. The inlet and exhaust valves are of large diameter, interchangeable, and are located on one side. This construction operates to reduce the loss of heat in the water jackets and to conserve the power, since the incoming gas helps to cool the exhaust chamber.

The valves are operated by very hard steel cams, on one camshaft, which is mounted on imported ball bearings. The inlet and exhaust manifolds are large and have no elbows or corners for the collection of gas. The former is designed to allow the passage of gas to the cylinders with the least amount of friction and the latter to relieve the cylinders of the burnt gases with the least possible back pressure—thus preventing overheating and a consequent loss of power.

The crankshaft runs on three imported ball bearings; it is a drop forging of the best grade of steel for the service it performs, and ground to exact size. In order that it will run without vibration, the shaft is "balanced" as a unit and with flywheel assembled.

The connecting rods are of drop-forged steel of I-section, designed to withstand the heavy compressive stress they necessarily have to carry. The connecting rod caps are doweled and held in place with chrome nickel-steel bolts. The bearings on the crankshaft are of ample proportions and made of special grade of die-cast babbit. The upper ends of the connecting rods are securely clamped to hollow wrist-pins of special design, which have their bearings in the pistons. The latter are made of the very best grade of gray iron, and well ribbed to withstand the high pressure of the explosion. There are four eccentric piston rings, made of special cast iron and ground to size.

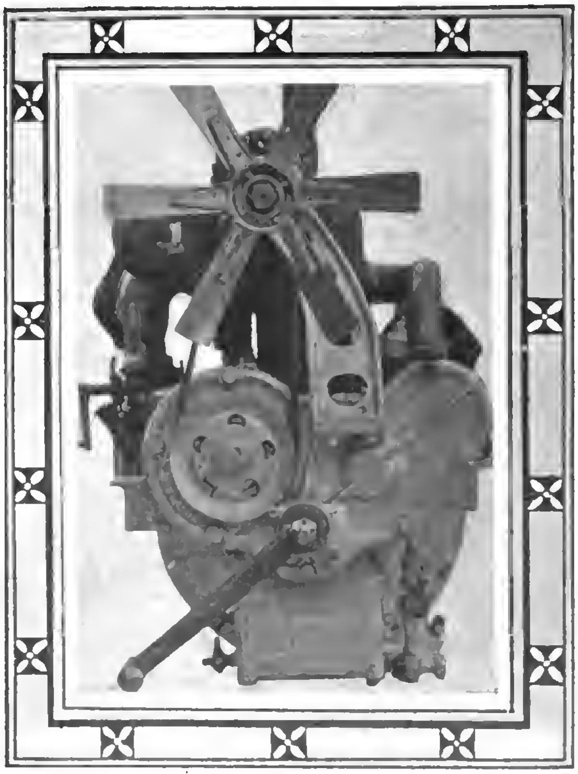


Fig. 1—Front end view of the motor, depicting the encased half-time gear system, air propeller and starting crank.

The carbureter is of the float-feed automatic type, the gasoline feed being regulated by a graduated needle valve. The gas is controlled by a hand lever on the steering wheel and by a foot acclerator. The gasoline tank is placed under the driver's seat, the gasoline being fed by gravity to the carbureter. On the runabout and tourabout types, an air pump is provided for pressure feed for use on hills.

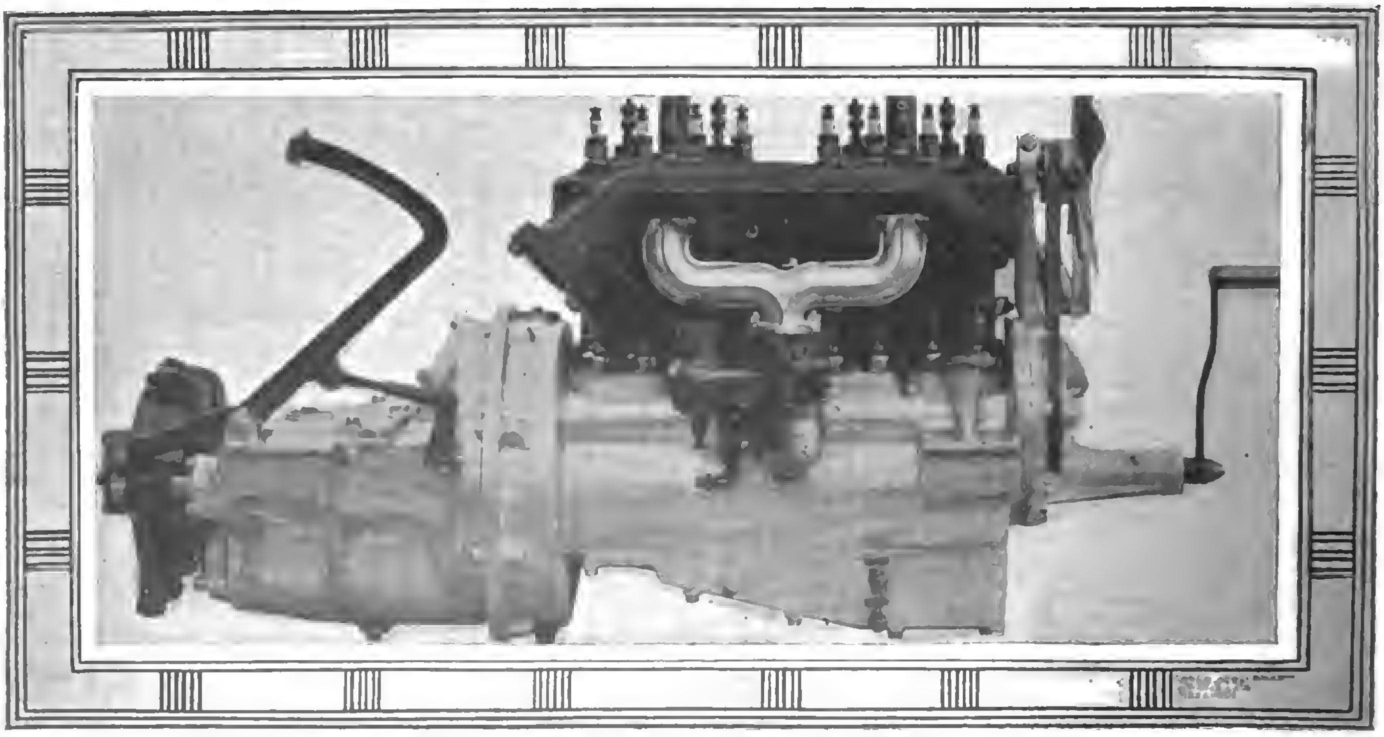

Fig. 2—Right side of the unit power plant, showing location of carbureter, contour of piping and compactness

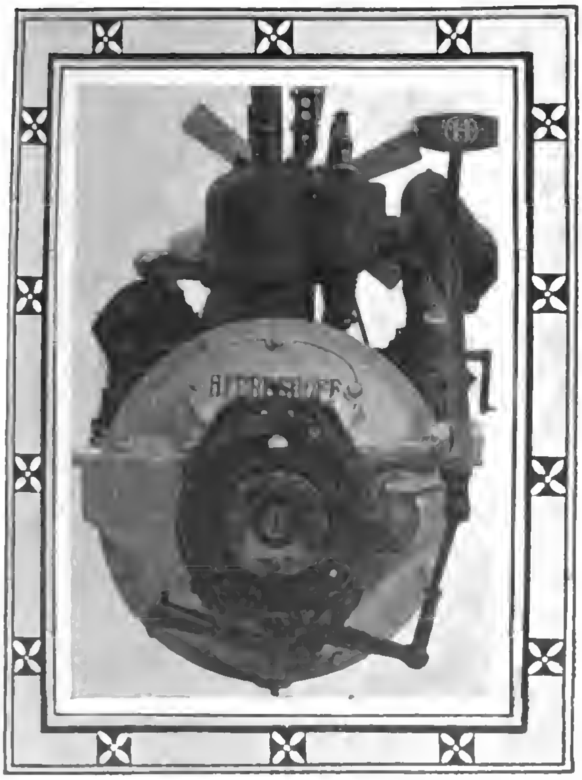

Fig. 3—Rear end view of the motor looking into the flywheel, showing details of the connections for the clutch

COOLING SYSTEM INCLUDES A VERTICAL TUBE RADIATOR

The vertical type radiator is of large capacity and of such shape and proportion as to give the car an imposing front. The drawn brass pipes, which carries the water to and from the cylinders are carefully proportioned, and of large capacity—thus facilitating the thermo circulation. The fan behind the radiator is mounted on ball bearings, and driven by a V-shaped belt from a pulley keyed to an extension of the camshaft.

Two of the best independent systems of ignition are provided—high-tension Bosch magneto, operated with a fixed spark; and a storage battery, four-unit coil and timer. These two systems are controlled by a switch in easy reach on the coil box, located on the dash.

The magneto is located on the left-hand side of the crankcase and is held in position by a clamped band. It is driven from the crankshaft gear through an idler gear. A flexible coupling is provided in its driving shaft, which shaft is mounted upon imported ball bearings. All high-tension cables are carried in insulated brackets so that short-circuits are practically impossible. The timer in connection with the storage battery circuit, runs on ball bearings, and is of approved design, and driven from the magneto driving shaft by spiral gears.

CONSTANT LUBRICATION BY POSITIVE FEED SYSTEM

The lubrication of the motor is by a constant feed system and operated by a self-contained gear pump. A reserve reservoir is located underneath the crankcase proper, from which the oil is pumped through a copper tube to the sight feed on the dash, from which it is fed by gravity into the two compartments of the crankcase, where a constant level is maintained. The lower tips of the connecting rod bolts dip into this oil and throw it to all parts within the case and pistons. A strainer is provided in the reserve reservoir so that foreign substances are not drawn into the system. The gear pump is driven by the same spiral gear which drives the timer.

Adequate lubrication is one of the most essential features of a successful car, since without it the most perfectly constructed mechanism will not give satisfactory service and will wear out quickly. Our oiling system is positive in its action, and can therefore be depended upon to keep in well-lubricated condition our carefully designed mechanisms. This system has been successfully used for years past on prominent makes of cars.

The Herreshoff Motor Car Company, Detroit, Mich., is the maker of this product and, contrary to the usual agency methods, the cars are handled direct from the plant. There are two models, one of which is a runabout, and the other, as a touring car, seats four.

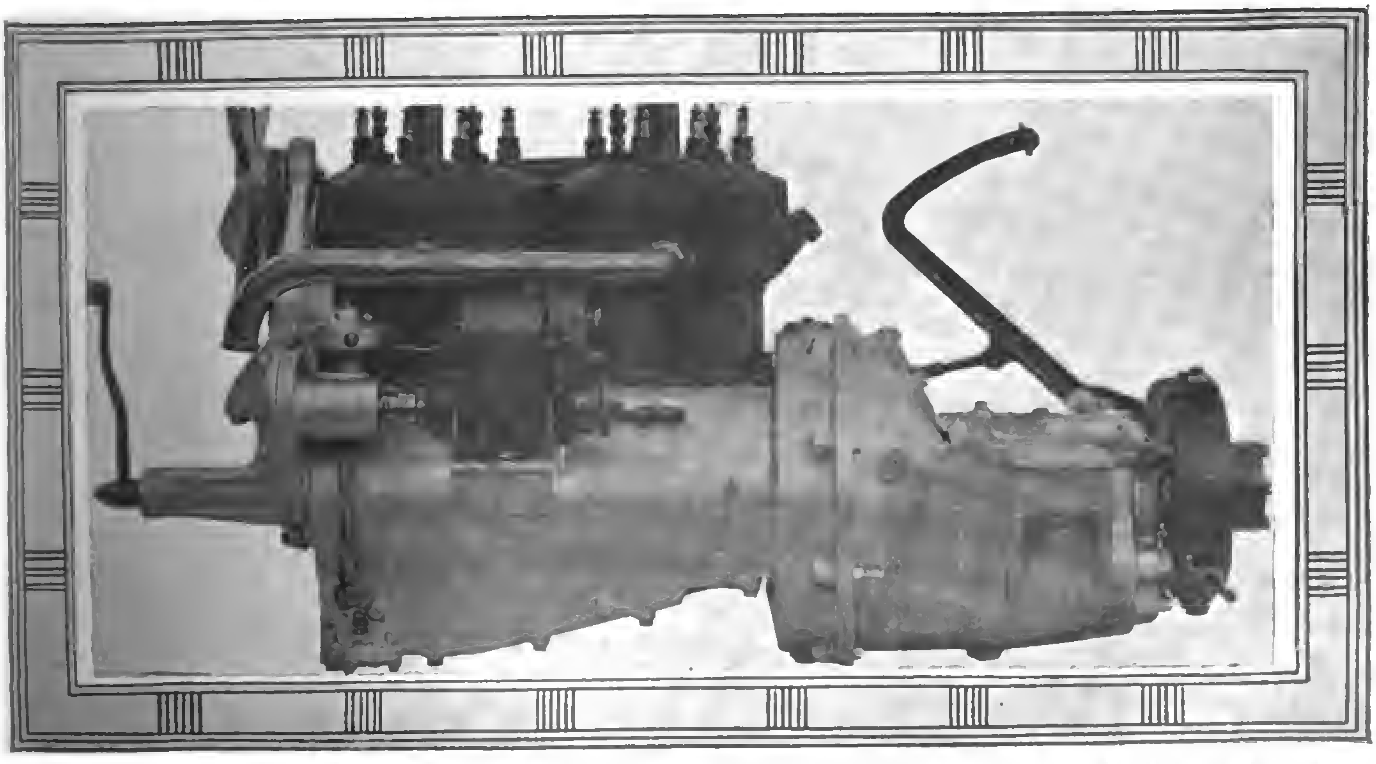

Fig. 4—Left side of the power plant, showing location of magneto, method of fastening and other mechanical features of note

DIFFICULTIES IN THE WAY OF STANDARDIZATION

THAT the automobile will ultimately be standardized is one of the things that is fast becoming too apparent to be disregarded, and this point is never so clearly brought out as when a "public letting" has to be struggled with. When some branch of the Government undertakes to purchase an automobile an elaborate contract is first drawn up, it being the handiwork of the office of the Corporation Counsel or other legal illuminaries with specific reference to a general specification of the automobile which is wanted. The lawyers seem to have very little trouble in drawing up the contract, but the mechanical experts fail utterly to describe a theoretical automobile which will come within many miles of what the bidders would have to offer, there being no definite relation of the several makes of automobiles to a theoretical standard (or standard arrived at by engineering bodies), so that all the legal phraseology which comes from the office of the Corporation Counsel, for illustration, is wasted in view of the absence of any language which will fairly describe an automobile in the abstract, with the understanding that the lowest competent bidder will truly deliver a satisfactory machine and with the further understanding that every maker will be equally and justly treated. A purchasing contract seems to be a most formidable document, and with the idea of showing something of this angle a blank form which emanated from the legal department of a city government is here given. The real question, however, remains unanswered, and it is believed that this question should be discussed at sufficient length to harmonize the details so that in the long run purchasers will be enabled to determine as to the real value of the respective automobiles if purchased under a contract such as this. The columns of THE AUTOMOBILE are open to pertinent discussion from any competent source.

CONTRACT AND SPECIFICATIONS

FOR FURNISHING AND DELIVERING ONE (1) AUTOMOBILE AND ACCESSORIES

Parties

This agreement entered into this..............................day of..................in the year nineteen hundred and.............., between .... of .... City.................County and State of.......................... to be known hereinafter as the "Purchaser," and.................. ....of..................City.................County and State of..............................to be known hereinafter as the Contractor.

Covenant

Witnesseth, the parties of these presents, each in consideration of the agreements on the part and behalf of the other herein contained, have agreed, and hereby agree, the party of the first part for himself and with successors, and the party of the second part for him (or them) self (or selves) and his (or their) executors and administrators, as follows:

(A) That wherever the term "purchaser" is used, or a pronoun instead, such term shall refer to and mean the party first above mentioned, and no other.

(B) That wherever the term "contractor" is used, or a pronoun instead, such term shall refer to and mean the party second above mentioned, and no other.

(C) Wherever the word "engineer" is used in these specifications, or in this contract, it refers to and designates Mr............ .... supervising engineer of the purchaser, acting either directly or through any assistant or inspector, duly appointed by the purchaser, or designated therefor by the supervising engineer of the purchaser, or through any such assistant, to receive, weigh, inventory, or inspect the automobile, in whole or in part, or the accessories thereunto belonging, or to be furnished, limited by the particular duties intrusted to him, or them.

(D) Wherever it is provided that anything is to be, or to be done, if or as, or when or where "approved," "required," "directed," "specified," "designated," or "deemed necessary," it shall be taken, unless otherwise expressed, to mean and intend, approve, required, directed, specified, designated, or deemed necessary, as the case may be, by the purchaser or the engineer of the purchaser.

(E) The contractor will provide, furnish and deliver to the purchaser, at his own cost and expense, at the time and place, and in the manner and under the conditions hereinafter specified, the automobile and accessories mentioned, and described in the specifications and schedule, and will accept as full compensation therefor the sum set opposite the respective articles or classes of articles in the specifications or schedule herein contained or hereto annexed, the said sum being the amount at which the contract therefor was awarded to the contractor at the letting thereof.

(F) This contract and specifications is the complete and final instrument embodying this entire transaction, superseding all previous written and oral discussions, agreements, or understandings in relation to this subject matter, subject to no changes, additions or subtractions whatsoever, excepting by virtue of a written supplementary contract, duly executed by the parties hereunto.

(G) The contractor will give his personal attention constantly to the faithful prosecution of the work; he will not assign, transfer, convey, sub-let, or otherwise dispose of this contract, or his right, title or interest in or to the same or any part thereof, without the previous consent in writing of the purchaser, endorsed hereon, and he will not assign, by power of attorney or otherwise, any of the moneys to become due, and payable under this contract, unless by such previous written consent, signified in like manner. If the contractor shall, without such previous written consent, assign, transfer, convey, sub-let, or otherwise dispose of this contract, or of his right, title or interest therein, or any of the moneys to become due under this contract, to any other person or other corporation, this contract may, at the option of the said purchaser, be revoked, annulled, and the purchaser shall thereupon be discharged from any and all liability and obligations growing out of the same to the contractor, and to his assignee or transferee, provided that nothing herein contained shall be construed to hinder, prevent or affect an assignment by the contractor for the benefit of his creditors, made pursuant to the statutes of the State of..........................; and no right under this contract, or to any money to become due hereunder, shall be asserted against the purchaser, in law or in equity, by reason of any so-called assignment of this contract, or any part thereof, or of any money to grow due hereurder, unless authorized as aforesaid, by the written consent of the said purchaser.

(H) The said automobile and accessories and each and every part thereof shall in all respects conform strictly with the herein-contained specifications, and schedules referred to, by the purchaser as a standard of quality, style, finish, or manufacture that will be required.

(I) The purchaser may appoint such engineer, inspector, or assistant as may be deemed proper to inspect the automobile or the accessories furnished and delivered under this contract, and such engineer, inspector, or assistants are authorized and empowered to reject and refuse any part, or the entire equipment, if any part thereof offered under or in fulfillment of this contract does not comply in kind, quality, or quantity, size or number, or weight, or in time or in place of delivery, with the said specifications.

(J) Any part or parts of the said automobile or accessories delivered or offered to be delivered under this agreement, which shall be rejected by the engineer, inspector, or assistant, as not conforming to the aforesaid specifications, shall be forthwith removed, and the part or parts which do so conform shall be furnished and delivered in the place thereof.

(K) The automobile and accessories provided for in this contract and set forth in these specifications must be delivered within .... (........) days, exclusive of Sundays and legal holidays, from the date of order.

(L) To prevent all disputes and litigations, the "purchaser" shall in all cases determine the amount or the quantity of the automobile and accessories to be paid for under this contract, and shall determine all questions in relation to said automobile and accessories, their quantity, delivery and condition, and he shall in all cases decide every question which may arise relative to the execution of this contract, on the part of the contractor, and his estimate and decision shall be final and conclusive and shall be a condition precedent to the recovery of any sum or sums of money by the contractor under this contract.

(M) If the contractor shall well and faithfully perform and fulfill this contract and keep every covenant on his part herein contained, the purchaser will then, but not before, pay to the contractor the sum of ....dollars ($..............), but no more.

(N) The contractor shall not be entitled to demand or receive payment for the said automobile and accessories, or any part thereof, or accept in the manner set forth in this agreement, nor until each and every one of the stipulations herein mentioned are complied with, and the engineer shall have given his certificate to that effect, provided that nothing herein be construed to affect the right hereby reserved by the purchaser to reject the whole or any part of the automobile, and accessories, delivered or offered for delivery, should the said certificate be found or known to be inconsistent with the terms of the agreement or otherwise improperly given.

(O) The contractor shall be responsible for any claim made against the purchaser for any infringement of patent right for the sale, supply or use of any patented articles, materials, or apparatus furnished or supplied under this contract, and that he shall save harmless and indemnify the purchaser for all costs, expenses and damages which the purchaser shall be obliged to pay by reason of any infringement of patent resulting from such sale, delivery, or use of said automobile and accessories, or any part thereof.

(P) If the contractor shall fail to furnish and deliver the automobile and accessories as herein agreed to be furnished and delivered, or any of them or any part of them, at the time or in any manner when or wherein they are agreed to be delivered, or if this contract shall be sublet or assigned by the contractor otherwise than as herein specified, the purchaser shall have the power to notify the contractor to discontinue all delivery, or any part thereof under this contract, by a written notice signed on behalf of said purchaser by himself or the engineer to be served upon the contractor either personally or by leaving the same at his residence or with his agent in charge of the work; and thereupon the contractor shall discontinue the delivery of said automobile and accessories or such part thereof as the purchaser may designate, and the purchaser shall thereupon have the power, in the manner described by law, to contract for the completion of the work, by contract or otherwise, as the purchaser may deem advisable, and charge the expense thereof to the contractor, and the expense so charged shall be deducted and paid by the purchaser out of the moneys that may then be due, or thereafter grow due, to the contractor under and by virtue of this agreement, and in case such expense shall exceed the sum which would have been payable under this contract, if the same had been completed by the contractor, then the contractor shall pay the amount of such excess to the purchaser or notice from the purchaser of the amount of such excess, and in case such expense shall be less than the sum which would have been payable under this contract, if the same had been completed by the contractor, then the contractor shall receive the difference, after deducting ten (10) dollars per day for each working day, between the contract date of delivery and the date of completion of the work.

(Q) The residence or place of business given in the bid or estimate upon which this contract is founded is hereby designated as the place where all notices, letters and other communications shall be served, mailed or delivered. Any notice, letter or other communication addressed to the contractor and delivered at the above named place, or deposited in a post-paid wrapper in any post office, shall be demed sufficient service notice thereof upon the contractor. The place named may be changed at any time by an instrument in writing, executed and acknowledged by the contractor, and delivered to the purchaser. Nothing herein contained shall be deemed to preclude or render inopsrative service of any notice, letter or other communication upon the contractor personally.

(R) The contractor may make delivery of the said automobile and accessories within........................... (................) days, Sundays and legal holidays excepted, and.................. .... (................) days, Sundays and legal holidays excepted, from the date of execution of this instrument by the parties hereunto.

(S) In case the contractor shall fail to complete the delivery of such automobile and accessories in accord with the specifications, and to the satisfaction of the purchaser, within the time aforesaid, the contractor shall and will pay the purchaser an amount equal to 1 per cent. of the contract price for each and every day the time consumed in said delivery may exceed the time hereinbefore allowed for the purpose, which said amount, in view of the difficulty of ascertaining the loss which the purchaser will suffer by reason of delay in the delivery of the said automobile and accessories, or any part thereof, is hereby agreed upon, fixed and determined by the said parties hereunto as the liquidated damages that the purchaser will suffer by reason of said delay and default, and not as a penalty, and the purchaser shall and may deduct and retain the amount of said liquidated damages out of the moneys which may be due or become due to the contractor under this agreement. Nothing herein contained shall be deemed to preclude or render inoperative the right of the purchaser as set forth in clause (P).

(T) The purchaser shall not be precluded or stopped by any return of certificate made or given by the engineer or assistants of the purchaser under any provisions of this agreement, from, at any time (either before or after the final completion and acceptance of the work and payment therefor, pursuant to any such return or certificate) showing the true and correct amount and charaoter of the work done and materials furnished by the contractor, or any other person under this agreemsnt, or from showing at any time that any such return or certificate is untrue and incorrect, or improperly made in any particular, or that the work and material, or any part thereof, does not in fact conform to the specifications; and the purchaser shall not be precluded and estopped, notwithstanding any such return or certificate and payment in accordance therewith, from demanding and recovering from the contraotor the refunding to the full amount of the contract price, less 1 per cent. of the contract price for each and every week the time consumed by the purchaser up to the day upon which notice is served upon the contractor that the said automobile and accessories, or any part thereof, do not conform to the specifications, and it is the purpose of the purchaser to surrender, the said automobile and accessories upon receipt from the contractor of the contract price, less deductions as herein set forth.

(U) The contractor shall not pay, directly or indirectly, to any agent, representative or employee of the purohaser any commission, or other compensation, upon any account whatsoever bearing upon this contract, and the purchaser shall not be precluded or estopped from demanding and recovering a sum equal to any such payment upon discovery of the fact, or deduoting the amount from the contract price before payment, if the information is obtained prior to the date of settlement.

(V) The contraotor shall stand for loss or damage due to or caused by fire or other source sustained by the said automobile and accessories, or any part thereof, prior to the date of acceptance of the automobile and accessories by the purchaser.

(W) The said automobile and accessories when delivered shall be in good running order, fully adjusted in all its parts and ready for service forthwith, including a full supply of lubricating oil, liquid fuel, and nseded supplies up to the limit of the storage capacity provided and specified.

(X) The contractor shall insure the said automobile and accessories against fire and accidental damage, and pay ths premium thereon, and the said insurance policies shall be assigned to the purchaser forthwith upon delivery and acceptance of the said automobile and accessories. The said policies and each of them shall be taken out for one year, and each of them shall have at least nine-ninths to run upon the date of transfer from that date.

(Y) The initial run shall be made on such roads as the purchaser will select, and all damage sustained during the trial run by the automobile and accessories, or any part thsreof, shall be borne by the contractor, provided the oontractor or his representative is present, or if the contractor elects to allow the purchaser to proceed unattended.

(Z) The initial run shall be for a distance of fifty (50) miles out and back by any public highway the purchaser may select, and failure of the said automobile and accessories, or any part thereof, to properly perform shall constitute just and proper grounds for the rejection of the said automobile and accessories, or any part thereof, by the purchaser.

(AA) The clauses as follows are excluded from this contract. (..........), (..........), (..........), (..........), (..........), and the parties hereunto do agree hereby that the said clauses as herein set forth so exoluded are not and shall not constitute a part of this contract.

QUESTION, WHAT IS A CHASSIS?

FROM a discussion recently closed in *Motor Car Journal* (English) it appears that some uncertainty exists even in the trade as to the limits of a chassis, styled and purchased as such. A perusal of the interesting correspondence referred to shows that the issue really centers in the question as to whether tires are to be considered as an intrinsic part of a chassis in the absence of any special reference to, or scheduling of, them in makers' or importers' lists. Most persons seem agreed that steps, mudguards and other accessories appertaining to the body work are not to be expected with a standard quoted chassis. There is, of course, something to be said for the non-inclusion of a set of tires in a chassis purchase. Down to a year or so ago much more might have been urged against their inclusion because, while the consensus of trade practice was to include the tires, it was almost as often the experience that those furnished were unequal to the weight of the vehicle and speeds expected by the purchaser. Hence the practice grew of listing as an accessory stronger tires, or alternatively, by some equivalent means bringing it to the purchaser's notice that the standard equipment had a certain value, and a limitation that were for himself to determine should or should not be obviated at an added cost to himself. Present practice is more or less uniform in the matter of tire sizes for a given category of car. For this we have to thank the tire manufacturers, who indirectly have brought it about by the steps they took to prevent the unfair exploitation of their wares in the manner indicated. That the question of the inclusion or non-inclusion of tires as a standard part of present day chassis has now been raised is partly due to the effect of the tire companies' action, and largely to the stress of competition during the particularly bad and recent period. There is no doubt that precedent counts for much when disputes are referred to the courts, and there is equally no doubt that precedent as to the issue in question is on the side of including tires as a standard part of a chassis' equipment. The fact that, more recently, the practice has been opposed might, or might not, be regarded by the judges as having that sanction necessary to establish in the judicial mind evidence of trade custom; much in the same way that while hitherto and for the present a man's suit of clothes is taken to include the lining, trimmings and buttons, but a woman's costume is usually listed with the same items separately assessed, the sartorial trade might tacitly decide for a common rule in respect of the garments for both sexes. It takes time to establish a precedent having the sanction needed to invest it with a judicial worth, but it takes even longer to upset a precedent once accepted as a rule. Applying this dictum to the case of the tire, and having regard to the circumstances that brought about the recent departure, it may be doubted if a sufficient reason exists for debarring a purchaser from concluding—in the absence, of course, of a direct intimation properly promulgated to the contrary by the seller—that the purchase sum for a chassis is to be taken to include all appurtenances necessary to enable the machine—for such a chassis is until it is transformed into a carriage or other distinctive type of vehicle—to be adequately tested. A chassis without tires cannot be run, and as such lacks one of the essentials to the purpose and style of its construction regarded as a piece of mechanism, carrying an implied warranty of suitability for the purpose intended. No one would contemplate the purchase of a tire-less horsed vehicle, why then exempt a mechanically propelled one from the common rule and precedent?

While the same does not apply to the situation on this side of the Atlantic, all cars here being sold with tires, and with adequate sizes at that, nevertheless, it is of interest as showing the other man's viewpoint.

Great Western plant, where Great Western automobiles are made, depicting a Winter's scene and evidences of activity portrayed by a string of empty freight cars on the siding

Theodore Barnes, Jr., and David S. Hendrick have entered a partnership in Washington, D. C. They will handle the Pullman in that city and Virginia. Mr. Barnes was formerly connected with the Cook & Stoddard Company as a Franklin salesman. Mr. Hendrick was with the Warner Motor Company, agent for the Crawford.

The Pittsburg Automobile Company, Pittsburg, Pa., has removed from its former quarters in the Denny Building, at Seventh avenue and Grant boulevard, to Baum street. Leo Kauffman, dealer in auto oils and automobile supplies, has sublet its former establishment.

A. C. Harrington, for the past nine years with the Packard Motor Car Company, and late of the New York City branch, has left that company to take charge of the sales department of S. J. Wise & Company, New York distributors of the American Simplex.

The Kenny Motor Car Company opened its new building at 1474 Bedford avenue, Brooklyn, N. Y., on the evening of February 12, with an informal reception to the trade and others interested. A complete line of Rambler cars was on exhibition.

The Standard Motor Co. of Boston, Mass., recently incorporated, with headquarters in Boston, is agent in Massachusetts and Rhode Island for the Standard "6" and the Standard "4" types made by the St. Louis Car Co.

The Jonas Automobile Co., Davis Manufacturing Co., and Bartels-Maguire Oil Co., all well-known Milwaukee concerns, have been elected to membership in the Merchants' and Manufacturers' Association of Milwaukee.

Taylor Bros., of Milwaukee, Wis., representing the Hupmobile, have leased quarters at Wells and Sixteenth streets for garage and salesroom purposes. The firm has recently obtained sales rights for the Fiat in Wisconsin.

Henry Ford, president of the Ford Motor Company, who has stood for five years against the A. L. A. M.

L. B. Robinson now has charge of the Studebaker Auto Co. in Louisville, Ky. Mr. Robinson comes from Sioux City, Iowa. The new garage and salesroom is about ready for use.

Charles M. Green has been appointed distributing agent for the Monarch shock absorber. He has opened offices at 1036 Old South Building, Boston, Mass.

The Reliance Automobile Company, San Francisco, Cal., will shortly receive the Knox raceabout, with a 70-mile per hour speed guarantee.

Earlywine & Lewis will handle the Great Western "30" exclusively in Kosciusko County, Indiana, from headquarters at Mentone.

The Iron Range Automobile Co., of Virginia, Minn., is operating a garage and salesroom in that city. It handles the Ford car.

O. R. Hughes, of Marshfield, Wis., district agent for the E-M-F "30," has broken ground for his new garage on City Hall Square.

Taft & Henderson, of Whitewater, Wis., are handling the Ford in several counties of southern Wisconsin.

The Green Bay Motor Car Co., of Green Bay, Wis., has taken the agency for the Maxwell and Regal.

Ward & Dorr, of Whitewater, Wis., have been appointed district agents for the Brush runabout.

Great Western cars will be sold in Champaign County, Illinois, by Cruse Brothers, of Champaign.

The Lambert Automobile Co., agent for the Maxwell car, has taken on the National car.

Hans Sattler, of Sheboygan, Wis., is a new district agent for the Overland.

PERSONAL TRADE MENTION

J. R. Windsor, formerly with the E. R. Thomas Motor Co., Buffalo, N. Y., as special traveling representative in Iowa and the Middle West, has accepted the position of sales manager of the store opened at 1934 Broadway, New York, where A.-K. cars are handled. This company is the representative in the Eastern district for the Pierce-Racine cars, as well as having direct factory connections with the famous German house of Mercedes and the equally famous French makers, Lorraine-Dietrich. The company was formerly located at 3 West Forty-fourth street.

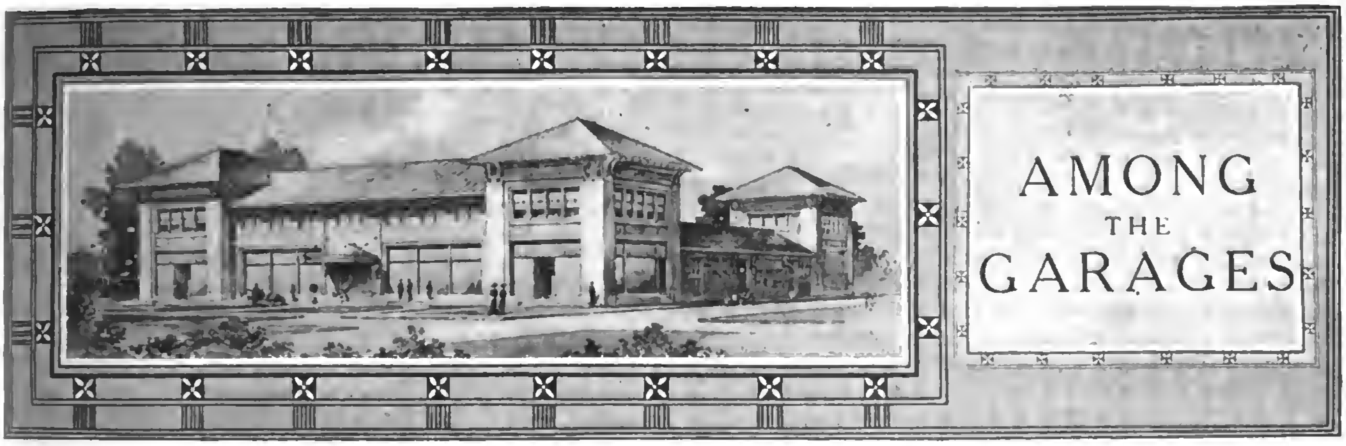
W. H. Wray, Jr., formerly with the Studebaker Co., of New York, has assumed charge of the motorcycle department of the Atlantic Motor Car Co., located at 225-227 West Fifty-seventh street. Mr. Wray is well known as the holder of many motorcycle records, among which may be mentioned the mile straightaway at Ormond Beach, Fla., against time, 44 2-5 sec. The Atlantic company handles, besides the New Era motorcycle, of which Mr. Wray will have charge, the Stoddard-Dayton and Courier automobiles.

J. V. Alden, of the Seamless Rubber Co., is making a tour of the country establishing branch houses. Mr. Alden has just completed this work in Boston, where a branch house was started at 685 Boylston street, under the supervision of A. W. Randall. Leaving there as soon as the business had gained a good start, Mr. Alden proceeded to New York to assist in starting the New York branch, which is mentioned elsewhere, and of which company he is vice-president.

F. A. Hall has been elected as vice-president and treasurer of the Cameron Engineering Company, Brooklyn, N. Y. For the past twelve years he has been manager of the chain block and hoist department of the Yale & Towne Mfg. Co. R. R. Hodgkins will succeed Mr. Hall.

E. H. Whitman, for the past ten years with the National Biscuit Co., has accepted the management of the New York branch of the Seamless Rubber Co., at 2002 Broadway.

Arthur M. Crumrine, formerly automobile editor of the Columbus, O., *News*, has been elected assistant secretary of the Columbus Automobile Club, succeeding Harry D. Sims.



New Baker Electric Garage at Cleveland, which is one of the most up-to-date structures of the kind, in which art, convenience, and economy of management are blended for a most complete whole

The opening of the Alvan T. Fuller Service Depot in Boston, at the junction of Commonwealth and Brighton avenues, marks an important epoch in the local trade, for it stands as a monument to the permanency of the industry and to the building up of the largest retail automobile business in the country. Fifteen years ago Mr. Fuller started in business as a bicycle dealer with a small store on Columbus avenue. He will observe his anniversary on Washington's birthday by inviting his customers to inspect the new service depot constructed at a cost of $300,000 solely for the care of Packard and Cadillac cars, for which he is the agent. It was made necessary by a business which this year will reach $3,000,000 in volume.

The service depot is of concrete and steel, absolutely fireproof, 70 by 341 feet in dimensions and with four stories and a basement. From top to bottom it is equipped with the most modern of machinery for automobile work and with the latest labor and time-saving devices. Every convenience for workmen and administrative force has been installed, the different floors and departments being connected by double stairways, a passenger and a large automobile elevator, electric dumb waiters, pneumatic tubes and telephone system. The administrative and sales department occupies the Commonwealth avenue end of the first two floors, the sales and show room being two stories high and the bookkeeping department being located on a mezzanine. There are private offices for the manager, the superintendent and the technical department.

On the basement level is the boiler room, a washing and storage room for cars belonging to the establishment, locker room for the workmen and lunch rooms. There is also the oil and kerosene room, from which lubricants and kerosene are pumped to all parts of the building. Gasoline is kept in a 1,000-gallon tank outside and pumped to all floors. On the street floor are two wide automobile entrances. This floor is used for minor repairs and adjustments and for the storage of repaired cars ready for delivery to their owners. On the second floor is a stock room carrying parts and accessories valued at $140,000, and a room for the storage of bodies, limousines in Summer and tourists in Winter. On the third floor is the department for the inspection of new cars and the attachment of accessories, the upholstery and top repair department and a large paint shop. The top floor is devoted exclusively to overhauling cars; it is possible for about fifty cars to be worked upon at the same time. On this floor are the forge shop, machine shop, tool room and cleaning room. Every floor has its oil and gasoline room, and there is a special room for recharging batteries and repairing magnetos.

Mr. Fuller will retain his quarters in the Motor Mart in Park Square for sales purposes and the large second-story apartment formerly used as a shop is being transformed into a salesroom for second-hand cars, the salesrooms on the street level being used exclusively for the exhibition and sale of new Packards and Cadillacs.

The Columbus, O., agency of the Oldsmobile and Oakland, which has been financed by H. E. and E. B. Armbruster, has been purchased by G. W. Miller and W. L. Offenbacher. The agency will remain at the same location, 61 East Spring street. The concern expects to sell a large number of cars during 1910.

The Harper Auto Inn & Sales Company, of Wauseon, O., capital stock $20,000, has been incorporated by R. F. Harper and W. J. Harper, two well-known repair men in Fulton County. The new concern will have the agencies for the Buick, E-M-F, and Hupmobile. Plans have been prepared for the erection of a garage 60 by 200 feet, two stories high and fireproof.

The American Machine Co., of Eau Claire, Wis., organized several weeks ago by J. C. Tanberg, a well-known automobile dealer, to manufacture a new type of spark plug of pipestone, chemically treated, has started work on an order for 500,000 plugs from a big motor supply house in Chicago. (Ed.—Can't ascertain name.) The order was obtained by Mr. Tanberg. This and other large contracts have made the present quarters on North Dewey and Wisconsin streets entirely inadequate and until larger shops can be leased other Eau Claire manufacturers will assist in the production.

The Chicago Motor Car Co. announces that it has completed its facilities at the new establishment which has been under preparation for some time, the location of which is Michigan avenue and Twenty-fourth street. The new establishment is so commodious in its appointments that the usual highly efficient Packard service will be the regular thing.

The Wilke Auto & Machine Co., of Sheboygan, Wis., has moved into its new quarters, at Center avenue and North Eighth street. The new garage is 60 by 38 feet in dimensions, with concrete floors, steam heating system and a complete station for recharging electrics. The shop will remain in the Deland building, where it is now located.

G. H. Luch & Co., of Keene Valley, N. Y., is building a garage which will be positively fireproof and 32 by 70 feet. It is proposed to make this garage one of the best in this section of New York. The tool equipment is to include every possible facility for efficient garage work.

Under the new selling arrangement recently adopted by the manufacturers, Fulton, Conway & Company have taken the Louisville and Kentucky agency for the E-M-F car. The concern has established headquarters at 819 West Main street.

Axel Peterson, of Escanaba, Mich., has purchased the Lacomb building, at 303 Ludington street, and will convert it into a garage. Mr. Peterson has had quarters in the Knights of Columbus building, at Ludington and Wolcott streets, Escanaba, for some years.

Trachte & Grahlman, of Johnson Creek, Wis., implement dealers, have decided to remodel their new building and devote a large part to a garage. They are considering several well-known lines, appealing to small towns and country districts soon to be announced.

James Couzens, general manager of the Ford Motor Company, who supports the Ford policy

REALM OF THE MAKERS

Thomas "Big Six" on the road as the jewel in a Winter's setting fully equipped for touring and the instrument for enjoyment to the owner of the wintry weather

It has been definitely settled upon that the Racine Manufacturing Co., of Racine, Wis., which suffered the loss of its plant by fire on December 12, will rebuild in Racine. The first move is the filing of an amendment to the articles of incorporation increasing the capital stock to $400,000 from $50,000. Racine and Milwaukee capital has been interested in the new issue. Contracts have been awarded for the first new building, to be completed in May. L. E. J. Gittings, formerly associated with the J. I. Case Threshing Machine Co., of Racine, becomes treasurer of the company. F. F. Blandin remains as president, and George Jaegers as secretary and general manager. The company is now in temporary quarters, employing 600 of the original force of 1,200 men, and more than 4,000 bodies are now being finished. The company will confine its efforts to the manufacture of automobile bodies, the piano stool end having been taken over by Solomon Grollman, who has incorporated the Racine Stool Manufacturing Co. Every style and type of body will be produced.

The Superior Motor Vehicle Company, which is now located at 150 Michigan street, Buffalo, N. Y., was recently incorporated to manufacture motor trucks and commercial vehicles. The company will build a more extensive plant than was at first intended, and has purchased additional land for that purpose at Elmwood avenue and the New York Central Belt Line. This location is just opposite the plant of the Pierce-Arrow Motor Car Company. Two buildings will be erected, both two stories high; one of them will be 70 by 400 feet and the other 70 by 500 feet. The plant will also include an engine and boiler house. J. Willard Lansing is president of the new company.

The Falls Machine Co., of Sheboygan, Wis., has increased its capital stock from $15,000 to $150,000 for the purpose of engaging in the manufacture of gasoline engines for automobiles on an extensive scale. The greater part of the production has been contracted for by the Warren Motor Car Co., of Detroit. Angelo R. Clark has assumed a large interest in the company and at the reorganization meeting was elected secretary. Gustav Huette was elected president, the other officers being: vice-president, Albert Leicht; treasurer, Walter Koehn. Additions and improvements necessary for the increased production are about to be made.

Business men of Janesville, Wis., have started to raise the stock subscription fund required by the Monitor Motor Car Co., of Chicago, as a condition of removal to Janesville. A block of $50,000 of stock will be distributed in Janesville by a committee consisting of M. O. Mouat, Sanford Soverhill and Frederick Beilhart. Options have been taken on the Green & Sons warehouses as a factory for the manufacture of commercial vehicles in anticipation of success in producing the necessary bonus. A committee visited Chicago last week and was favorably impressed with the Monitor concern.

The first automobile to be produced by the Racine-Sattley Co., of Racine, Wis., well known carriage builders, is being exhibited at the National show in Chicago this week. It had been decided to exhibit only automobile bodies, a recent product of the company, because it was not believed possible for the entire car to be completed. The Holbrook-Armstrong Co., of Racine, delivered the first engine under its contract with the Sattley concern in time for the show.

George Stephenson, of the Stephenson Motor Car Co., Milwaukee, and F. A. Groves, of Chicago, made a trying run from Chicago to Milwaukee, ninety miles, last week. Mr. Stephenson drove a Speedwell and Mr. Groves a Staver. At times the roads seemed impassable and the cars were hidden from sight by drifts. The run was made to test the Staver, which acquitted itself admirably.

Barney Oldfield, in the Cleveland, O., *Press*, recently paid a very high compliment to Mrs. K. R. Otis, Cleveland, noted woman driver. He states that Mrs. Otis beat his record between Cleveland and Buffalo in a Stearns roadster. It is said that during the trip she made the drive from Cleveland to Toledo in three hours and five minutes.

The Mitchell-Lewis Motor Co., of Racine, Wis., has started work on the Special Model S, six-cylinder, cross-country car, to be used by William T. Lewis, chairman of its executive board, in his tour of Europe and Asia with Mrs. Lewis. It will be ready May 1 and will be shipped to the Continent in advance.

The Buick Company recently shipped 40 carloads of automobiles from its Flint factory to Dallas, Texas. This shipment, said to be a record-breaker, went South as a solid train, with a tonnage of 450,200 pounds. One hundred and twenty-seven machines made up the consignment.

The Standard Automobile Company, Kansas City, Mo., is expanding. It has recently taken over a part of the factory at Wabash, Ind., and, in addition, operates two other factories in St. Louis. It is said that all of these plants are now being worked in full capacity.

The Seagrave Manufacturing Co., of Columbus, O., has completed a modern two-story fireproof addition to its plant, which will increase the floor space more than 16,000 square feet. The addition will be used to build the motors of the motor-propelled fire apparatus.

The firm known as the W. N. Best American Calorific Company has retired from business, and Mr. Best now personally manufactures and sells the oil and tar furnaces, of which he is the inventor, at his office at 11 Broadway, New York City.

Col. Charles Clifton, president of the Pierce-Arrow Motor Company, and of the A. L. A. M.

The Decatur Motor Car Company, of Decatur, Ill., formerly the Coppock Motor Car Company, will turn out a line of runabouts in the near future. It is stated that H. W. Meyer will be the manager of the concern.

The Standard Brass & Iron Works, 1820 St. Paul avenue, Milwaukee, Wis., has started the manufacture of a line of tire irons in addition to the extensive repair shop business.

NEWS IN GENERAL

A battery of Cartercars which were placed at the disposal of the "press" when the intelligence department gathered from Detroit and Cleveland honored Buffalo by its presence

Arrangements for the second annual motor show under management of the Milwaukee Automobile Club, in the new $500,000 Auditorium, February 22 to 27, inclusive, are progressing nicely, and General Manager Clarke S. Drake, president of the club, believes that Eastern and Western manufacturers will be pleasantly surprised at the magnitude of the exposition. This year the club will make the show an elaborate social function, and Milwaukee society leaders are taking a deep interest. The Governor and State officials have promised to be present on the opening night, "Society Night," on Washington's Birthday, and will arrive in time for the private view at 2 o'clock in the afternoon. The club will tender a banquet to visiting manufacturing interests, the press, State and municipal officials in the afternoon. This week President Drake and about one hundred members of the club are visiting the Chicago show to get ideas and to solicit further displays.

Senator Timothy Burke, of Green Bay, Wis., member of the special joint legislative committee on good roads, which recently made its report to the Governor, has issued the following announcement, which is welcomed by owners in northeastern Wisconsin:

"While we are waiting for the enactment of our State-aid highway law, let us not forget that we are in a position to mprove the highways of the State, particularly those on heavy clay soils, very materially. I refer to the use of the 'split log drag' used so successfully in this and other States. Chapter 101 of the Laws of 1909 provides that a town board is authorized to have its earth roads smoothed over by the use of such drag, at a cost of not more than 75 cents per mile, a preference to such work to be given to the adjoining landowner or tenant. By the use of the drag the worst kind of clay road can be put in excellent condition at a cost not to exceed $10 per mile. Thereafter the maintenance is a small matter. A split log drag can be constructed by any one at a cost of about $6 or $8."

Thomas B. Jeffery, head of the Thomas B. Jeffery Company, whose fighting ability has rendered him immune

The Wisconsin Secretary of State says there is much confusion relative to the Wisconsin registration law, not a few owners believing it, like the Michigan law, requires annual license fees. The Wisconsin law provides that all who registered prior to June 19, 1909, when it went into effect, must pay an additional fee of $1, and owners registering thereafter must pay $2. About three-fourths of the owners who registered prior to June 19 have paid the additional fee, although the time limit has long since expired. The secretary is giving them plenty of time.

Representatives of the Standard Oil Co. have been visiting several cities of Wisconsin during the last few weeks to interest the common councils in the plan of using crude petroleum for street sprinkling. Figures based on tests in Milwaukee are being used to good advantage, although it is doubtful if the plan will be practicable in cities without asphalt, brick and cement pavement. Milwaukee has contracted for 500,000 gallons of oil for next year's extensive street sprinkling scheme. The city of Oconomowoc, one of the best known summer resorts in the West, has practically decided to follow the plan.

Alfred Johnson, of Menominee, Wis., conducting a large machine and motor car repair shop, has invented a motor sled that has been successful under strenuous tests in deep snows of Northern Wisconsin. The sled is propelled by a pronged driving wheel, under power of a 2 1-2-horsepower engine. It travels from 12 to 25 miles an hour, depending upon condition of the surface.

The Point Spark Plug Co. has just filed papers of incorporation with the Secretary of State at Pierre, S. D. They incorporate for $15,000. The officers are Fred W. Smith, president; Arthur E. Sweet, vice-president, and Guy H. McClain, treasurer. Their new factory is completed and their machinery all installed.

The Milwaukee Common Council, which spent $25,000 for municipal motor cars during 1909, may purchase a motor ambulance for the Johnston Emergency Hospital, if Alderman Joseph P. Carney's resolution is passed. The city now owns a motor police patrol and eight other cars.

At the National Exhibit of Motor Boats, which will open in New York February 19 to February 26, inclusive, there will in all probability be more exhibitors than ever before. It is said that space has been provided for 150 exhibits, and that more applications have been received than can possibly be accommodated.

The Columbia, S. C., automobilists will shortly have an endurance run to Pinehurst. Information indicates that great interest is being taken in this event. Among others, E. W. Robertson, Frank R. Gibbes, G. M. Berry, E. A. Jenkins, W. L. Blanchard, F. S. Terry and Dr. Whaley have promised to enter cars.

In the construction of the new board automobile track at Los Angeles, Southern California, three million feet of Oregon pine planks and beams are used; to hold these together not less than 200,000 pounds of nails and spikes and a few tons of bolts will also be necessary.

The Ohio State Automobile Department has made a ruling which requires all applications for 1910 registration to contain the manufacturer's serial number. This ruling is made for the better protection of automobile owners in case the car is stolen.

The Campbell Automobile Company has moved its home office from Ft. Dodge, Ia., to Des Moines. An amendment to the articles of incorporation, covering this change, has been filed and the move will be complete in time for the Spring rush.

The Tower Grove Motor Car Company, of St. Louis, Mo., has been incorporated, with a capital stock of $5,600, and is to manufacture and deal in automobiles. Incorporators: Thomas W. and H. B. Wiley and F. L. Schleicher.

The Wisconsin Auto Top Company, of Racine, Wis., has started operations in its new plant at Racine Junction. The concern was organized several weeks ago to succeed McAvoy Bros.

The Strawffer-Atterburn Motorcar Company, Louisville, Ky., has been incorporated with a capital stock of $4,000.

Prominent Accessories

Mention of several different parts and accessories is made in these columns which are likely to fill the wants of automobilists, whether recognized or only in the shape of impressions lying dormant. It is often the case that on reading the description of some novel accessory, it will be found to just fit an idea long neglected under the impression that there was nothing to be had to satisfy it. As some makers of automobiles persist in putting nuts in places where it is impossible to reach them with an ordinary wrench, many people will find of great service a special wrench set which can reach into the most remote corners of the mechanism.

The "Stickit" wrench set, a "Bay State" product sold by G. A. Cutter, of Taunton, Mass., is alliteratively described as "seven strong stamped steel sockets strung on a square steel shank." The square steel bar or shank forms the backbone of the set. The sockets when not in use are strung on it; any one desired for use can be placed on the end, where it is held by a spring catch. A ratchet wrench is provided, the hole in which fits the steel shank, and by means of this the shank and the socket on the end are turned. The other end of the wrench will fit the sockets separately without the bar as an intermediary. The upper end of the bar has a knob which may be held in one hand to steady it while the other hand works the wrench.

In application the sets may be used in more ways than might be supposed. The wrench alone fits four sizes of nuts and the sockets will take eleven sizes of nuts and cap screws. The wrench is fastened to the shank full of sockets when not in use by a strong leather strap and shield. This, together with the use of a leather washer on the shank, entirely prevents rattling. The complete set takes up no more room than a large screwdriver, and can be rolled up with the other tools.

The Baldwin Chain & Manufacturing Company, of Worcester, Mass., is now offering to the trade a new and improved steering gear, known as the "Brown." This is a considerable departure from customary types of steering gears, the principal idea in its design having been the correction of the tendency to develop back-lash. In the usual construction the thrusts are taken on the teeth of a worm and sector, or of a pinion and gear, or by other means in which only a line contact is available. In the Brown gear these line contacts are replaced by contact between surfaces, and the surfaces are so broad that the wear on them is practically negligible.

The gear has a bevel pinion mounted on the lower end of the steering column, meshing with a gear; so far the arrangement is conventional. The novelty lies in the method of taking the road shocks off of this gear. To this end the gear is eccentrically mounted on a crank; the crankshaft, which also is eccentric to the gear, carries the swinging arm which connects with the front wheels. The crank referred to has, instead of a pin, a square, or, rather, rectangular lug projecting from its cheek. This projection fits between two segments which with it form a complete circle, and the whole nests in a circular depression in the flange of the gear.

For the gear to move the crankshaft, or for the crankshaft to move the gear, it is plain that as the centers of the two do not coincide, there must be a sliding movement somewhere in the connection; this takes place between the lug on the crank cheek and the segments between which it rests. The leverage, however, is in favor of the gear, as against the crank; thus it will be harder for the front wheels to turn the steering wheel through the crank acting against the gear, than for the steering wheel to turn the front wheels, through the gear acting against the crank. The degree of resistance is regulated by the relative position of the centers.

D. M. Parry, president of the Parry Automobile Company, who is a big fish among the new independents

The parts subjected to the severe shocks coming from the road wheels are only the crank projection, the segments between which it rests, and the walls of the circular depression in the gear flange; all have very wide surfaces constantly in contact. The wear, distributed over such a wide area, becomes negligible at any one point, and, furthermore, the severity of the shocks is taken off the more delicate gear teeth. Thus the appearance of backlash is put off indefinitely.

In addition to its line of automobile tires the Diamond Rubber Company, of Akron, Ohio, has now a complete line of ignition wire and cable. Anyone who has ever had anything to do with automobiles knows how much trouble poor cable can give, and the worst of it is that such trouble is usually hard to find and assign to a definite source. The Diamond 3-8-inch secondary cable has been used successfully for several years by a number of prominent manufacturers with good satisfaction. It has the regular strand of 37 wires of 30 B. & S. gauge, insulated with a high-grade rubber compound and covered with a black glazed braid. The Diamond company bases its claims on its thorough knowledge of rubber chemistry and the ways of applying it.

Among the patents recently granted to manufacturers of automobile accessories is one to the Graves & Congdon Company, of Amesbury, Mass., on its "Luxury" auxiliary seats. The claims allowed are sufficient to cover all of the best points of the seat. Two of the features are the dovetail socket which supports the seat and the feature of construction which makes it easy to swing the seats around while in use. These seats fold back into an extremely small space, the skeleton back models having a thickness of but a few inches when folded. Thus they are desirable for use in cars where space is limited, although it may be necessary to carry extra passengers occasionally. When the seats are taken down they leave no protruding brackets or supports. They are held in the car by means of a dovetail socket and bracket; when the seat is taken down the socket remains, but is practically invisible. Once this socket is in position on the car no tools are required either in the setting up or the taking down of the seats.

"Luxury" seats are made in three different models, one with full padded back and the other two with skeleton backs. All are made in any color leather to match samples, and are stuffed with the best grade of curled hair. The full back model is deep and luxurious; the skeleton back models, although not taking up so much room, have well padded back rests and are very comfortable. The framework is of steel, forgings being used wherever desirable. Each seat may be swung through half a circle.

Despite the recent general improvement in electrical construction, the ignition apparatus of the car is as a rule by no means as immune to injury by water as might be expected. A few magneto makers have seen fit to enclose the mechanism of their product in such a manner as to make it water and dust-proof; there are, however, a considerable number of magnetos in service, most of them, let us hope, of early models, which are put out of business by a good drenching, such as may be experienced in fording a creek, or even by running on a rainy day. For such magnetos one of the best remedies known is the Mesinger magneto cover, made by the H. & F. Mesinger Mfg. Co., 1801 First avenue, New York City.

This is a well-put-together leather casing that fits accurately over the standard sizes of magnetos in such a manner as to form a waterproof protection; in fact, the fitting of the cover is such as to make it almost dust and dirt-proof. The article is made to order, and special sizes of magnetos can be fitted if dimensions are furnished.

Among the windshields which are gaining favor is the "Model," which is the product of the Model Iron & Wire Works, Milwaukee, Wis. This is one of the "universal" persuasion, and has the lower half set back at a permanent angle, especially suitable for runabouts on which there is considerable footroom between the dash and the seat. It has been found that on cars of this type, which are deservedly popular, a shield which stands straight up on the dash affords little or no protection to the occupants of the front seat. On the contrary, the wind currents rush around the shield and often those from the two sides meet directly on the occupants instead of behind them, as they would were the seats set closer. As it is not likely that anyone who has ridden in a car with plenty of legroom would care to go back to the old style cramped position, the problem seemed to be up to the windshield makers, and they evolved the inclined shield.

The "Model" shield has a rather neat locking device, consisting in brief of a crescent or circular sector rigidly attached to the lower half frame, with its center on the hinge line, and a lever on the upper half swinging over the sector and clamped to it in the desired position by a setscrew.

Patents and Processes

The patent law of Denmark is brief and to the point. It provides, among other things, that a patent can be obtained only by the inventor or his assignee. In the case of more than one application the preference is given to the first applicant. Every applicant for a patent not a resident of Denmark must appoint a resident representative. Inventions capable of being utilized in industry or capable of industrial exploitation are considered patentable inventions. Like many other European countries, the law of Denmark provides for three kinds of patents. The first is for patents of invention, the duration of which is 15 years, dating from the date of issue. The second classification is for "dependent patents," for improvements made on inventions patented by a person other than the applicant. The duration of this class of patents is also 15 years. "Patents of addition" comprise the third class, and they expire with the principal patent.

The filing tax is $5.36, while the fee for issuing a patent is $2.68. The annual taxes are as follows: The first three years, $6.70 each; the following 3, $13.40 each; the following 3, $26.80 each; the following 3, $53.60 each; the last 3 years $80.40 each. Applications for a patent must be addressed to the patent commission, at Copenhagen, and must be in duplicate. Together with the application must be filed a description of the invention, which must also be in duplicate. When it is necessary for understanding the description, a drawing, in duplicate, is required, and, according to circumstances, a model, sample, etc. When the applicant is not a resident of Denmark, he must file, in addition to the above papers, a statement showing the appointment of a general representative residing in Denmark, which must be accompanied by the acceptance of the representative. The application, on stamped paper, must indicate the name, profession, and the residence of the applicant, as well as the title of the invention. It must indicate the name of the inventor, and, if it is filed by another, contain proof of the assignment. The description must be sufficiently complete to permit the invention to be carried out. It must indicate exactly what constitutes the claims of the invention. The application and description must be on paper of official size.

One of the copies of the drawings must be on white cardboard of 33 centimeters in height by 21, 42, or 63 in width. All the figures and writings of the drawing must be executed in India ink, in very black and clear lines, without colors, within a line traced at 2 centimeters from the edge, a clear space of 3 centimeters being left at the top. The signature must be placed in the lower right-hand corner. The second copy must be a tracing on muslin. All documents must be in Danish.

The grant is as follows: Preliminary examination as to formalities prescribed and as to the patentability of the invention; publication of the application will call for opposition. The time allowed for opposition is 8 weeks. In case of rejection the applicant may appeal to the patent commission itself, afterward to a special commission to be appointed by the Minister of the Interior. Patented inventions must be worked in Denmark within 3 years from the date of the patent and must not be discontinued for more than 1 year.

The patent law of Switzerland provides that a patent is valid only when granted to the inventor or to his assignee. Persons not living in Switzerland must appoint a representative in that country.

Patentable inventions are new inventions which may be applied in the arts and are capable of being represented by models. Inventions are not considered new which at the time of application for a patent are sufficiently well known in Switzerland to enable a person skilled in the art to execute them. Inventions excluded from protection are those which cannot be represented by models. Methods or processes cannot be patented under the Swiss law.

All applications for patents must be addressed to the federal bureau of intellectual property, at Berne. There must be joined to each application a description of the invention, the drawings necessary for the understanding of the description; the proof that a model of the object invented exists or that the invention itself exists; the sum of $7.72, representing the fee for filing and the first annuity; a power of attorney if the application is filed by a representative of the inventor; a declaration having the signature of the inventor, certified to by a competent authority or by a notary, establishing the right of the holders of the interest, if the patent is not applied for in the name of the inventor; a memorandum of the documents and articles filed.

The application must be written upon a form furnished by the Swiss administration. The description of the invention and the drawings must be filed in duplicate. The application and the documents which are joined thereto must be written in one of the three languages, French, German or Italian. All parts of the application must be in the same language. The title under which the application is presented must designate in a precise manner the subject of the invention.

The applicant for a patent who desires to enjoy the benefit of a time allowance of priority established by international treaty may file the documents which establish the rights which inure to him from an anterior filing. He may also confine himself to mentioning upon the application form the facts serving as the basis for these rights. The description of the invention must make known clearly its import and be so written that one skilled in the art may therefrom carry out the invention. It must terminate with a résumé of the features of the invention which are of special importance. By this is meant the claims of the invention.

The drawings, in duplicate, one copy on bristol board and the other on tracing cloth, must be executed under the following form: Thirty-three centimeters high by 21 wide, 33 centimeters high by 42 wide, or 33 centimeters high by 63 wide. As far as possible the small or medium form should be used. Each sheet of the drawing must be surrounded with a single line drawn 2 centimeters from the edge. It must have at the left, at the top, the name of the applicant and the date of the application, at the right, at the top, the number of sheets filed and the number of each sheet, and at the right, at the bottom, the signature of the person filing the documents of the application. One of the duplicates, intended for photographic reproduction, must be executed upon strong, smooth, and white drawing paper. It must be neither colored nor painted with a wash. The lines must be in good black ink. The hatchings must be separated. The second duplicate must be a reproduction of the first upon tracing cloth and it may be colored. The drawings must not be folded or rolled. They must be sent perfectly flat and not creased. Close attention should be paid to these details, as the law is very strict about compliance with the rules laid down.

There are two classes of patents in Switzerland. The first is known as patents of invention, the duration of which is 15 years, starting from the date of the application. The second class embraces patents of addition, which have the same duration as the principal patent to which they refer. A complete patent of invention is granted only upon proof of the existence of the model. In default of this proof a provisional patent is granted, which can be changed into a complete patent within a limit of 3 years, to date from the day of the application, by furnishing proof of the point in question.

The filing fee is $3.86; the first annuity, $3.86; second annuity, $5.79, etc., increasing $1.93 each year. Patents of addition are subject only to the payment of the fee for filing.

Regarding models: The proof of the existence of the model is shown—models of which are forwarded, the filing being obligatory. These consist of inventions which are essentially composed of substances difficult of identification, inventions which are characterized by properties which ordinary means of investigation do not admit of establishing. Or there may be a permanent deposit of photographs representing the invention in a precise and complete manner or a temporary deposit of models or satisfactory photographs, not to be permanently filed but only for the purpose of comparison. The fee for comparison in the federal bureau is $1.93.

Patents are granted upon proof that the documents and fees prescribed have been filed in the manner indicated by law. In case of the refusal of a patent the interested party may have recourse to the Federal Department of Justice and police within four weeks. Further than this the applicant has no recourse.

Carl G. Fisher, president of the Indianapolis Speedway, on which automobiles are tried out

Some Gooa Reasons for Double Ignition

By W. A. Stiles

COINCIDENT with the development of the modern automobile there has appeared each year a demand for increased reliability and greater efficiency. Slipshod parts, needing constant attention and replacement, no longer meet the requirements for a high-priced, first-class car, or, for that matter, for the cheaper cars of to-day. Among the things which have received a tremendous impetus from this demand in the past few years is the manufacture of the ignition apparatus which is used in this kind of work.

It was not so very long ago that the vibrator coil was in great demand and in almost universal use. Then came the magneto, which developed possibilities not obtainable with the older system, and with the great advantage of producing its own current, thus eliminating the necessity for carrying dry or storage batteries. The high-tension magneto is to-day the result of this development, and is, without question, one of the most satisfactory means of ignition which we have to-day, as its widespread use indicates.

There is, however, the inevitable "fly in the ointment" which is generally found in things humanly constructed, and which, in this case, makes the magneto far from ideal for most cars as a sole means of ignition. This is the fact that the spark generated by the magneto at low speeds is, as often as not, very unsatisfactory for running on high gear in crowded streets, and it also makes cranking rather hard, spinning the engine being the only method in most cases to get a satisfactory spark.

There are, of course, some manufacturers who use a single set, either a magneto or a single spark system in most cases, and, provided the system be a good one and well made, it will give excellent satisfaction without the aid of any other second system. It cannot be said, however, that this represents popular high-grade practice of to-day, even though three or four first-class manufacturers may be using it, since the tendency is decidedly toward the use of the two systems.

Several Dual Ignition Systems in Use

Considering, then, the question of dual ignition, or double ignition, we find that there are different means for securing the same result. There is the one method consisting of a high-tension magneto and a battery set for starting, the latter system distributing the high-tension current through the magneto distributor and using but one set of secondary wires and plugs.

This necessarily tends toward an extremely simple set of wiring and one which takes up very little room, the circuit of which is easily traced out by a novice. The battery part of one of these systems generally works with two to five ordinary dry cells in series, although it is possible to get a fairly good starting spark on even one cell if the primary winding be of low resistance and wound especially to admit the passage of the current under this low voltage.

For this purpose mentioned above, a button or spring switch is usually placed on the dash, by pressing which the current from the battery is sent through the primary winding in the coil. Removing the pressure ruptures the current and, of course, induces an extremely high-tension current in the secondary winding, which is carried to the right cylinder by the distributor.

This starts the engine, when the magneto immediately begins to generate its own current, and the battery may then be shut off. Owing to the short space of time per day in which the battery is in use, its life is greatly lengthened, and even though the starting spark fails to work, owing to poor mixture or other defects, the battery spark is still extremely useful in cranking the car, as it saves the annoyance, as stated before, of spinning the engine to generate magneto current.

In many cases a storage battery is substituted for the dry cell (as the latter is apt to deteriorate whether used or not), and, having so little service put upon it, the former should last for an indefinite time. It will be seen, therefore, that this system is in reality one and one-half systems; that is, while there are two sources of current, there is but one transformer and distributor.

Two Separate Systems Better Known

The other kind of system is, probably, more well known than the one which has just been described, and consists of two separate and distinct ignition outfits. A system of this sort is supplied to-day on practically every high-grade car in the country, and almost invariably consists of a high-tension magneto on one side, and a vibrator coil, unit distributor coil with one vibrator, or a single spark system for the other set.

Some of the most prominent manufacturers give a vibrator coil set with a storage battery, evidently preferring a separate coil for each cylinder, in spite of the greatly increased complication. There is no question, however, that the single unit coil presents many advantages over the multiple coil, and this in every way is efficient. The only point in favor of the former is that by the use of four coils it is unnecessary to have a distributor, but modern design on distributors is so good in the majority of cases that they have become even more reliable than a commutator, owing to the very slight wear which they have in operation, there being no rolling or moving contacts.

It has been objected that a coil is simetimes overtaxed in building up and breaking down the magnetism of the core at high engine speeds while doing duty for all cylinders; but while this may be true for a poorly designed coil, a good one generously proportioned will not limit the engine speed as much as the vibrator or even contact maker will.

As against these slight objections, the decreased bulk, improved appearance of the dash, smaller cost and simplicity would seem to indicate that the more conservative manufacturers will sooner or later fall into line and adopt the latter system as a part of their standard equipment in double ignition.

More Advantages in Two Sets of Apparatus

Considering the respective advantages of these different systems further, it would seem that the equipment embodying two distinct systems would present more desirable features than the single distributor and plug system. In the first place, with the former, it has two contact making and breaking devices, which are absolutely separate and are driven by separate shafts. With the latter system there is but one contact maker, and should it give out both batteries and magneto are useless.

The same thing would happen should the timing gears on the half-time shaft give out; although this is not a very frequent occurrence, nor is it likely to happen. The above objection applies to the distributor as well, which may become short-circuited by water, mud or oil. Now, one of the useful things about a double ignition system is the fact that should the spark plugs foul on one or a part of the mechanism give out the engine may be shifted to the other set.

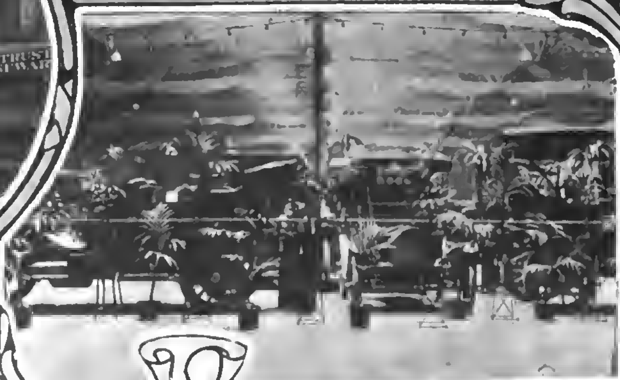
Excellent Features in Every System

We find, then, as with many other things, that each system has certain excellent features and certain limitations, and in this case the following points will influence the buyer. The single coil-distributor set is simpler, has less wiring, and is less expensive. The other method of equipment, which provides two of all the necessary working parts of two systems, undoubtedly offers greater protection against ignition troubles. The question which must be settled is that of expense vs. returns. Without doubt, the ultimate goal is that of a single system which needs no backbone to give reliable results, and this is the sort of apparatus which we will probably see in a short time on all cars, high or low priced.

THE AUTOMOBILE

VIEW LOOKING TOWARDS THE REAR OF THE ARMORY

EXTERIOR OF ESSEX TROOP ARMORY, ROSEVILLE AVE., NEWARK.



ENTRANCE TO THE SHOW

NEWARK, N. J., Feb. 21—Brilliant in dress, comprehensive in detail and with a larger number of exhibits and exhibitors than in the two previous years, Newark's third annual automobile show opened Saturday night. When Colonel Austen Colgate, aide to Governor Fort, and legislative champion of the automobile, declared the exhibition officially under way, 95 cars and chassis, representing more than two-score manufacturers, were in place and 23 accessory exhibits were ready for view. In all, 55 distinct exhibitors occupy spaces on the floor or in the gallery.

As heretofore, the show is being conducted by the New Jersey Automobile Exhibition Company, affiliated with the New Jersey

Top—Packard Exhibit, in Charge of the Newark Branch Office
Middle—Peerless and Locomobile Stands to the Left; on the Right, Mercer, a Native of New Jersey
Bottom—Spalding Showed Both Stevens-Duryea and E-M-F

Automobile Trade Association and the New Jersey Automobile and Motor Club, and is held in the armory of the First Troop—better known as Essex Troop—of the State National Guard, on Roseville avenue.

Profiting by experience, the management left no stone unturned in its effort to make this year's show successful from every standpoint. They were rewarded with unusual interest on the part of the prospective exhibitors and the spaces were soon leased. Later, indeed, it was found necessary to utilize corners, which in the original plan were to have been left open.

Twenty-two of the exhibits are of automobiles exclusively; 23 are devoted to accessories and there is a motorcycle adjunct to the main exhibition. There is a separate section for commercial vehicles and also an aviation department. Fifteen types of cars are shown for the first time in Newark. Additions to the show are expected to-day and to-morrow, so that the total before the coming Saturday, the last day of the show, will reach considerably above 100.

Clothed in orange and blue bunting with palms and other potted plants banked here and there in cases of green, the erstwhile barn-like armory presents a brilliant spectacle. Between each festoon of bunting that covers the girders and brace rods of the structure, is a string of incandescent lights, and shields, painted wheels and groupings of flags lend added attractiveness to the decorative scheme. The tan bark of the floor has, of course, been covered with planking and over all is green carpet. On the opening night the show was crowded.

Finding the demand from auto exhibitors too large to admit of quartering them all on the main floor, the management devoted one side of the gallery to the overflow. Opposite, across the building, is stationed the band, which gives concerts daily, assisted by vocalists. The balance of the gallery is occupied by the accessory exhibits.

In the number of cars displayed, the Maxwell, Pierce-Arrow, Peerless, Locomobile, Buick, Rambler and Packard lead. The majority shown throughout the entire exhibition are stock cars, but there are, of course, exceptions. Only one foreign make is included in the list—the Isotta.

Upon H. A. Bonnell, general manager of the show, and G. H. Raddin, his assistant, fell the chief burden of working out the plans, with the advice of George Paddock, president of the Exhibition Company, and Dr. James R English, its vice-president. Mr. Bonnell is also secretary-treasurer of the company. In their work the officers were aided by the following committees: Space, Mr. Paddock, J. W. Mason, W. H. Ellis, F. L. C. Martin and G. H.

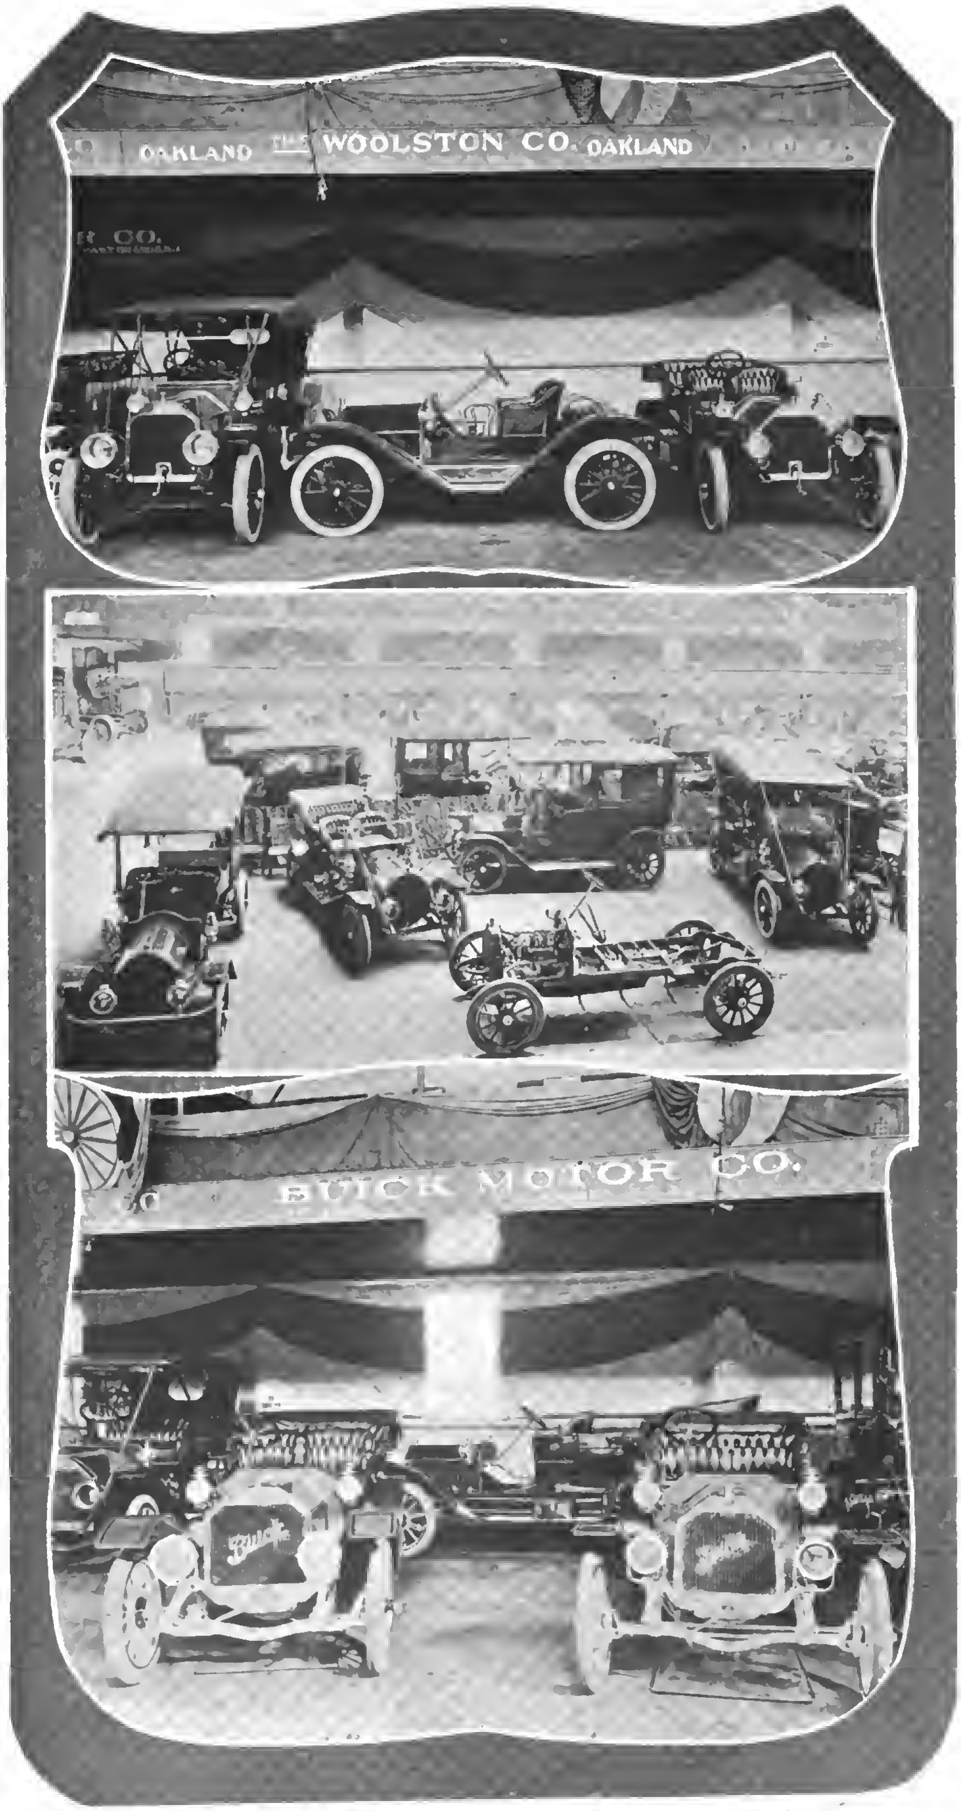
Smith; finance, R. A. Greene, I. M. Uppercu and Mr. Ellis; press, program and advertising, Mr. Bonnell, Mr. Mason, L. B. Zusi and Norris W. Brown; decorations, Messrs. Greene. Zusi and Upperca; entertainment, J. H. Wood, F. A. Croselmire, D. C. Reynolds and Dr. English; aviation, C. E. Fisher. A. B. Le Massena, F. E. Boland and J. F. Lanier.

Not all of the exhibitors are Newarkers. There is a smattering from New York, Jersey City and towns in this section of the State.

Of the manufacturers whose cars are exhibited for the first time in Newark not all are represented locally. Those of the exhibitors who are not Newarkers, however, came from near-by towns. The list of them follows:

Alexander Bruner, Newark, model 4-24 Kline Kar; the Gray Motor Car Company, Summit, N. J., Schacht delivery wagon and runabout; R. D. Norton, Hightstown, N. J., De Tamble runabout and Pickard touring car; Crescent Automobile Company, Newark, Mack (Manhattan) five-ton truck; Terry Automobile Company, Newark, Palmer-Singer 6-60, with gunboat body; H. J. Koehler & Company, Newark, Koehler 40, with torpedo body, and Rider-Lewis type X tonneauette; Woolston Company Newark, Oakland, in three models; Union Motor Car Company, East Orange, Krit runabout; A. Elliott Ranney Company, Newark, Hudson roadster and touring car, and roadster chassis; Green Motor Car Company, Newark. Mercer touring car and baby tonneau; O'Neill Motor Car Company, Newark Paterson touring car and tourabout; J. J. Meyer, Orange, N. J., Auburn model X touring car, and G. F. Little, West Hoboken, N. J., G. J. G. touring car with gunboat body.

Other exhibitors, more familiar to the Newark show-goers, together with their lines, are as follows: Essex Automobile Company, Newark, Ford model T touring car and roadster, Jackson 40 and 50, and Brush Runabout; Detroit-Cadillac Motor Company, Newark, Cadillac demi-tonneau, limousine and touring car: Essex County Overland Company, Overland models 38, 40 and 41, and Marion touring car, roadster and chassis: F. L. C. Martin, Newark and Plainfield, Mitchell models R, S and T, and Hupmobile; Autocar Company, Ardmore, Pa., Autocar touring car; Newark Auto & Engineering Company, Newark, Rambler models 53 and 55, and 55 chassis; Rickey Machine Company, East Orange, Pullman and Marmon; A. G. Spalding & Brothers, Newark, Stevens-Duryea and E-M-F 30; Union Motor Car Company, East Orange, Reo models R and S, touring car and roadster, and Premier, models "Four-Forty" and "Six-Sixty"; Peerless Motor Car Com-



Top—Oakland's Premier Newark Appearance, Staged by Woolston
Middle—More Comprehensive View of the Hall; Cadillac, in Several Models, Occupies the Foreground
Bottom—Buick Had a Good Exhibit of Medium-Priced Cars

Marmon and Pullman Exhibited Jointly Under Agent's Auspices

pany, of New York, Peerless limousine model 27, landaulette 27, toy tonneau 27, touring car 28 and chassis of 27; Greene Motor Car Company, Newark, Locomobile, type "L" touring car, baby tonneau, limousine, landaulette, type "I" touring car, baby tonneau and roadster, and type L chassis; J. W. Mason, Newark, Columbia roadster and Maxwell models E, G, Q, Q1, Q2, Q3 and A, with limousine body after design by Mr. Mason; Paddock-Zusi Motor Car Company, Newark, Chalmers models Forty-J touring car, Forty-J pony tonneau, Thirty-K touring car, Thirty limousine and Thirty chassis; Ellis Motor Car Company, Newark, Pierce-Arrow models "48" suburban limousine, "big-six" touring car, "36" landau, "36" miniature tonneau and "48" stock chassis; J. M. Quimby & Company, Isotta voiturette and Isotta 30 chassis and Pennsylvania model B; Packard Motor Car Company, New York, Packard "Thirty" limousine and "Thirty" touring car and "Eighteen" touring car and chassis; Welden & Bauer, Newark, National touring car, limousine and "Speedway"; Sultan Motor Company, New York, limousine model; New Jersey Automobile Company, Newark, Moline touring car and model M; Buick Motor Car Company, Newark, Buick models 17 and 19 touring car, model 10 toy tonneau and model 10 runabout; Linkroum Automobile Company, Newark, Lozier model H (Briarcliff) and model H limousine and Oldsmobile close-coupled "Forty" and "Limited" touring car; Midland New York Company, models L toy tonneau and roadster.

Eleven types, including two chassis, representing six manufacturers, are shown in the commercial vehicle division of the show, which has a separate part of the building. Of these four and one chassis are the products of the Rapid Motor Vehicle

Little Hupmobile Runabout Kept Company with the Mitchells

Company, of which F. L. C. Martin is the local and Plainfield agent. Newark is primarily an industrial community and the exhibit of these vehicles attracted a large share of attention Saturday. The commercial list follows:

Detroit-Cadillac Motor Company, Cadillac chassis with commercial body by Schildwachter, of New York, after design of C. E. Fisher, manager of the Newark branch; F. L. C. Martin, Rapid 5-7 ton truck; 3-ton chassis, 1 1-2 ton express, 12-passenger sightseeing and ambulance models; Gray Motor Car Company, model D Schacht delivery wagon: Autocar Company, type 21 truck and stock chassis of same; Crescent Automobile Company, Mack Brothers Motor Car Company 5-ton truck; Buick Motor Car Company, one-ton truck.

The accessory exhibits which occupy the entire gallery save for the space reserved for the band at the far end of the armory and that over the main entrance, where the automobile overflow and three motorcycle spaces are quartered, is complete in almost every essential. One can purchase anything from a gilt hood ornament to a fur coat, from a swinging flower vase for a limousine to an inordinately luxurious pair of goggles. Practically all of the exhibitors are Newarkers, many of them manufacturers of the goods they display.

Three makes of motorcycles are exhibited at the show. They are the Yale machine, shown by Frank C. Cornish, of Newark;

De Tamble Runabout and Pickard, an Air-Cooled Bay Stater

Excelsior, exhibited by Carl Bush, of Newark, and the Indian models, of which the H. J. Koehler Company is the local agent.

The aviation section of the show, which opens to-night, will be in the guard room of the armory. Among the exhibits is a monoplane model designed and constructed by Arthur Holland, an East Orange youth. It is 11 x 6 feet in dimensions and its distinguishing feature is a 6-foot spiral spring, with a center shaft of about 5 to 1 gear, which supplies the motive power.

A Witteman glider will also be shown, together with an 8-cylinder monoplane from F. E. Boland, of Rahway, N. J. The former is 20 x 4 1-2 feet. A 44-foot Wright type will also be included in the exhibit, with more than a dozen models furnished by the West Side Y. M. C. A., of New York. Accessory exhibits will include a display by the Hartford Rubber Company and a propeller by the Requa-Gibson Company, of New York.

The section will be officially opened by Wilbur R. Kimball, secretary of the Aeronautic Society, of New York, who will give an illustrated lecture. C. E. Fisher planned and has charge of the exhibit.

Members of the New Jersey Automobile and Motor Club have appointed a committee to organize an aviation section to be known as the Aeronautic Society of New Jersey. It is proposed that the affiliated organization shall be a regularly incorporated body, with complete management of its own affairs, funds and property and elect its own officers and directors from its membership. The objects of the proposed society are the promotion of aviation in general and the fostering of aeronautic meets and other matters connected with the sport.

Membership will not be limited to persons belonging to the Motor Club, but the dues will be larger. The committee consists of W. Clive Crosby, president of the automobile club, chairman; C. E. Fisher, F. E. Boland, W. R. Kimball, A. B. LeMassena and J. F. Lanier.

BINGHAMTON'S AUTO SHOW NOTABLE

BINGHAMTON, N. Y., Feb. 22—Nobody looking in upon the first annual automobile show held under the auspices of the Binghamton Automobile Club and the Chamber of Commerce would ever dream that Binghamton was a town of merely 50,000 souls. That information is about the most surprising imaginable especially after a detailed examination of this splendid exhibition in the State Armory which was thrown open to the public for one week, beginning last night.

Paterson "30," Another to Make Initial Newark Appearance

To be specific there are nearly sixty completed cars shown on the floor, 59 exactly, with about eight or ten demonstrators in attendance at the front door. Then there are seven ancient monarchs illustrative of the progress of the industry since 1899, and an aeroplane in the riding hall of the basement.

The first surprise is occasioned by the electric sign stretched across the street in front of the armory. This is a gorgeous changeable electric device that puts to shame many of the famed Broadway signs. Inside the decorations are military in design in keeping with the surroundings. The profusion of bunting and flags is well arranged without being overdone and the lighting is great. On the main drill floor, nothing but completed cars are to be found, except that the official headquarters of the club are located right at the entrance. There are 32 makes of cars, one of the newcomers of which is the Imperial, made in Jackson, Mich. This is shown by F. E. Spawn Co. for the first time at any of the local New York shows. The Binghamton Cadillac Co., unable to get a stripped sectional chassis from Detroit cut away one of their own stock cars and mounted it.

A. E. Wheeler, Syracuse district manager of the Franklin Co., has sprung the real novelty of the show in the demonstra-

National Fours Were Featured by Weldon & Bauer Company

tion line. He is driving about the streets, the glass hood electric-lighted Franklin six the same as furnished to each district manager, but in addition to that phase evolved about the cleverest scheme to show the air circulation that could well be imagined. Standing at the front end of the hood is a boy with a bee smudge bellows in which is burning punk, such as is used in handling honey bees. The boy works this smudge so that it flows constantly into the hood of the car, where its movement can be easily traced as the suction fan in the rear of the cooling case draws the air currents by the cylinders and expels them underneath the car. All during the show this car stands directly in front of the armory. The basement houses a varied and interesting line of accessories, motorcycles and bicycles. Here, indeed, is a novelty. Frank T. Abbott and the Waldron Drug Co. have large exhibits composed entirely of bicycles and they attracted lots of attention by their sheer novelty.

The Riding Academy, just to one side of the basement proper, proved a live magnet with its most interesting exhibits. First is shown a string of old cars starting with the motor from the first car ever seen in Binghamton. This was an old two-cylinder, two and a half horsepower car with gears directly attached to the connecting rods, which were concentrically attached to a shaft that held a big solid iron wheel upon which ran a rope belt. The affair without a name was owned by Joseph P. Noyes in 1898. Then, in succession, indicative of the years in which they were seen, are a steam locomobile roadster, Oldsmobile runabouts, three-wheel Knox, Pierce runabout, chain-driven Searchmont, Jones, Corbin, Packard, and a later Pierce. In the center of the Academy is the first aeroplane ever seen in Binghamton. It is a Curtiss, with an American-British four-cylinder engine.

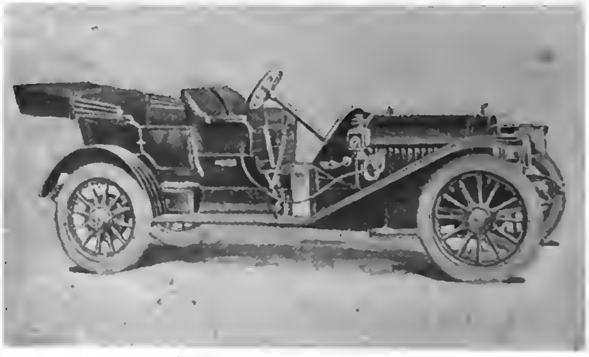
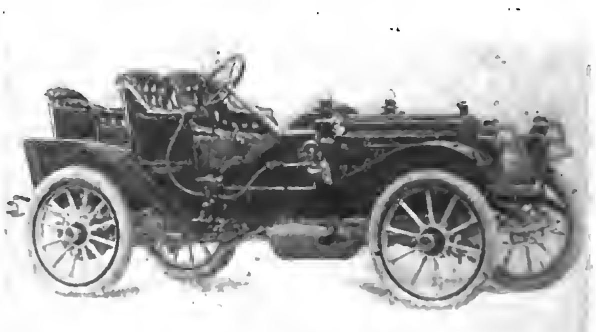
MANY AUTOMOBILES

Many makers of automobiles now look upon the rural districts as representative of a considerable portion of the conditions which lead to stability, and at the Chicago Show, just closed, it was a well-recognized fact that a large percentage of the actual buyers of automobiles came from the farms and the many small towns which are scattered through rural districts. These buyers prove to be a little troublesome to the salesman who is incapable of tersely stating the facts in relation to his product. The farmer is quite unfamiliar with machinery, and he knows perfectly well that it is a considerable distance from a farm to a



Locomobile Model L Baby Tonneau



Packard "18" Four-Cylinder Runabout

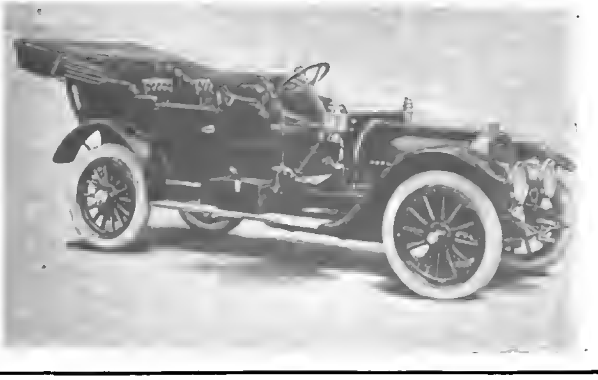
Peerless Model 27 Four-Cylinder

LOCAL makers of automobiles are all at the Cleveland Show with the exception of one, there being 21 different makes of automobiles exhibiting 104 separate models of cars. The Central Armory, which is dressed for the occasion, was taken in hand by the Cleveland Automobile Show Company, under the direction of Frank W. Philips, President; Harry S. Moore, Vice-President; Hobart M. Adams, Secretary, and Clarence M. Brockway, Treasurer. In addition to the exhibition of the automobiles, the accessory makers are there in force, among which will be found 26 firms of local fame, displaying their wares under the most advantageous conditions, and presenting a spirit of unusual enterprise.

The committee in charge endeavored to make this last effort the equal in all respects to the other shows of the year, and the decorations, which included rich and splendidly arranged trimmings, were merely as drapings for banks of cut flowers, which were displayed to the best advantage through the lavish use of electric lights.

For the convenience of patrons a neatly decorated Tea Garden was located on the main floor, and adequate provision is made in the form of rest rooms and refreshment quarters adjoining. The Aeronautical division, which now seems to be a regular thing in connection with the display of automobiles, comprised an aeroplane which hung in the center of the Armory, and since it is the first equipment of this character displayed at a show in Cleveland, it is attracting notice.

The outlook, based on the conditions which led up to the show, and considering the initial attendance, is extremely promising, and among the important phases which are distinctly noticeable is the presence of out-of-town (rural) purchasers in force. There never was a time before in the history of Cleveland automobile exhibits when the attendance was sufficiently peppered with out-of-town purchasers to be noticeable. These prospectives are well in hand with funds; they have yet to enjoy a great familiarity with the automobile situation, taking it as a whole, although it is easily discovered by salesmen that each one of them is fairly keen about some one or two makes of automobiles, and is in hand with book lore to a marked extent.

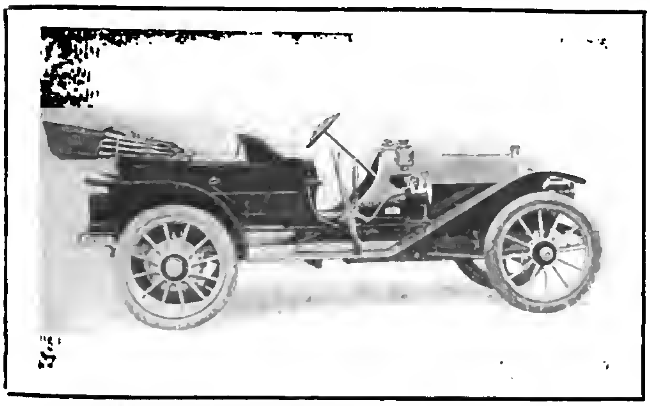


Royal Tourist Four-Cylinder Touring

SHOWN AT CLEVELAND

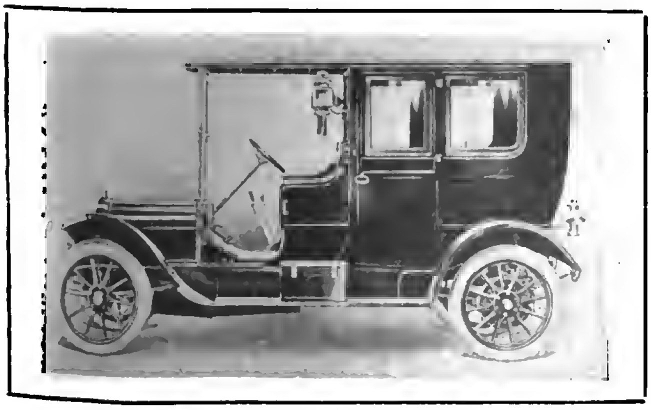
repair shop, and he relies upon his own little forge for even his permanent repairs.

To convince this class of buyer that he can afford to indulge in a given make of automobile is to show him that it is free



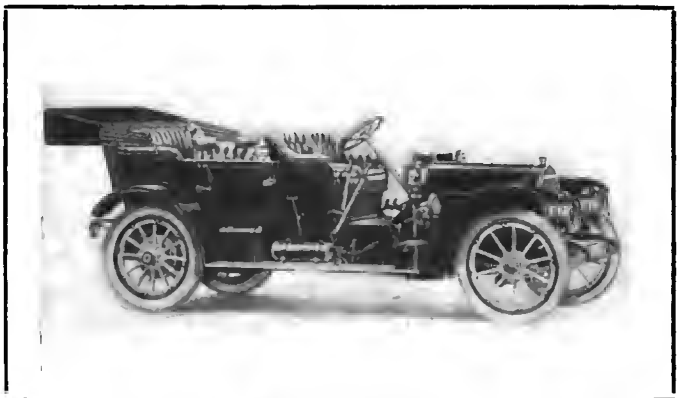
Stevens-Duryea Model XXX Four-cylinder

Studebaker-Garford Model G-7 Limousine



White Model G-B Gasoline Limousine

from that class of complications which puts it beyond the pale of repairers, considering a simple forge, a machinist's kit and the materials as bar stock, which are likely to abound the country over. Simplicity of design, ample clearance and straight line work will naturally appeal to this class of customers, and if the surplus of automobiles are to go to the farm and the small



Stearns 30-60 Four-Cylinder Touring Car

country village, it is safe to conclude that the design features must appeal to the men who must maintain the cars, rather than to have them towed to a garage repair shop.

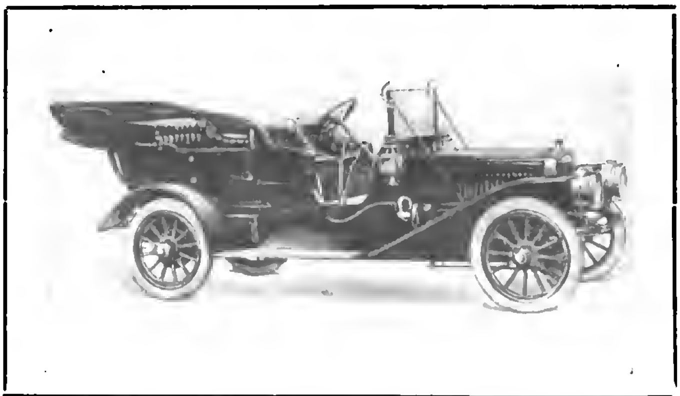
The Cleveland Show is bringing this class of purchasers to the surface, just as they were in evidence at Chicago, and probably as they appeared to some extent, at least, in all the shows of the year. This condition is the best evidence of the healthy growth of the automobile, and the extension of its use into the zone of practical application which is the highway to the greatest measure of stability. Until this condition could be measured, there were a great many autoists who labored under the impression that the automobile took on some of the phases of the bicycle, which proved to be a mere fad, and the life of a fad being limited, there were some who persisted in maintaing that this characteristic followed the automobile much as a spectre.

The automobile exhibitors are made up as follows:

EXHIBITORS OF AUTOMOBILES AT CLEVELAND SHOW

Applebaum Brothers	Detroit Electric
Auto Bug Company	Auto Bug
Baker Motor Vehicle Company	Baker Electric
Chisholm & Phillips	Stevens-Duryea
Cleveland E-M-F Company	E-M-F
Chadwick Company	Chadwick
Derain Motor Car Company	Derain
Ford Motor Car Company	Ford
Gaeth Automobile Company	Gaeth
Hoffman Auto Company	Locomobile
Moore, H. S.	
Peerless Motor Car Company	Peerless
Rauch & Lang Carriage Company	Rauch & Lang
Royal Tourist Car Company	Royal Tourist
L. S. & M. S. R. R.	
Studebaker Auto Company	Studebaker-Garford
Standard Automobile Company	Standard
F. B. Stearns Company	Stearns
Sterling Motor Sales Company	Sterling
White Company	White
Winton Motor Carriage Co.	Winton
Simplex Motor Car Company	Simplex (Americsn)

This show, despite the number of its exhibits, and the fact that it includes so many of the important makes of automobiles. is but one of the important events which will go to Cleveland for this year. The Eighth Annual Show of the Cleveland Automobile Club is yet to come. It is scheduled to open on March 5 and to run for seven days. It is commonly expected that the second show will be a record breaker, and if expectations in this connection are realized, Cleveland will take high rank.



Winton Model 48 Six-Cylinder Touring

General View of the Grand Rapids, Mich., Show, Illustrating the Decorative Scheme; Reo Occupies the Foreground

Furniture City Exhibition Attracts Attention

GRAND RAPIDS, MICH., Feb. 19—One of the largest buildings of Grand Rapids, devoted usually to the exhibition of the furniture for which the "Furniture City" is famous, is now devoted to the exposition of another of the country's great industries, namely, the automobile, and it is apparently attracting more attention than the finest products of the furniture field ever did. In short, Grand Rapids is having its first automobile show, and that it is an overwhelming success, is evidenced by the fact that ever since the opening night, when the aisles were literally packed, several thousand people have visited the show daily.

Although this was the first local show, the management seems to have learned the art, by the use of electric lights, bunting and flowers, of producing a beautiful spectacle. Festoons of electric lights and miles of pale green bunting outline the various exhibits, forming a pleasing color effect. Various arc lights, tastefully decorated with green leaves, add to the brilliancy of the scene, and in the center of the hall a large dome of electric lights has been placed. Palms and high bay trees have been used at intervals throughout the building to good effect, and the gallery set apart for the bands and orchestras is literally hidden from view with green stuff.

There are 31 exhibits in place, comprising 80 cars and requiring 30,000 feet of floor space. Pleasure cars predominate—in fact only four commercial cars were shown, these being light delivery wagons made by the Duplex Power Company, of Charlotte, the International Harvester Co., Buick Motor Car Co., and Angus Auto. Co., which makes the Fuller.

It was gratifying to see the large representation of Michigan-made machines. Especially prominent were the six-cylinder Austins, a native Grand Rapids product.

Immense American Flag, Covering the Entire Ceiling, Was the Central Feature of the Buffalo Show

Buffalo Show Breaks All Attendance Records

BUFFALO, Feb. 19—All previous records in attendance and gate receipts were broken by the "Old Glory" Automobile Show, which closed to-night with the band playing "The Star-Spangled Banner." At the close, the 8,000 lights were turned out in the Stars and Stripes which gained the eighth annual automobile show of the Automobile Trade Ass'n its distinctive appellation.

The total attendance for the week is estimated at 50,000. This is pronounced to be about 32,000 more than for the show of 1909. The attendance for the closing night was greater than that of any of the preceding nights, and a new record was set of a larger patronage on every succeeding night since Wednesday, instead of diminishing at the close as in former years.

It has been the consensus of opinion among exhibitors that there was never held here before so remarkable a show in point of sales. President Charles F. Monroe, of the Trade Association, and Secretary J. J. Gibson stated that upon a careful canvass it was learned that the number of cars actually sold and which could be attributed solely to the show was 152.

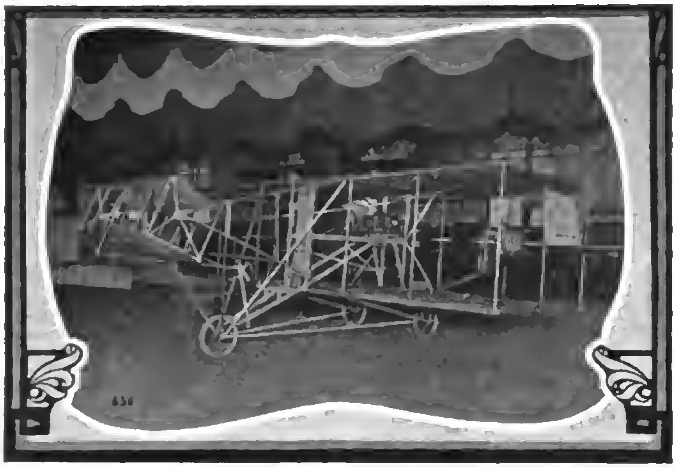
Chauvière Propeller, a Popular French Construction

BOSTON, Feb. 19—The first aeronautic show in America, with the possible exception of a small affair held in New York last Fall in connection with the Business Show, is now in progress in Mechanics' Building, completely filling the main hall. There are some fifteen full-size aeroplanes on exhibition, besides several gliders and any number of models and parts.

Exceptional among the other machines because of its perfect workmanlike finish was the biplane built for A. M. Herring, the former partner of Glenn Curtiss, by W. Starling Burgess, the yacht builder. Although following the lines of the biplane made familiar by Curtiss, this is said to differ in some important features, notably the apparatus for securing lateral stability. This, unfortunately, was not exhibited, the reason assigned being that it is not yet covered by patents. The landing gear of this machine consists of a single long central runner with two short spurs, one on either side, just under the main planes. Another unusual feature is its equipment with a four-bladed propeller, a type which few aviators believe in.

In its general construction the Herring-Burgess machine showed the effects of careful labor. The design of the framework is well worked out, attention being called to the manner in which two bars, starting from the front tip of the machine, extend backward to carry the aviator's seat and then support the motor on their rear ends. The vertical struts between the planes are well shaped, tapering at the ends where not so much stiffness is required.

Herring-Burgess Biplane, of Neat and Workmanlike Design



Ericka Biplane, a Recent Springfield, Mass., Product

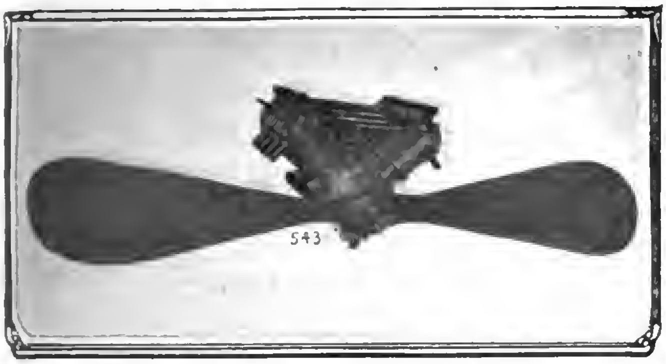
Near View of Herring-Burgess Machine, Showing Details

One of the few monoplanes shown is the "Morok," made by a New York concern and offered for sale at a reasonable price. It is equipped with a four-cylinder 30-horsepower Harriman motor, weighing 315 pounds. The frame is of wood and tubing. Lateral stability is secured by a device often advocated in print, but never before, as far as is know, seen on a full-sized machine; that is, by sliding wing tips. These are two small planes, one at either end of the main plane; normally they do not project over the main surface, but they can be made to project at will, thus increasing the supporting surface on either side desired.

The only drawback to this method seems to be in the distribution of weight. Sliding out the plane on either side certainly increases the supporting surface on that side, but it also increases the leverage distance of the weight of the sliding plane itself; thus the efficiency of the surface must be considerably reduced.

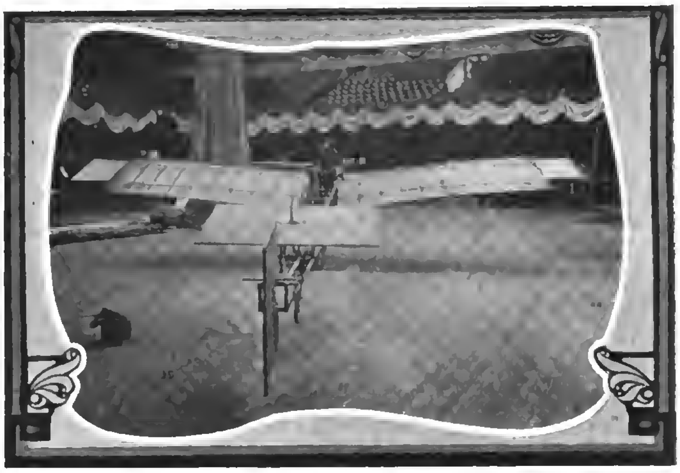
The "Morok" follows standard monoplane design in having the propeller in front and the horizontal and vertical rudders in the rear. The planes are carefully trussed both above and below. The control resembles somewhat the Antoinette design, with two hand wheels; one controls the extension planes, and the other the horizontal and vertical rudders.

L. C. Erickson, of Springfield, Mass., shows the "Ericka" biplane, following rather closely the lines of the Curtiss machines. It has a triangular running gear, with three wheels, the single one being in front. The planes are 20 by 7 feet, very flat, with rocking auxiliary planes for the lateral control. These are actuated by the sidewise movement of the back of the operator's seat, following the natural swaying of his body. There is a double horizontal rudder in front, and a vertical rudder in rear, in connection with a rigid tail plane for stability. The framework is of bamboo and tubing. The motor is a standard auto-



Easton Eight-Cylinder Aeronautic Motor and Propellor

Biplane Following Wright Lines, Shown by F. P. Shneider



Morok Monoplane, with Sliding Auxiliary Balance Planes

L. A. W. Aero Motor and Propeller, Mounted on a Pivot

mobile design, of the Buick make, apparently taken bodily from a 22-horsepower Buick runabout; it drives a two-bladed wooden propeller at the rear.

The L. A. W. Motors Company, of Providence, R. I., shows a biplane equipped with a "L.A.W." motor, the initials, it is said, signifying the possibilities of the motor's use on land, air and water. This motor is a six-cylinder, two-cycle rotary, air-cooled. The cylinders are mounted radially about a central hub, with their heads to the center. The piston pins, instead of connecting rods, are provided with ball bearings of large size, forming rollers; these run around in a circular ring set eccentric to the cylinder hub. This eccentricity causes the pistons to move in and out of their cylinders as they rotate about their hub.

The inlet for the fresh gas is through the central stationary hub, which has a port which registers in turn with ports in the cylinder heads. Ignition is accomplished without any electrical apparatus, except for starting. In operation, each cylinder fires the one next to it by means of a by-pass through the central hub, which admits some of the burning gas into the cylinder just ahead. A single spark plug may be fitted into this port.

The biplane on exhibition at the L. A. W. stand has one of these motors mounted on pivots, in such a manner that its shaft, with the propellor attached, can be made to point upward or downward at will, and thus guide the machine.

F. P. Shneider, of New York, has two craft on exhibition, one a 35 by 40-foot biplane after the Wright model, and the other a 30 by 35-foot Curtiss model. Stanley Y. Beach, also of New York, has two monoplanes, one on the Antoinette model and the other following Blériot lines. Other exhibitors of complete machines are the Aerial Exhibit Company, of New York; Elmer Burlingame, of Boston; Southworth & Merz, Brooklyn, N. Y.; Mr. Caines, of Boston; the Easton Cordage Company, Easton, Pa., and G. S. Haywood, of Hyde Park, Mass.

The lighter-than-air division is rather scantily represented. The spherical balloon "Boston," the property of the Aero Club of New England, is shown inflated. It is two years old, and during its life has made 45 ascensions, carrying 95 passengers; it has been in the air a total of 85 hours, covering 1,251 miles. Its capacity rating is 35,000 cubic feet. A. Leo Stevens, of New York, and the Boston Balloon Company also exhibited.

Among the parts and accessories most interesting is the Chauvière propeller, the make used by many French aviators. It is of laminated wood in six layers, very scientifically constructed, to secure great efficiency in air displacement. The Easton Cordage Company exhibited a special aero motor, eight-cylinder in V-shape, with a two-bladed wooden propeller directly mounted. The motor is of good design, departing from the automobile standard in but few respects. Valves are all in the cylinder heads with a single cam and rocker for each cylinder.

Models are almost innumerable, but those of the Harvard Aeronautical Society deserve mention. This body, composed of students and instructors at Harvard University, had on exhibition the planes of the biplane "Harvard I," which it is constructing, the glider "Naiad," and models of the Wright biplane and the Blériot monoplane. The Technology Aero Club, the Boston Y. M. C. A. and the International School of Aeronautics, of New York, also exhibited.

GASOLINE	**ALONE IS NON-EXPLOSIVE** **LIQUID WILL QUENCH A FIRE** **CONTAINS NO OXYGEN AT ALL**
WATER	**FORMS AN EXPLOSIVE GAS** **MAY ADD MORE FUEL TO A FIRE** **CARRIES SUFFICIENT OXYGEN**

STARTLING as these statements seem to those who accept the common prejudices against gasoline, they are nevertheless well substantiated. This unfortunate fuel is the most maligned and mistreated substance known to chemistry. It is commonly regarded as akin to nitroglycerin in its explosive qualities, to the extent that some people refuse to ride over a tank of it; at the same time it is splashed about carelessly in filling tanks, and allowed to run into drains and saturate wooden floors, and then blamed when it follows its natural tendencies.

Taking up these statements in order, first may be considered the explosiveness, or non-explosiveness, of gasoline. It is unfortunate that the engines in which gasoline is used should be so commonly miscalled "explosion" engines; their true name is "internal combustion." As this distinction indicates, gasoline never explodes, although it may burn with great rapidity and violence.

Properly speaking, an explosive is a substance which, without the help or presence of any other substance, may, by heat or concussion, be caused to undergo chemical changes which result in the production of gases of much greater volume than the original substance. The violent expansion of these resulting gases forms what is known as an explosion. The chemical change which results in the formation of these gases is oxidation, or burning; but if this is to be accomplished without the interposition of any other substance, as specified in the definition, the oxygen must be contained in the explosive substance itself.

The presence of oxygen in true explosives, such as gunpowder, nitroglycerin and its derivatives, the various forms of dynamite, may be seen from their chemical formulas appended herewith. (Oxygen is represented by O, hydrogen by H, carbon by C, potassium by K, nitrogen by N, mercury by Hg, sulphur by S, etc.) It is to be regretted that the formulas of nitroglycerin, guncotton, etc., are too complex to be of much use in this connection; but the explosion in all cases is the result of self-contained oxygen.

Gunpowder, a familiar explosive, may be taken as the example. It is a mixture of charcoal (carbon), sulphur and saltpeter; the latter, which contains the oxygen, forming about three-quarters of the whole. The chemical changes which form the explosion are the oxidation of the carbon, sulphur and potassium, and the liberation of free nitrogen; all the products, with unimportant exceptions, being in gaseous form. These gases occupy from 1,000 to 1,500 times the space of the original gunpowder, and consequently exert an enormous pressure on any vessel which contains them.

Now it remains to be seen whether gasoline should be classed with these explosives. In the first place, gasoline is not a definite chemical compound; it is the trade name for a mixture of various liquids known as hydrocarbons. In the United States these components are practically always of the methane or paraffin series, and hexane and heptane form the greater proportion. As a rule, the higher the "degree" of the gasoline, the larger the proportion of hexane and pentane; the lower the "degree," the larger the porportion of the heavier constituents. Commercial paraffin is composed of still heavier members of the series, which are solids; the lighter members, as methane and ethane, are gases. In England and on the Continent, where "petrol" and *essence* are sold in specially compounded brands, there is often an admixture of other hydrocarbons, given below under the heading "Suggested Fuels."

No great knowledge of chemistry is required to see that these hydrocarbons contain no dangerous amount of oxygen. In the case of ether and the alcohols the lone atom of oxygen is quite harmless among the greater number of atoms of carbon and hydrogen. It is obvious that for any oxidation of these fuels to take place, there must be some admixture of a second substance, in this case, of course, air, which is a mixture of oxygen and nitrogen. In the presence of air, these various hydrocarbons may oxidize into gases. The exhaust of a gasoline engine is composed of some 80 per cent. of nitrogen, taken in as air and left unchanged by the combustion; some 10 per cent. of carbon dioxide; and some 5 per cent. of oxygen and a residue of carbon monoxide, hydrogen, methane and miscellaneous hydrocarbon vapors, left by the incomplete combustion. These changes, although resulting in the formation of gases at high pressure, are quite distinct from the phenomenon known as explosion.

Gasoline in itself, therefore, is quite harmless; it is incapable of any chemical change except in the presence of oxygen, or some oxidizing agent. It is unfortunate, in one way, that air, the most common oxidizer, is quite universal in its presence; but even here the possibilities of combination of the two are not so great as might as supposed.

The operation of a gasoline engine depends on the evaporation of gasoline, the quality which causes it to break up into minute particles and mix with the surrounding air; and this evaporation takes place constantly at all ordinary temperatures. However, when evaporation ceases after it has proceeded to such an extent that the gasoline vapor (that is, the liquid particles) are 15 per cent. of the air which carries them (at a temperature of 60 degrees Fahrenheit). Air in this condition is said to be saturated. This is the condition which normally exists in a tank of gasoline, as carried on an automobile, or in a stationary tank in which air is used to force the gasoline out. Now it is an important fact that gasoline vapor in the saturated condition will not burn.

Neither will gasoline vapor considerably below the saturation point burn, nor again vapor extremely thin. The range of combustible proportions is very limited. From the saturation point, at which the volume of vapor is 15 per cent. of the volume of air, the proportion must be reduced to 5.5 per cent. of vapor, corresponding to one volume of liquid gasoline to 3,500 volumes of air, before the mixture will burn; and when the proportion falls below 2 per cent. of vapor, or one volume of liquid gasoline to 10,000 of air, the mixture again becomes non-combustible. The narrowness of these limits has been impressed on many an automobilist who has striven long and anxiously to make his carbureter provide a combustible mixture. A large number of the stalled automobiles formerly so common a sight were mute witnesses to the harmlessness of gasoline.

A body of gasoline open to the air will be covered by strata of air in various stages of permeation with gasoline vapor. A layer immediately over the gasoline will be in a state of saturation; and from this the proportion of gasoline vapor will diminish gradually in all directions. There must, therefore, be somewhere in the vicinity of the gasoline a layer of air carrying the right proportions of vapor for combustion. A flame, or other sufficient source of heat, introduced into this layer will ignite it, with more or less disastrous results.

This layer of combustible vapor is the sole source of danger in connection with gasoline. The fact remains that the liquid itself and most proportions of its vapor positively will not burn. If poured on a fire gasoline will extinguish it just as surely as water will; the conditions to be observed are, of course, that the gasoline must be in sufficient quantity and applied quickly enough to reduce the temperature below the point of ignition of gasoline vapor, before that vapor has a chance to form. It has been proved by actual experiment that a lighted cigarette dropped into a can of gasoline will simply be extinguished.

Naturally, it is not recommended that gasoline be used to the exclusion of water for extinguishing fires, nor even that readers try for their own edification the experiment with the lighted cigarette. The "No Smoking" sign in garages should always be observed and rigorously enforced. The point to be made is that gasoline is dangerous only when the victim of rank carelessness and abuse.

Having now proved the three contentions made in behalf of gasoline, it may be edifying to consider the results of a careless use of water, apparently the most innocent of substances. In the first place, water is an ingredient in the manufacture of a combustible gas as dangerous as the vapor of gasoline, namely, water gas. When suitably enriched with hydrocarbon vapors, this is frequently used as illuminating gas, in place of coal gas, as it is cheaper to manufacture. The process consists, in brief, of forcing water, or steam, through a red-hot mass of coal. The water is broken down and partially unites with the carbon of the coal, forming a mixture of carbon monoxide and free hydrogen. When ignited, this oxidizes into carbon dioxide and water vapor.

A gas plant is by no means necessary for the formation of this gas, as any municipal fire department will witness. Any form of carbon will do to replace the coal, and water, if the temperature is sufficiently high, will quickly furnish the steam. In the case of burning buildings, dangerous "back flares" frequently result.

Newspaper accounts of garage fires and burning cars usually contain some line to the effect that "the gasoline tank exploded with frightful violence, scattering the flaming liquid in every direction." Here the distinction has been neglected between the explosion of the tank and the explosion of the gasoline. If the above arguments have been followed the reader should have no remaining doubts as to the impossibility of the latter. A tank of gasoline, however, can explode in the same manner that a steam boiler can. The heat of the surrounding fire, in the case of a burning car or building, will vaporize and expand the gasoline in the tank, and unless the means of escape are sufficient, the pressure thus generated will cause the tank to burst with considerable force. The dispersed vapor is then in a favorable form to mix with the suitable proportion of air and catch fire.

In the handling of gasoline the cardinal principle to be observed is to prevent vaporization if possible, or at any rate to keep the vapor in the saturated condition. Standard forms of gasoline storage tanks keep the part of the tank not occupied by gasoline full of water. As the two do not mix, the gasoline, which is the lighter, remains in the upper portion of the tank, and cannot form vapor. Pumping in more water forces the gasoline out, as required.

For automobile tanks this idea has not been found practical. In the gravity-feed type of tanks a vent-hole is provided which admits air as the gasoline is used up; in pressure-feed tanks air, or exhaust gas, is forced in to force the gasoline out. Whenever air fills the part of the tank not occupied by gasoline, it becomes saturated with gasoline vapor, and so is harmless. The danger comes in the filling of the tank, when a quantity of this saturated vapor must be ejected from the tank and allowed to mix with the outer air. This is the time when the match and the cigarette get in their best work.

Methods of extinguishing gasoline fires are quite commonly known. Water must never be used; in the first place, it does not put out the fire, and in the second place it makes it worse. The latter is because gasoline floats on water, and so is spread out in a more favorable form for vaporization. Sand and earth, on the other hand, absorb the gasoline and prevent its vaporization. Wood-pulp is one of the best materials for absorbing gasoline, and has been recommended as a filling for all storage tanks. It will absorb 55 per cent. of its own volume of gasoline, and thus absorbed, the gasoline is absolutely harmless.

In laying down rules on any subject it is always better to have the reasons well understood; when chauffeurs and garage men thoroughly understand the nature and properties of gasoline, rules for its handling will be less needed. In some directions improvement in the construction of automobiles will be of avail. When the carbureter that needs no priming is invented, and all dust pans may easily be taken off for cleaning, one considerable source of danger will be removed. The custom of drawing off gasoline from the tank for cleaning purposes should also be discouraged; not only is it expensive, but it usually results in the scattering about of gasoline-soaked pieces of waste. Non-explosive though gasoline may be, care in its handling is never wasted.

CONSTITUENTS OF GASOLINE

Liquids of the Methane Series

General Formula	C_nH_{2n+2}
Butane	C_4H_{10}
Pentane	C_5H_{12}

Black Gunpowder $C+S+KNO_3$ (10 to 15 per cent each carbon and sulphur, 70 to 75 per cent saltpeter).

Picric Acid $C_6H_2(NO_2)_3.OH$.

Ammonium Nitrate NH_4NO_3.

Nitroform $CH.(NO_2)_3$.

Mercuric Fulminate $Hg_2C_2N_2O_2$ (used with KNO_3).

Nitroglycerin, Guncotton, Celluloid, Collodion and other explosives are similarly formed, all containing their own oxygen.

STANDARD FOUND BY AVERAGING 1910 CARS

CONCERNING the advanced mechanical features which prevail, and those which are not advanced but of interest, it will serve well the purpose to tabulate and average the differing features, basing a keen analysis upon such tabulation. Taking as a basis of this tabulation and analysis the three big shows, namely, the Palace and Garden in New York and the Chicago Show, will have the merit of arriving at a result at once. This process, on the other hand, will have the disadvantage of counting in some cars twice and thus accentuating their mechanical features. But, to look at it otherwise, the total number of exhibitors at these three shows tallies almost exactly with the total number of builders now existing in this country, so that at the risk of a slight—a very slight—amount of accuracy this method at once arrives at an equivalent average for all cars built in the country. In other words, the exhibitors showing for the second time just exactly balance those who did not exhibit at any one of the three shows.

The appended table, then, gives what might be called, for want of a better name, the four standard American cars. Four are obtained by following the price classification which has hitherto been followed in similar tabulations. That is to say, the cars as a whole have been divided into four great price classes, namely, all cars below $1,000 in price; all cars listing at approximately $1,500; all cars above this, but not exceeding in price $2,500, and, finally, all cars above this figure, which latter selection has been labeled the $4,000 class because of the close approximation to this figure in the average.

FOUR AVERAGE CARS OF 1910 TAKEN COLLECTIVELY.

Classes	$1,000	$1,500	$2,500	$4,000
Wheelbase In.	96	109	114	124
Wheels, Front	31.0	33.3	33.8	35.6
Wheels, Rear	31.0	33.3	34.2	35.7
Price of Car	$867	$1,412	$2,161	$3,849
Motor				
Cylinders—One	2.8			
Two	29.4	4.8	1.3	
Three				
Four	67.8	93.5	89.1	61.1
Five				2.6
Six		1.6	9.5	36.2
Average Bore	3.92	4.17	4.32	4.77
Stroke	4.19	4.46	4.76	5.13
Ratio	1.070	1.070	1.101	1.075
Formula Horsepower	20.4	26.8	31.1	45.4
T type Cylinders	7.7	9.8	18.7	41.4
L type Cylinders	87.0	82.2	57.7	35.6
Overhead valves	5.3	8.0	11.0	21.6
Cyls. Cast—Indiv.	56.9	54.9	36.6	34.2
Pairs	7.7	24.3	56.6	65.1
Block	35.6	20.7	6.6	0.6
Water Cooled	91.8	93.4	95.3	95.1
Thermo	67.2	34.6	20.6	4.9
Pump	24.9	57.9	74.4	90.2
Air Cooled	8.2	6.6	4.7	4.9
Ignition—H. T. Single	63.0	22.5	27.6	10.4
Dual	26.5	42.1	32.4	46.1
Double	10.0	35.3	38.5	39.0
Make and Break				3.5
L. T. Single			1.4	1.5
Carbureter—Gravity	100.0	87.3	90.3	60.2
Pressure		12.7	9.6	39.7
Lubrication—				
Compression Oiler	2.6	1.6		
Pump	62.4	75.6	66.5	64.4
Gravity Pump	8.2	6.6	1.5	
Mech. Oiler	16.1	11.2	26.6	35.6
Flywheel Circ.	8.2	4.9	5.3	
Clutch-Mult. Disc.	53.6	47.9	45.4	48.2
Cone	38.3	47.1	33.0	40.8
Exp. Band	2.6	1.6	12.2	3.8
Contr. Band			8.1	4.6
No Clutch	5.0	3.3	1.3	2.6
Transmission—Sel. 2	13.2		1.3	
Sel. 3	19.3	64.0	87.8	51.9
Sel. 4		1.6	3.3	41.6
Prog. 2	19.3	3.3		
Prog. 3	2.6	3.3	4.7	3.9
Plan 2	44.3	21.0	1.4	
Plan 3		3.3		
Friction	5.0	3.3	1.3	2.6
Drive-Shaft	81.7	88.5	97.3	91.8
Chain	18.3	11.5	2.6	8.1
Weight	1,229	1,939	2,283	3,192
Weight per Horsepower	60.2	72.3	73.4	70.3
Horsepower per 100 Lbs.	1.66	1.38	1.36	1.51
Price per pound	$.705	.728	.946	1.205
Price per horsepower	$42.50	52.69	69.48	84.78
Pounds per dollar	1.49	1.37	1.06	.83
Power per dollar	.0235	.0190	.0144	.0118

American cars as a whole, then, would be divided into four groups, and their mechanical features would average up to the figures given in the table, these being expressed in percentages of the whole number in the group where possible, and otherwise in exact averages.

It will also be pertinent to the discussion of the features of American cars as a whole to consider the exhibits at the three shows as three separate groups, each with its own average. Considered in this light, it will be possible to sketch out wherein each one of these three groups of cars has influenced the final average, and wherein it has been influenced by the other groups to make up the final average.

That this is pertinent to the subject is shown by a single instance. Thus, in the oft-discussed matter of ratio of bore to stroke: At the Palace show the cars in the $2,500 class had an average bore of 4.41 and an average stroke of 4.89, giving an average ratio of bore to stroke of 1 to 1.108, thus showing that this class of makers does not incline very forcibly to the lengthened stroke. Then at the Garden show, in the same price class, the makers average up to 4.2 bore and 4.6 stroke, a ratio of 1 to 1.095, showing that this group of master builders inclines even less to the long stroke than does the previously mentioned class. At the Western show the averages were 4.35 bore and 4.80 stroke, a ratio of 1 to 1.103. This is neither the largest ratio nor the smallest, and when all three are compared with the one given in the all-American table, 4.32 bore by 4.76 stroke, a ratio of 1 to 1.101, it is seen that the Palace show brought the average up, while the tendency of the Garden show exhibitors was to bring it down. The Chicago show, on the other hand, simply served as a balance, neither raising nor lowering it.

After this brief excursion into the probity of this method of classification of the cars, it will be well to examine into the results which the method gives.

The crying need of the country to-day—that is, in the automobile business—is for standardization, not alone of the little things, some of which have already been slightly investigated, but also of the big things, such as cylinder sizes, wheelbase, tires per effective power or per given weight of complete cars, size of shafts to carry a given power when a specified material is used, size of axles, and a number of others. These have as yet not even been dreamed of by automobile builders, and when this is brought to their notice they will doubtless say that such a move will take away all originality. In reply to that unspoken argument, it will suffice to call attention to the electrical standardization methods, which have penetrated even farther than this in a business of equal or greater bigness. More than that, now that it is done, every electrical manufacturer in this broad land is glad of it; his worries are lessened, his supplies are minimized in number, he carries a lessened number of parts in stock. In these and many other ways, which lack of space prevents mention of, the business as a whole, although it resisted the work at first, is now bigger, better, healthier for the change. So it would be, and in fact must be, with the automobile business, and that, too, at a time now not very far distant.

As for the accompanying table, and the matter to follow, these simply represent what might be called the existing attempts at a standard, representing as they do an average of all the cars now made in this country. Viewed from that slant, it will be well to look into the details. Four standard cars, so-called, are given. These were selected according to price classification, the four divisions being made up to $1,000, from $1,000 to $1,500, from $1,500 to $2,500, and all above the latter figure.

In the first or $1,000 class the wheelbase is 90 in., the wheels are 31 in. in diameter all around, and the average tire size, not given in the table, is 3.2 in., or approximately 3 1-4. The price of this car averages to $867.

Passing next to the so-called $1,500 car, the wheelbase is 109 in., the tires are 33.3 in. in size all around, or approximately 33 1-2 in. In price the average strikes $1,412. Next above this, the wheels are 33.8 in. in front, and here is seen the first difference, the first appreciation of the differing work of the two sets of wheels, the rears being 34.2 in. These two are taking the nearest even fractional figure 34 in. fronts and 34 1-4 in. in the rear. The price average is $2,161.

The last or highest class has a wheelbase of 124, in which respect attention is called to the fact that the increment of wheelbase in the four classes is very close to 10 in. per class, the closeness of price of the two middle classes being the cause of the only wide divergence from this. Here the wheel sizes again show a difference, fronts being 35.6 in., roughly 35 1-2, while rears are 35.7, roughly 35 3-4 or 36.

Passing on to the motor details, the number of cylinders is given the preference as to position, since this represents the real thing for which the money is paid—that is, other things being equal, no man would pay the same money for a one-cylinder car as for a four-cylinder machine, choosing the multi-cylinder every time. In the fact that other things are not equal lies the claim for business of the makers of a lesser number of cylinders than six, the greatest number now in daily and constant use.

The good old single-cylinder horizontal is a thing of the past. the Cadillac, Reo, Buick and others which have made this type world-famous having been discontinued. In their place, but few single-cylinder automobiles are now built, foremost among which may be mentioned Brush, with a single cylinder engine, but set vertically. To compare with the many excellent, fast and durable French, German and English single-cylinder runabouts, there is not an American motor car on the market to-day. While Brush and the others, taken collectively, make up but 2.8 per cent of the whole number of makers, Brush alone on the basis of this year's production will amount to nearly 5 per cent of the estimated total production, this Detroit maker having figured on an output of 10,000 cars for the year 1910.

Passing on to the two-cylinder engine, it is found that this type of prime mover is comparatively popular in the lowest priced class, amounting as it does to the comfortable total of 29.4 per cent of the whole number. It would be interesting to find out just how much of this figure is given over to the two-cylinder vertical and how much to the two-cylinder opposed. It is doubtful if any of these cars uses a two-cylinder inclined motor, a type which has met with little favor on this side, although comparatively popular abroad for low-priced cars. The rest of this class is made up of four-cylinder engines, the exact figure being 67.8 per cent. When the price is considered, averaging $867, this really is an astonishing fact, for the rate of value per dollar expended is so much greater than was the case but two years ago as to cause wonderment. That quantity production has had much to do with this is self-evident, as is also the machine tool builder's part in it. Without many of the very latest up-to-date machines, fully automatic in their action, this sort of a thing would be impossible. This figure shows, too, that the man who is waiting to buy an automobile "when they get cheaper," basing this on the ratio of value in the bicycle, is badly off, for there will never be a time when the actual value per dollar invested will be greater than to-day, considering the manufacturer's profit at a fair and equable rate. In the connection of value with result, it might be called to the attention of the reader that the aforementioned car, which sells very much below the average, has done much to pull the aforesaid average down to this low level.

Power always interests, as does the source of it, so the cylinder sizes interest, too. In this low-priced standard car the average bore, considering all engines, one, two and four cylinders, on an equal basis, is 3.92 in., while the bore is slightly larger, 4.19 in. The nearest fractional sizes come in sixteenths, but expressed in millimeters, this engine would be 100 by 106. The formula power would amount to 20.4, or in even numbers 20 horsepower. Attention is called to the ratio of bore to stroke, this being but 1 to 1.070, or very little more than an even bore and stroke. In this again we find little or nothing to compare with the long stroke voiturettes of abroad, with the stroke running from 1 1-2 up to 2 times the bore.

Passing along to the points of design, the L type of head is preferred by no less than 87 per cent of the makers, while the T head and the overhead-valve type divide the rest, these being nearly on a par as far as numbers are concerned. This landslide to the valves-all-on-one-side engine is explained in part by the lower cost of foundry work and the decreased cost of the final engine, due to the elimination of one camshaft and the lessened machine work on both cylinders and crankcase in this type.

Of vital interest to the foundry, although having a big bearing upon the design as a whole, is the shape and size of the cylinder casting. That is to say, whether it is of a number of individual castings, one for each cylinder, a smaller number of pairs, that is, two cylinders cast as one, cylinders in threes, or cast in a block. The smallest car shows a predominance of the single cylinder castings, although in this, the matter of cost, as exemplified by the type of cylinders is reversed, the mostly used individual castings costing more per engine in both the foundry and machine shop than the cylinders in pairs. Next in order, numerically, comes the block casting. Evidently the swing of the pendulum has been away from the single casting of late, the large number in the older class represents the older makers, while the newer form of construction attaches itself to the newcomers. At any rate, it is a surprising fact that next to the single castings in order of popularity comes the cylinders cast in a block. The percentages of the two are respectively, 56.9 and 35.6, leaving but 7.7 per cent for the paired castings, or as they were once called, siamesed.

Air versus water for cooling purposes is settled by the percentages, which are 91.8 for water and 8.2 for air. Excepting only gravity feed to the carbureter, there is the biggest percentage given to any one feature in the whole list, with the single exception of the higher priced cars, on which this same percentage is increased slightly. As for the water cooling, itself, this is separated into the two schools, those favoring the natural or thermo-siphon method of circulating the water, and those who stick to the pump for driving the water. In this priced car, where first cost, simplicity, and small number of parts are all large and weighty points upon which to hang a selling argument, it is to be expected that the simpler system would predominate, which it does by the large percentage of 67.2. The other method has many followers, however, as is shown by the number, 24.9 per cent.

When it comes to ignition, there is no such unanimity, three systems of wide divergence dividing the total number of makes. These with their percentages are: high tension single, 63.0; high tension dual, that is, magneto used as a timer for the battery current, some one feature thus being utilized in both systems, 26.6, and finally, double or two separate and distinct systems, 10.0. Considering the price of the cars in question, the latter is a source of wonderment, that is, from the viewpoint of how the manufacturer is able to do it.

One might reasonably expect that none of the cars in this class would have pressure feed from a rear gasoline tank to the carbureter, this being both expensive and complicated. Such is the case, the gravity feed being set down at 100 per cent, or on all cars in the class.

In the matter of lubrication, the makers begin to show less of standardization than has been shown in previously discussed features. Five methods of lubrication are listed, and each one of these has a following, somewhat limited in some cases, it is true, but nevertheless, adherents. To mention the five and their respective percentages: compression oiler, 2.6; circulating pump, 62.4 by far the largest, and also, the only close approximation to a standard; gravity feed from a container, which is kept filled by a pump, 8.2; mechanical oiler with numerous leads, 16.1; and flywheel circulation of the oil, that is to say, splash, 8.2.

Under the heading of clutches, while five different kinds are mentioned, but four have friends among the very small car makers. These show considerable unanimity, in that two types together make up 92 per cent of the whole. These are: the multiple disc with 53.6 per cent and the cone clutch with a following of 38.3 per cent. The rest is divided into: expanding band, 2.6 per cent, and no clutch at all (friction transmissions) 5.0, while the contracting band is not used.

One might expect—and with good reason—that the cheaper to build planetary transmission would be found strongly intrenched in this class, yet such is not the case, emphasizing the "value for money" previously spoken of. Two and three-speed selective gears together total 32.5, while the four-speed gear is not used. Then the two and three-speed progressives add their quota of 21.9, making about 55 per cent. This with the 44.3 planetary and 5.0 friction makes up the whole.

Shaft drive is very much in the majority, which is all that can be said, the chain-driven variety having the handsome total of 18.3 per cent. Coming down to the weight, this is somewhat difficult to ascertain with accuracy, but a figure is given. This is but slightly over 1,200 pounds, which amounts to the very low figure of 60 pounds per horsepower, or put otherwise, 1.66 horsepower per every hundred pounds of dead weight. As to cost of power, and weight, the former works out to $42.50 per horsepower, while $.705 seems to be fair per pound.

Passing to the next larger model, the more popular $1.500 machine, the opinion as to number of cylinders has increased, nearly all makers fitting four, to be exact, 93.5 per cent. In the still larger model, an increasing loss to the sixes is noted, so that the number of fours falls to 89.1, this increasing along the same lines to 61.1 fours and 36.2 sixes, in the largest car. The same gradual but noticeable increase in bore and stroke is noticed, the ratio of the two remaining practically near 1.1.

Cylinder shapes show a gain in T heads and overhead valves, both at the expense of the L head, so that the latter becomes in the three larger models: 82.2 per cent, 57.7, and 35.6, losing the lead in the latter case to the T head. Similarly paired cylinders gain at the expense of both block and individual cylinders, the former in fact practically disappearing in the highest priced car. Cooling as to air versus water stands in about the same ratio, with a very slight gain in favor of water. As to the method, however, the simpler thermo system loses ground constantly. Ignition is mostly by the systems which permit of a choice of two, dual and double together amounting to nearly 90 per cent. In this, the more expensive cars show a few, a very few evidences of the low-tension system. Some increase in pressure feeds for the fuel is noted, but this is a variable, rising only to drop again, going on up the scale. Lubrication, too, shows a peculiar variation, but the mechanical oiler of multiple leads, and the pump circulating scheme, as more satisfactory and positive, show a continuous increase. In clutches, the diversification, which gives the advocate of standardization much to talk about, is very noticeable, the two leaders in the small car class both losing in favor of the expanding band, contracting band and friction transmission.

Transmission trend is shown in the overwhelming number of selectives as against all others combined, this figure being nearly 94 per cent. Strange to relate, chain driving loses ground rather than gains, the percentage dropping from 18.3 for the smallest car to but 8.1 for the most expensive, reaching a still lower point of 2.6 for the $2,500 car.

Weight, of course, increases, but slightly faster than does the power, as shown in the figures of weight per horsepower, and horsepower per hundred pounds, the latter in particular showing the high relative power of the very small, extra light cars and the very large and heavy cars. Price goes steadily upward, whether it be total, price per pound, or price per horsepower. It would seem, at first thought, that the two latter would be quantities which would remain fairly stationary, but such is far from the case, the price per pound going steadily up to over one dollar in the big cars, while for the same class the price per horse-power reaches the top-notch figure of nearly $85.

While not actually presenting the four standard American cars, because there are no such things to be presented, this table and the remarks upon it give some food for reflection, incidentally pointing out more strongly then ever the need for standardization, the universal standardization which will give a similar weight, power and ability for the same amount of money.

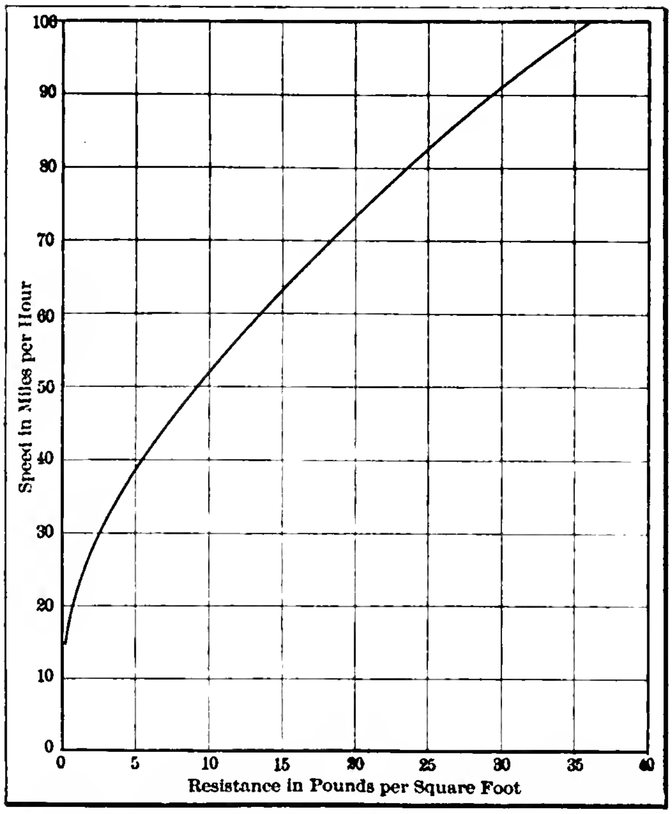

Chart Plotted to Show the Increase in Wind Resistance with Speed

EFFECT OF WIND AND AREA ON SPEED

At speeds below twenty miles per hour the effect of wind resistance, so called, is below the noticeable point when an attempt is made to measure its magnitude. Considering surfaces at right angles to the normal plane of travel of the automobile, the wind resistance, as measured in pounds per square foot, while it begins to show at about fifteen miles per hour, raises slowly, reaching about 2½ pounds per square foot when this speed is doubled. Further increases in speed result in a rapidly increasing rate of resistance to travel as measured in pounds per square foot, and at 60 miles per hour this effect is slightly over 13 pounds. Increasing the speed again up to ninety miles per hour increases the effect of wind resistance so that it is represented by the considerable figure of 29 pounds per square foot, approximately. The curve here given shows the results of tabulation involving these factors and illustrates the necessity of treating with this question of front area.

There are two possible remedies in an attempt to reduce the ills of wind resistance, one of which lies in the greatest possible reduction of front area, and the other involves wedge shapes and a smooth exterior. If cooling depends upon a radiator in front, the area of the radiator exposed is, of course, regulated by the cooling requirement. A certain amount of air must brush against the cooling surfaces, so that the air molecules will sponge heat out of the cooling water as fast as it is enabled to penetrate the walls. The ability of the radiator is increased with the speed of the car up to about twenty miles per hour, but beyond this point front area, from the cooling point of view, is not a factor. The front area, as regulated by the radiator, therefore, must be such as to permit a sufficient weight of air to brush over the cooling surfaces at a speed of twenty miles per hour.

EFFECT OF HEAVY CHARGING ON PASTED LEAD PLATES*

By HUGH RODMAN

SUCH plates, in service, and not subjected to abuse, fail by reason of the active mass softening and silting from the face of the plates to the bottom of the jar. This disintegration is probably due to one of three main causes:

First. An untangling of the set, crystalline mass due to the cycle of changes from peroxide to sulphate and back to peroxide, to which a portion of the active material is subjected with each charge and discharge.

Second. To solution of the set, crystalline lead compounds and precipitation thereof as loose pulverulent compounds. This follows from the formation of concentrated sulphuric acid in the pores of the plates during charge, this dense acid dissolving lead sulphate and reprecipitating it upon contact with the diluted acid at the surface of the plates.

Third. The solution of crystalline lead compounds and reprecipitation as non-crystalline compounds, due to the formation of persulphuric acid at the surface of the positive plates during the gassing period.

The first source of trouble may be helped in two ways, by less frequent charging and by starting with more thoroughly set or crystallized plates. It is obvious that with a battery capacity of forty miles and a ten-mile run on two successive days, if the charge is deferred until the end of the second run the active mass will have been subjected to one cycle of change of crystallization instead of two cycles, which would have followed recharging after each partial discharge.

*Paper read at the semi-annual meeting of the Society of Automobile Engineers, New York City, January 4 and 14, 1910.

The solution of lead compounds by dense sulphuric acid may be partially overcome by the use of thin and porous, rather than thick and dense plates, thus giving the sulphuric acid formed during the charge a chance to mix more easily with the dilute, free acid outside the plates. Slow charging will, obviously, serve the same purpose.

The disintegration, due to persulphuric acid, may be lessened by infrequent, complete gassing charges. It is generally believed that the gassing charge must be given occasionally, but there seems to be no necessity for doing so more than once in, say, two weeks. Certainly it is harmful to gas the plates freely at the end of each charge.

Altogether the best scheme of charging, suggested by theory, is: First, to charge at a moderate rate; second, to recharge only after several partial discharges; third, to give the gassing charge only occasionally.

These conclusions are fully borne out in practice. The life of batteries is increased by moderate charging, say, the four-hour rate to begin with, and half that rate at the end of the charge. Longer service is secured by infrequent charging. It is not difficult in most installations to defer charging until after several partial discharges, provided these discharges have not stretched over too long a time. A charge following two or three partial discharges on successive days is far better than a charge following each partial discharge.

Fairly complete charges, say, up to 2.4 volts per cell with the current equal to about half the four-hour rate of discharge, gives longer life to plates than where gassing follows each charge.

MAXWELL SAND BLAST CLEANING PROCESS IN DETAIL

THE refinement of the old-time sand bellows, the modern compressed-air sand blower, is used by the Maxwell-Briscoe Motor Company in cleaning and smoothing various machine parts and particularly in preparing the steel bodies of Maxwell cars for the painter's brush.

In order to free the surfaces from all traces of oil, rust, etc., they are subjected to a blast of fine sand, which is driven against the hard metal with great force. The abrasive action thus set up removes all slight inequalities and results in a surface of ideal smoothness. In order to make it impossible for sand to enter the workman's lungs he is attired in an air-tight helmet into which air is pumped from an outside reservoir.

In the illustration the workman may be seen sanding one of the transmission gears, the tank for the air, with its pipes and gauges being clearly visible behind him, in the corner of the room. The latter, it will be noted, is of very cheap construction, as it would not be advisable to have it otherwise, the sand not being particular about automobile parts, but attacking buildings when properly directed toward them just as readily.

The sand blast is the invention of B. F. Tilghman, of Philadelphia, and made its first appearance at the American Institute Fair, in New York City, 1871. The material used may be common sand, powdered quartz, emery, or any similar substance composed of hard and sharp particles, and may be blown by a blast either of air or of steam. A jet of sand impelled by even the blast of an ordinary fan will give glass a "frosted" finish in a few seconds and will cut wood quite rapidly. With a jet issuing under 300 pounds pressure a hole can be cut through a piece of corundum, the material used in grinding wheels, 1 1-2 inches thick, in 25 minutes.

With the expenditure of 2 horsepower in compressing air, 2 square feet of scale on the surface of ordinary steel plates can be removed per minute, the surface being then ready for galvanizing or painting. A hundred pounds of castings can be cleaned in 10 or 15 minutes with a 2-horsepower jet.

Maxwell Sand Blast Operator At Work on Small Castings

INCRUSTATION DEFEATS COOLING

RADIATORS, however efficient they may be when they are new, become fouled by foreign matter which is suspended in the water when it is put into them, and, if the radiators are not large enough properly to cool the motors without evaporating water, it is but a matter of a short while when the accumulation of foreign matter will be sufficient to defeat efficient cooling,

Elimination of Impurities from Water

(A) For sediment; filter or blow off.
(B) Bicarbonates; add caustic soda and boil water before use.
(C) Sulphates; add barium chloride and settle.
(D) Grease; add slacked lime and filter.
(E) Organic matter; precipitate with alum and filter.
(F) Carbonate of Magnesia.
(G) Carbonates; add barium chloride and settle.
(H) Chlorides; add carbonate of soda.
Note.—The proper time to take advantage of any of these processes is before the water is placed in the cooling system; once the surfaces are coated over with a hard crust, they will be beyond cure. Chemicals will damage the radiator.

even assuming that the trouble may not extend to the point which will induce knocking and pre-ignition.

If a radiator is so efficient for its purpose that water will not have to be added to make up for that which boils away, the quantity of impurity which will accumulate in the system will scarcely be enough to notice, even after several years. If, on the other hand, the system must be replenished daily, the amount

Temperature of Calcareous Precipitations

(A) Carbonate of lime; minimum temperature 176 degrees F.
(B) Sulphate of lime; minimum temperature 284 degrees F.
(C) Chloride of magnesium; minimum temperature 212 degrees F.
(D) Chloride of sodium; minimum 324 degrees F.
(E) Carbonate of lime is held in solution of bicarbonic acid.
(F) Heating drives off the carbonic acid and the salts will then precipitate.
(G) Sulphate of lime is most soluble in water at 95 degrees F.
Note.—If a radiator is large enough to properly cool a motor, it is highly improbable that the temperature will increase sufficiently to deposit any but carbonate of lime.

of foreign matter which will accumulate will soon result in trouble, and, contrary to some of the preachings, the type of radiator employed will have little or no influence on the result.

Since a little sediment will accumulate over the surfaces of the system in the course of time no matter how commodious the radiator is, it stands to reason that it should be liberally proportioned for the work it will have to do, in order that it will be large enough to properly serve the purpose when the surfaces become slightly coated.

The effect of incrustation is most marked; if the scale is 1-16 inch thick it will diminish the efficiency to 7-8 of that which will obtain when the surfaces are perfectly clean. From this point on, if the crust thickens, the diminished efficiency will be proportional to the square of the thickness of the scale.

It has been repeatedly stated by the most competent authorities that scale, once it is deposited, cannot be removed excepting by scraping. Whether it can or not will not alter the fact that radiators, as they are made, cannot be mechanically gone over with a scraper. If, in the attempt to remove scale by means of chemicals, the surfaces are attacked, the damage, as measured in dollars, will be equal to the cost of a new radiator sooner or later.

Under the circumstances, if a radiator is not large enough to do the work without evaporating water, it is a moral certainty that the time will arrive when the motor will fail to do its best work, even if it does not indicate trouble of a more serious nature. If the radiator is large enough to accomplish the cooling purpose without boiling the water, the question of eliminating the foreign matter will not have to be coped with, but if the reverse is true, the one safe measure lies in removing the foreign matter before the water is placed in the radiator.

The temperature of precipitation, as shown in the table of precipitations, will obtain under conditions of a heated radiator to a degree high enough to induce serious trouble, and, the vegetable matter, which is a crust former of no mean ability, will precipitate in the presence of iron at any temperature.

One very good way to filter water is to allow it to settle in a barrel in which a quantity of pig iron is placed; the foreign matter will adhere to the pig iron, and, from time to time the same may be removed and washed. This process will not eliminate the salts of sodium, calcium and magnesium—they must be treated under proper conditions of temperature in the presence of substances given in the table of elimination of impurities.

Distilled water is the one right answer; it will be so free from all scaling substances that no further trouble needs be anticipated, and the cost of the same is far less than the repair account which will fall to the lot of the owner who is keeping company with a car which is fitted out with a steaming radiator.

ELECTROLYTIC ACTION IS MUCH TO BE FEARED

Any metallic salts, or acidity, in the presence of any two or more metals submerged in water will constitute an electric couple, and local action will follow. The metals, differing from each other, will form the poles of a battery and the water, charged with salts or acid, will compose the electrolyte. It will be impossible to state with any degree of certainty as to the extent of the electrolytic action which will be set up in a radiator when acid or salts is present, due to lack of data of the degrees of concentration of the electrolyte, and the nature of the chemicals.

Electrolytic metallurgy, which is the heading under which all such matters are dealt with, consists of the very process by which metals are dissolved, deposited, and separated under the electrolytic action which is sure to follow if two or more differing metals are submerged in an electrolyte.

It is for this reason that calcium chloride, if it is employed in solution to prevent freezing, is so very dangerous; this danger is particularly noticeable when the chloride is of the brand designated as "commercial"; this form of the material is sufficiently impure to hasten the electrolytic action. Heat, as it is bound to be a condition in radiator work, hastens the electrolytic action; the extent of this action being intensified as the temperature increases up to a certain point.

Sodium chloride (common salt) would be an excellent material to add to water for the purpose of preventing freezing were it not for the electrolytic action which would surely follow its use. Grease, on the other hand, is not good for the purpose. The grease will coat over all the surfaces of the radiating system and retard the transfer of heat just as a crust of foreign substance will. The grease coat, if it forms, will pick up foreign matter and form a hard crust which is a very perfect insulator of heat, which is exactly what is not wanted in a cooling system.

Mineral oil, after it has been filtered a number of times by passing it through fuller's earth, if it is very lacking in viscosity, will do cooling work, but, unfortunately, it is necessary to design the radiator in view of the use of this cooling medium. A considerably greater area of cooling surface is required than when water is used.

Alcohol in water will do very well for a freezing mixture, especially if the alcohol is pure, and the water is distilled. About one-quarter of the whole solution should be alcohol. Care must be exercised to maintain the strength of the solution; the alcohol will evaporate more rapidly than the water; it is not a very good solution to use in a steaming system. As a matter of fact there seems to be no good way of keeping entirely out of trouble if the radiator is not large enough for the work which will have to be done, and, when all is said, it is probably cheaper to purchase a new and better radiator in a case of this sort.

Glycerine, in the proportion of 1:4, the major portion being water, is much used and it seems to be very good excepting that it becomes foul after a time and a new supply must then be used; it is rather high priced, and it attacks the hose connections which are placed in the piping system to form flexible joints.

In winter (cold) weather, if autoists do not care to risk the use of cooling solutions with which they have no experience, it is necessary for them to empty the water system out every time the automobile is stopped if the time of interruption is more than that which will allow of the water being cooled off. The very fact that a radiator is efficient is the reason why it will ice up in a little while.

CARBON FORMATIONS IN CYLINDERS MAKE TROUBLE

It is not in the cooling system alone that trouble is to be expected from incrustation. If a coating forms over the combustion surfaces, it will have just the same effect as if it grows on the surfaces of the radiator. This crust, while it is attributed to free carbon in the lubricating oil, may come out of the gasoline, due to the use of an excess. It may also be due to silicon and other foreign matter, which will be sucked in through the air intakes of the carbureter. The inner surfaces of the combustion chamber, unless they are kept free from incrustation, will materially reduce the good performance of a motor, nor is the usual theory in relation to this action in full accord with the facts.

Knocking will follow if the pressure wave increases at a very rapid rate to a very high point, and this condition will be induced if a coat of carbon or other heat retarding substances is formed over the internal surfaces of the cylinders. The amount of the formation will not have to be so great as to increase the compression as is so generally believed, but just enough to prevent the heat to pass to the water jacket, at the time when the excess will induce a sudden increase in the pressure wave.

Carbon will coke out of the gasoline if the same is in excess and the heat is applied at such a rapid rate, at the high temperature required, to break down the gasoline structure; all the carbon in the fuel, under these conditions, which does not pick up oxygen, will coke out. The excess gasoline will not find oxygen sufficient to produce carbonic acid, carbonic oxide, or water, and, all that can be formed, under such conditions, will be coke.

This trouble is mostly charged up to lubricating oil, but it is now fairly well established that much of it is caused by the presence of an excess of gasoline, or, what amounts to the same thing from this point of view, lack of air. It is to be seen, considering this idea, that the questions of the carbureter are included in a sense, and in coping with the problems of the cooling system it is necessary to be sure that the fuel relation is within manageable bounds. For that matter, ignition troubles must be eliminated when the radiator question is being investigated.

There is nothing in this article which should be very consoling to the autoist who has picked the wrong cooling system, nor is there any statement to the effect that a motor will not run if the radiator is not big enough for the purpose, but there are strong grounds for suspecting that it is economy in the long run to purchase a sufficiently large radiator to do the work without steaming. It is even a question if there is much danger of being able to use a radiator which will be too large for the purpose—room is much restricted in automobiles. Here, as in most cases, it is better to err on the right side.

Causes of Incrustation in Radiators

Deposition of:
(A) Lime soap.
(B) Iron soap.
(C) Grease saponification with other substances.
(D) Sulphate of lime.
(E) Carbonate of magnesium.
(F) Carbonate of magnesia.
(G) Other magnesium salts.
(H) Suspended vegetable matter.

Note.—If the radiator is not of a good design, it is likely that all these troubles will be experienced the sooner; fins, projections, and places of lodgement are bound to attract precipitations, and, if the location of the accumulations is that which will stop circulation, trouble must follow.

Preventives of Incrustation in Radiators

(A) The use of distilled water.
(B) By filtering and boiling the water.
(C) By maintaining a low temperature of the water.
(D) Removal of carbonic acid from water and settling.
(E) By chemical treatment of the water.
(F) By removing the water from the radiator frequently.
(G) By blowing out the radiator with steam.
(H) By the use of some chemical medium besides water.

Note.—In some geographical localities the troubles which are due to precipitations and the resultant incrustation, are very noticeable as compared with others, and it is for this reason that complaints from some autoists are not verified by others.

Electrolytic Action Used in the Arts

(A) In electrotyping.
(B) Electroplating.
(C) Electrolytic reduction of metals.
(D) Electrolytic refining of metals.
(E) As a destructive process in steam boilers.
(F) As a destructive process in automobile radiators.

Note.—If a process is so pronounced that it may be used in the arts to advantage, this is proof of the fact that the same process, if it is used under damaging conditions, will be rapid, and, success, if it is to attend the plan demands that this action be eliminated entirely.

The way to avoid such action is to maintain a pure state of the cooling medium—chemically pure if possible.

GOOD ROADS, CUSHION TIRES

Editor THE AUTOMOBILE:

[2,175]—I wish to ask your advice as to tire trouble. I have a Pope-Tribune, one seat single-cylinder car, with wheels 28 by 2 1-2. Now, I live five miles from town on a good smooth pike, and when my wife and I ride in it, we go for pleasure and not for a speed record. I do not care to go more than 10 miles per hour, but I want to go with a certainty of no tire trouble, as I am too old for that kind of trouble or monkeying. Could I put on a good solid tire or cushion tire and get good results with it at a moderate speed, and at about the same expense as I am now having with pneumatics, or would it shake up my engine too much? It is a vertical engine, well braced and fastened to the frame. Last year my car was the second in the county, now there are no less than thirteen.

Cynthiana, Ky. J. P. HODSON.

At the very modest speed, to which this gentleman is partial, solid tires would do very well, the slow speed reducing the bouncing and bumping to a minimum quantity, if not to a negligible amount. As was pointed out in last week's paper, the influence of speed upon the stresses and strains of the car is just twice that due to weight. At this very low speed, ten miles, the factor, V^2, becomes very small. The change to solids would be a safe one under these circumstances.

TIMING OF THE INLET VALVE

Editor THE AUTOMOBILE:

[2,176]—Will you please answer the following in your "Letters Answered and Discussed": At what time should the intake of a two-cylinder engine open after the piston leaves dead center? That is, we want to know at what time it should begin to open.

Roachdale, Ind. LOCKRIDGE & ASHBY.

If the exhaust valves of your engine are working properly, you can time the inlet valves from them; the inlets should open just as soon as the exhausts are firmly closed. In any case, the timing of the inlets must depend on that of the exhausts, as they must not open before the exhausts have closed. If you are sure of the exhaust, then, you will need no further information. The timing for a two-cylinder motor is no different from that of any other motor, except in the fine points raised by the different speed conditions under which the engines are run.

Customary practice in regard to opening the inlet valve varies between 10 and 20 degrees travel of the crank after the dead center, depending, as stated above, on the closing of the exhaust valve. Practice also varies as to whether the inlet valve should open immediately after the closing of the exhaust, or whether there should be more or less of an interval between.

If your exhaust timing is wrong, too, the best thing for you to do is to write to the makers and find out how it was intended to be. Most modern motors have the timing marked on the flywheel. The inlet valve should hold open about as much after the lower as it delays opening after the upper center.

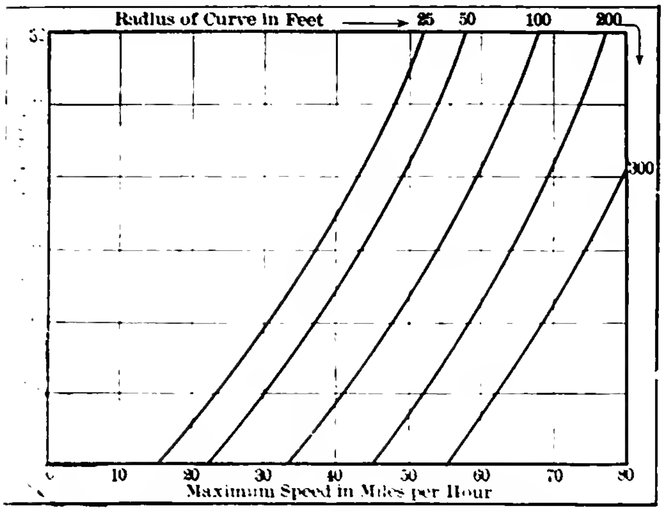

Chart of Relation of Speed to Curvature

LETTERS INTERESTING

HEATING GARAGES BY STOVES

Editor THE AUTOMOBILE:

[2,177]—Referring to the inquiry number 2,139, appearing in the January twentieth issue of "The Automobile," in which you speak of some simple heating contrivance to be used in heating a barn, do you think such a stove safe for a private garage owner of a small barn? Can such a one be used with perfect safety and no fear of explosion? I keep my tank in the car filled with gasoline, and often in the mornings, when opening the garage doors, I detect a perceptible odor of gasoline, making me fearful of installing a stove.

New York City. E. N. W.

If you keep gasoline other than that in the tank of your car in the garage it certainly would be dangerous to keep a stove there for heating purposes. If not, however, the tank in the car should not entail any danger, and if, as is stated above, a perceptible smell of fuel is noticed every morning, without any fuel being spilled, it must be that there is a leak in the present tank. Look to this point very carefully, as it not only means a high consumption, and consequently expensive fuel bill, but some fine day your car, garage and other belongings will suddenly start in to emulate the Wright brothers and other human birds. This sort of thing makes people peevish, so it is well to provide against it.

BANKING, CURVES AND SPEEDS

Editor THE AUTOMOBILE:

[2,178]—I have been somewhat confused with the various references to the relation of the curvature and banking of racing tracks to the possible speeds. Will you please explain this in some detail, through your column of "Letters" and help out a number of interested subscribers?

New Rochelle, N. Y. INTERESTED SUBSCRIBER.

To give the exact relation of these three quantities would entail much mathematics, but the crux of the situation is given in the appended curve, which shows this interrelation. The vertical quantities or ordinates are the inclination of the road or track to a horizontal in degrees. At the top the abcissæ are the feet radius of the curve, while at the bottom the abcissæ are speeds in miles per hour. It is here seen that the three quantities are so closely related that it is impossible to change any one without altering the others. Thus, to obtain a speed of 50 miles per hour on a curve of 100 feet radius, follow the curve from 100 radius down to the intersection with the vertical line representing the speed desired (50 miles). Thence proceed across the horizontal line to the left-hand scale to find the banking necessary to allow this speed without overturning, in this case 13 degrees. Similarly, knowing the banking and radius, the possible speed may be found as follows: Suppose there is a radius of 200 feet and that the banking is 15 degrees. Then, proceed from the 15-degree line at the left across to the intersection with the curve for 200 feet radius, drop down vertically to the base line from this intersection and find the desired speed, 64 miles per hour. Similarly given any two quantities the third can be found using this curve, or given but one, an assumption may be made for a second, and the third thus found, approximately. This may be repeated, using higher and lower value for the assumption, until the desired combination is found.

The banking of automobile tracks, so-called "motordromes," is rarely sufficient. A few extra inches of dirt on the outside allows the promoters to claim that it is "scientifically banked."

ANSWERED AND DISCUSSED

STUDENTS' SIDE OF EMPLOYMENT

Editor THE AUTOMOBILE:

[2,179]—I note in one of the back numbers of "The Automobile" of which I am now a constant reader, on page 1067 of Dec. 16, 1909, Robert Jardine, superintendent of the Royal Tourist Car Company's plant at Cleveland, states that the greatest need of the automobile industry is a supply of intelligent machinists, and also says that all around men are badly needed. Again he says: "The trouble seems to be that young men who have passed through high school will not enter a plant as apprentices." He may be right when he says they will not enter, but there's a reason. It is not because they are not interested, for where I attended high school last year in Connecticut, there were some who were studying automobiles nights. I was one of the interested ones. One of our number obtained a position in a New England factory, and the agreement was this: He must work six weeks for absolutely nothing, after which he would receive a dollar a day. Take a lad living away from home, how can he do it? It appears that the manufacturers want the lads and the lads want the positions (and I am one of those lads) but the trouble is that these lads cannot afford to start. If any real opportunity arrives I would like to obtain one of these positions myself, and would gladly receive any direct communications from the manufacturers. I have spoken in behalf of the high school student and its graduates.

Greenfield, Mass. CLINTON J. CONVERSE.

MAGNETO AND OTHER DIAGRAMS

Editor THE AUTOMOBILE:

[2,180]—Will you please explain through the excellent and very enjoyable "Letters Interesting, Answered and Discussed" what is the difference between the various electrical windings, that is, how does the magneto winding differ from dynamo winding. Also, what is the difference between shunt, series, compound, and other windings, often spoken of? Please illustrate by diagrams.

Buffalo, N. Y. R. E. P.

Magneto winding differs from other winding in that the former is wound to produce a spark at a given time when the circuit is ruptured, which is done frequently. The latter, on the other hand, considering dynamos, motors and the like, are wound so as never to produce sparks, and the current output is a steady discharge or continuous input, with no interruptions.

In the sketch below this is depicted graphically, the magneto winding being shown first; separately excited field, second; series winding, third, and in the lower row, in order, shunt, compound, and differential windings. Each one of these has a different use requiring the difference in the winding.

In the first, separately excited, it is seen that the current which passes through the field is supplied from an outside source, the two wires leading off at the side indicating this. In the second, series winding, it is seen that one of the leads from the rotating armature is wound around and through the field, while the other armature lead is direct. Shunt winding consists of a winding from one of the armature leads, around through the field, then back onto the other armature lead; that is, it forms a loop around the armature windings. Compound winding is, as will be seen in the figure, a combination of the shunt and series windings, its name indicating that it is a compounding of some other methods. Lastly, differential winding is shown. In this an armature lead is utilized for the lower layer of the field, being wound upon itself for the second layer of the field. It forms a shunt upon the armature circuit, this having been previously described as nothing more than a loop. Magnetos, properly speaking, have no field winding at all.

CHANCES FOR YOUNG DRIVERS

Editor THE AUTOMOBILE:

[2,181]—Would you kindly answer the following questions: (1) Are there any automobile companies looking for men to drive cars?

(2) Could a young man having one season's experience driving and taking care of a car, and having no bad habits, easily obtain a position as a chauffeur? Are these young men much in demand?

(3) In what States do chauffeurs require a separate license?

Anita, Ia. A SUBSCRIBER.

All of the automobile companies are now looking for men of experience, particularly in Detroit, where there is said to be a famine of men. The Chamber of Commerce of that city is said to have imported some 16,000 men in the past year from other cities, but still there is not enough to go around.

Yes, a young man such as is described could easily obtain a position as a chauffeur, and, as we understand it, such drivers are in demand at all times.

Nearly every State in the Union requires a license, but in a great many of the States the license is taken out for the car, no matter who drives. In such States, of which we are now unable to give you a list, the chauffeur would not need a license.

METHODS OF STARTING THE CAR

Editor THE AUTOMOBILE:

[2,182]—In your issue of January 20, 1910, E. J. Montgomery, of Clinton, Mo., complains of difficulty in starting his motor in zero weather.

Your solution of the difficulty was to install a heating plant which is no doubt the very best advice under the circumstances.

My car is housed in a cold stable, and although generally speaking, our winter has been very mild so far, we have had to turn on the "juice."

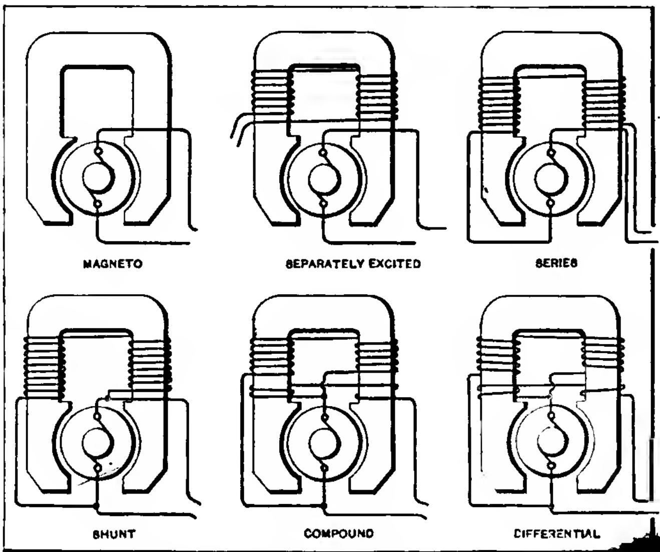
While I am eating breakfast the lamp warms up enough to make cranking comparatively easy, so that by using a little ether on a piece of cloth stuffed in the air intake of the carburetor "she is off" after being turned over a couple of times.

The idea of using ether to help start was given in the columns of your paper some time ago, and I have found it very helpful a few mornings when the temperature was from 6 to 10 degrees below.

Now when I get up in the morning and find it so very cold I go out in the garage and take a thirty-two candlepower electric lamp attached to a flexible cord, and lifting the hood put the lamp inside next to the carburetor and crankcase. Then I put the hood down and cover the radiator and hood all over with my large fur robe, and I hope the above suggestions may prove helpful to your correspondent and possibly others.

Concord, N. H. CHARLES H. COOK, JR.

This is a very good method, but we should think it very expensive. Not only is electricity expensive, but the very large lamp used consumes much current. The whole should put the electric light method of warming garages out of the question for the little fellow, who must perforce economize on garage charges.



Wiring Diagrams of Magnetos and Dynamos

Clutch Repairs and Maintenance

By Oliver Light

CLUTCHES are of many forms, in fact, one might say that there are as many clutches as there are automobiles. The various constructions may be divided into groups, each one varying from the others only in the matter of minor detail, according to the individual preferences of the designer responsible for the car to which it is applied. The forms to be considered as typical of standard practice are the cone, three-plate, expanding band, and multiple disc clutching devices.

Troubles evidenced in one form may be found in others, though as a rule the same conditions cannot apply to those of different types. The cone and expanding-band forms will require about the same degree of care and attention, and will be subject to the same derangements, while the multiple-disc construction will deteriorate in an entirely different manner.

Perhaps the most common form is the cone, which consists of male and female members and a spring to maintain contact between them. The female portion is often formed directly in the flywheel rim, while the other member is a casting or stamping faced with some friction material. Next in order of importance are the multiple-disc clutches, designed with a view of eliminating some of the troubles present with other forms, but which at the same time introduce others in their application and operation. The expanding band and three-plate share the honors as to popularity, but as they are fitted to cars of reputable make, demand some consideration, though one rarely sees a clutch of the external constricting-band type.

Speaking as a repairman who has had experience with each and every form, and is able to expose their various weaknesses, at the same time suggesting differences in construction which might be of use to any skilful designer, willing to use them, but who also can see disadvantages which are not so evident to their creators, the writer will analyze some of the successful forms and expose their weaknesses, at the same time suggesting methods of repairing them which have proven practical.

Failure to Engage Properly, the Biggest Trouble—The troubles which most often develop are failure to engage properly, which may be either slipping or failure to transmit power, or harsh and too rapid engagement, or imperfect release. Those clutches faced with frictional material will deteriorate because of loss of this facing through natural wear, while other forms will prove unsatisfactory in operation due to other conditions. In overhauling a car, even if the clutch mechanism has not given trouble it will be well to take it apart and carefully examine the components to detect wear that may cause trouble in time, and which can best be prevented by proper restoration.

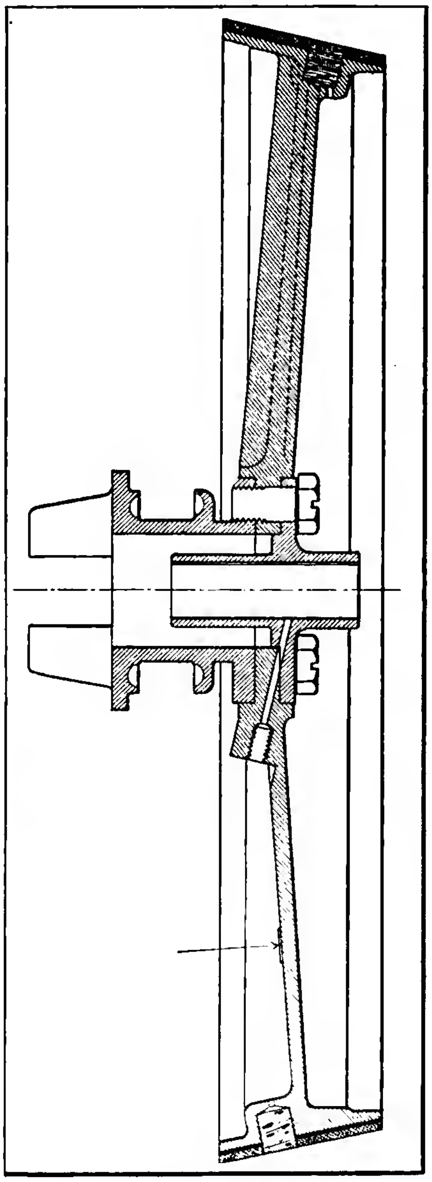


Fig. 1—Illustrating a leather-faced cone clutch with cork inserts

Deterioration, Considering Cone Clutches—If a clutch of the cone type has been properly designed the only points where deterioration will be manifest will be at the leather facing and at the bearing surfaces of the male member where it revolves on the shaft. The leather may have become hard or charred because of slipping that has caused the facing to heat. The spring that holds the parts into engagement may be broken or weakened and this will be sufficient to cause trouble even if the facing is in perfect condition.

Any wear at the bearings will cause the cone to sag when the spring pressure is released and will cause dragging as the parts are still in partial contact. If the leather wears so that the rivets holding it to the cone bear against the frictional surface of the other member, the clutch will slip and the surface may become cut or roughened by the abrading action of unlubricated metals in contact. Two of the most common clutch troubles are harsh engagement as one extreme and slipping as the other, and if the facing appears to be in the proper condition, that is, not charred or worn too much, it will be a comparatively easy matter to make a remedy. Slipping is caused by the frictional material becoming coated with lubricant, reducing the coefficient of friction to a low point.

Under these circumstances, the pressure of the spring may not be sufficient to maintain the parts in proper contact. This surplus of oil may be observed by various substances, the most efficient being fuller's earth, well rubbed into the surface. If the clutch cone is in place this material may be inserted with a small bellows such as used for injecting insect powder in inaccessible places.

It is sometimes possible to place enough of this material on a card or piece of paper to apply it to the surface through the space left between the cone and the outer member when the former has been fully disengaged. Borax has been used with good results but never use rosin, which is often advised by the armchair expert, for while it may work very satisfactory for a time, should the clutch slip it will melt, and rosin in liquid form acts as a lubricant, and the effect is worse than before it was applied, acting the same as though the leather had been oiled.

Causes of Harsh Engagement—If a clutch of the leather-faced type is engaging too harshly it is due generally to the leather becoming hard and dry, and not yielding when brought into frictional contact with the co-acting metal surface. To secure gradual acceleration the clutch leather should be soft, that is, it should

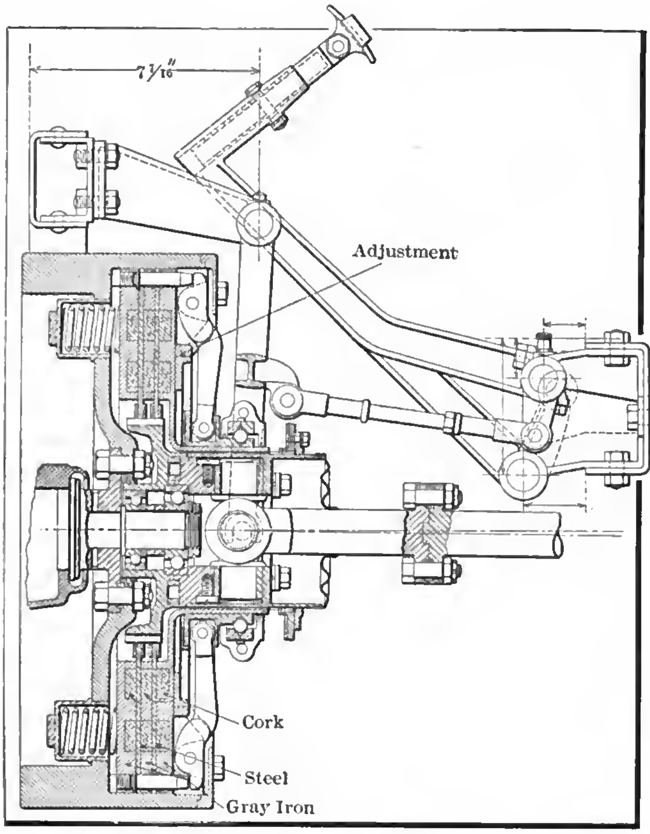

Fig. 2—A five-plate clutch of steel and iron, with cork inserts in the iron plates

have sufficient elasticity to yield slightly before becoming fully engaged. If the leather facing is not charred or worn unduly, being merely hard, it may be restored by rubbing a small amount of either neatsfoot or castor oil into it, which will soften it and make it more elastic if hard because of the natural oils drying out.

Kerosene oil may be used in a pinch, and the writer has often had occasion to use this material on the road when the others were not available, taking this from the lamps. Never allow a clutch to slip, as a slightly harsh member is to be preferred to one that will not drive properly. If slipping is evidenced and allowed to continue, the frictional facing of the male member, especially if of leather, will harden or the surface become glazed over, or so heated that charring and resulting destruction will follow and involve more or less costly repairs.

In the event of the surface becoming glazed, it can be roughened up with a piece of coarse sandpaper or a rasp. Among the good features of kerosene may be mentioned that it acts satisfactorily as a clutch-leather dressing, as it has very little lubricating qualities and while it will keep the leather pliable it will not increase the coefficient of friction existing between the surfaces as will either of the lubricants or heavier oils mentioned previously.

This liquid has the additional advantage of penetrating the surface quicker than the heavier oils, and is not so liable to gum or hold other oil. Many authorities advise the motorist to clean out the clutch leather with gasoline in event of slipping, but this practice cannot be too strongly deprecated. This treatment will harden the leather, and will induce the opposite condition to slipping, which is equally undesirable. If the slipping is due to lubricant, absorb it with fuller's earth.

How to Cure Slipping Due to Weak Springs—Slipping, due to weakening of the springs, may be remedied by the substitution of members of greater strength or by increasing the degree of tension of the weak spring if some method of compensation or adjustment is provided. Where the leather or other frictional facing is worn too much, the member may engage so deeply as to bottom against the flywheel, in which event slipping is inevitable. The only remedy is fitting a new leather, and while mechanical skill is required to properly fit a new facing, it is not difficult or beyond the ability of the average individual.

If the old leather is not broken or torn it may be removed intact and used as a pattern to cut the new one by, though when it is necessary to reline the cone, the old leather is often removed in fragments. Should this be the case the correct shape for the new facing may be determined by cutting a pattern from stiff wrapping paper, or a simple process of laying out will save much time and stock in cutting the material to the proper size before fitting.

An old dodge often used by the experienced repairman is to take a large sheet of paper and lay out the clutch-cone section to exact size, being sure that the faces are at proper angle and a proper distance from the center line. Draw a long line through the center of the hub and continue the angle of the cone by straight lines meeting on this center line.

Use the point thus obtained as a center and the distances from the outer edge of the cone to this point as one radius and from the inner edge of the cone to the point as the other radius, then describe two arcs which will be of concentric circles and will be as far apart as the width of the cone along the angular face. The circumference of the cone at both the outer and inner edges is then obtained, and one-half thus ruled off on the arcs described at either side of the central line drawn through the clutch hub.

The amount ruled off the larger arc must equal a little more than the larger circumference of the cone, while that ruled on the inner arc must equal a little more than the smaller circumference. This is advisable because it is well to make the strip a little longer and allow for fitting. The pattern thus obtained my be used to cut the new leather.

Opinions Differ as to Oiling Leather—Before riveting in place the leather should be made as pliable as possible with oil, though there exists some difference of opinion among repairmen regarding this practice. Some advocate soaking the leather in water and applying it wet, that when it dries it will shrink closer to the cone, while others apply it dry and oil it after it is in

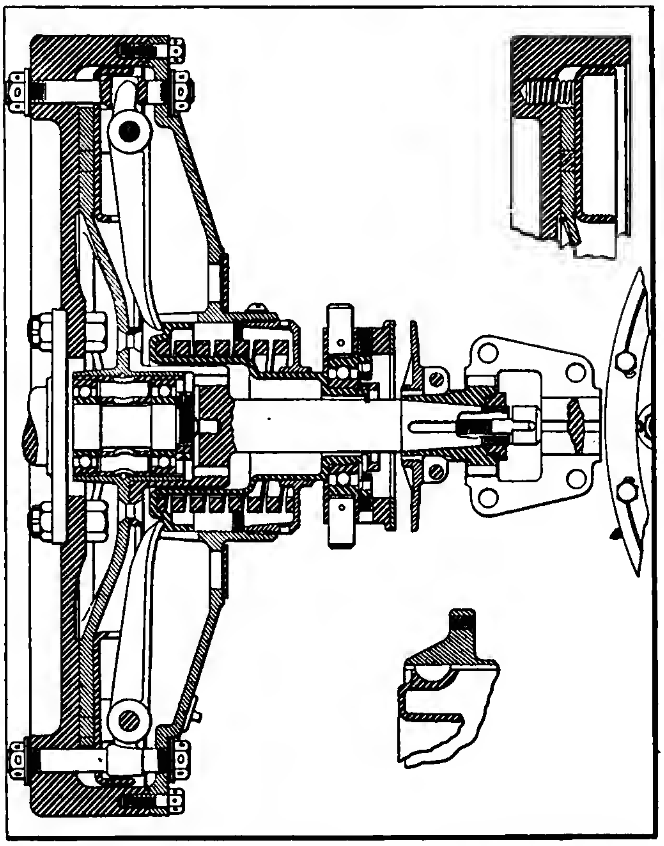

Fig. 3—High power three-disc clutch of unusual diameter and very simple

place. The writer does not favor wetting the leather, as after it is in place and shrinks it often pulls away from the rivets and when applied dry and oiled after the cone has been surfaced it will be liable to bunch between the rivets.

When the leather is oiled before application with either neatsfoot, castor oil or even kerosene, it is soft, pliable and elastic and if properly fitted there will be no trouble in the leather either becoming too loose or so closely engaged around the cone that it may burst from its fastenings.

The actual process of fitting will vary with the ideas of the mechanic doing the work, though as good a method as any consists of placing the leather in position at one end, holding it in position by small clamps. The holes may be then drilled and the leather riveted in place, care being taken that the rivet holes have a countersink deep enough so that the head of the rivet will come well below the surface of the leather.

After one end is firmly secured, the leather is pulled around the cone to the next point of fastening, the facing being kept in a taut condition by a clamp while the holes are being drilled for the second set of rivets. This operation is repeated from one point to the other all around the circumference of the cone. Fitting the facing in this manner insures that it will hug the cone closely instead of bunching up between the rivets as is the case when all the holes are drilled into the leather at the same time.

When the facing is applied the cone should be swung in a lathe and the surface of the leather trued by taking a light cut of its surface with a cutting tool, or the high spots may be rubbed off by hand with coarse sandpaper, glass or a coarse file. The best material for cone facing is good oaktanned leather, such as used for belting, though hemlocktanned has often been used. The writer has found that the former material possesses most of the qualities of elasticity, durability, and frictional adhesion required.

Sometimes a clutch will engage harshly and if the leather face seems to be in good condition, it may be well to see if the small spring members, often placed under the leather facing, are in proper condition and that the surface is raised at spots, as it should be to secure gradual engagement.

Old Clutches May Be Improved, Using Surface Springs—Many cars of old pattern do not have these springs and the clutch action may be improved by fitting appliances of this character. The small flat springs inserted directly under the leather surface are not satisfactory in general application, the preferred method being to use small plungers or member that will depress flush with the surface of the cone when the pressure is applied. The small flat springs under the surface are liable to break or lose their elasticity after continued use.

There has been considerable interest in the application of cork inserts in clutch members to eliminate harshness, as well as increasing the power transmission qualities without increasing the dimensions of the friction surface. They are of obvious value and the writer does not hesitate to commend their use wherever practical. There are instances where this material has worn, however, and the good qualities lost. In such an event replacement is the only remedy and as new corks are inexpensive, there is not much excuse for failure to apply them at once.

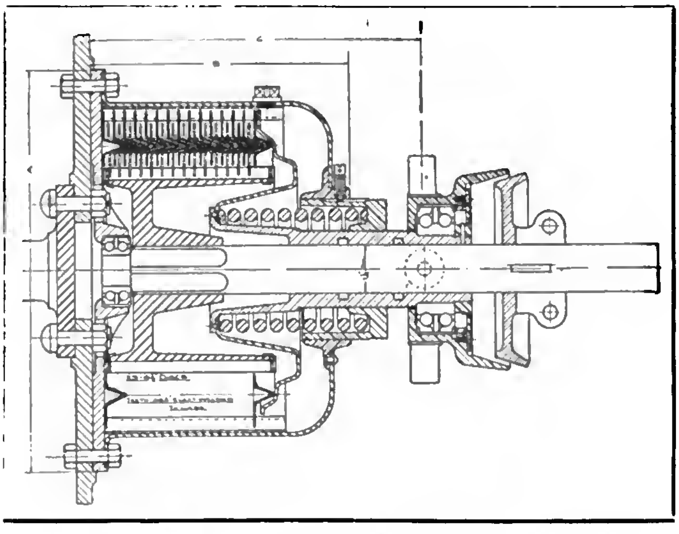

Fig. 4—Multiple disc clutch of the Hele-Shaw type, readily accessible

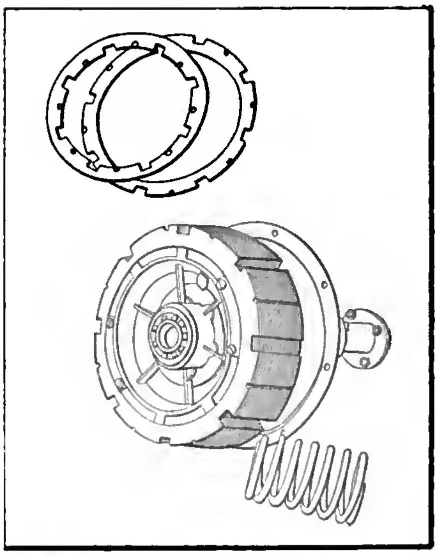

Fig. 5—Another multiple disc clutch but of the flat plate type

Some Common Causes of "Spinning"—The writer knows of no more annoying condition than continued rotation of the clutch parts when the spring tension is released, this being known as spinning. This may be due to natural causes, such as inertia due to the use of clutch members of considerable weight and diameter, but it is often caused by derangement of the parts.

If the bearing in which the transmission shaft telescopes runs dry, or that on which the cone revolves when disengaged is not properly oiled or seizes, the male member will continue to spin, even when disengaged. When the clutch is dismembered it will be well to examine the shaft for any roughness, see that the oil holes are clean and allow the lubricant to reach the bearing parts.

A sudden road strain often produces enough distortion of the frame to cause a slight disalignment between the members of the clutch, especially if joined to the gear box by a mere telescopic or sliding joint which does not permit of universal action. Again, if the bearing or bushing in the cone hub is worn unduly the member may sag and remain in contact with the female portion. A ball-thrust bearing may become tightly bound because of a broken ball or particles of foreign matter which will cause the motion of the engine to be transmitted to the male member by the clutch spring. If the trouble is produced by natural causes it is not difficult to fit small brakes which will be interacting with the clutch pedal and act as a retarding medium to resist continued rotation due to inertia.

For relining the cone the suggestions given will apply as well to any other form of clutch which uses leather as a frictional material. An example of clutches of this class are the internal-band clutch, which has been fitted to a number of prominent cars in the past. In most cases, the leather facing wears more rapidly than on the cone and is more susceptible to the effects of lubricant on the surface.

A feature of these is that means are provided for compensating for wear of the frictional material, though adjustments must be made with care or they will drag. In event of slipping because of surplus oil, the same attention should be given as in the cone. As is true of the form previously discussed, harsh engagement is due to the leather surface being hard, and slipping will cause heating and deterioration of the drum facing.

If necessary to reline the steel band, it is removed from the aluminum cylinder and the leather applied in the conventional manner, and as the surface is parallel with the shaft there should be no difficulty in fitting a new strip when needed. After this is riveted to the band the latter is replaced on the drum and the leverage coupled so that the steel band will hug the outer periphery, and the entire assembly is then placed in a lathe on

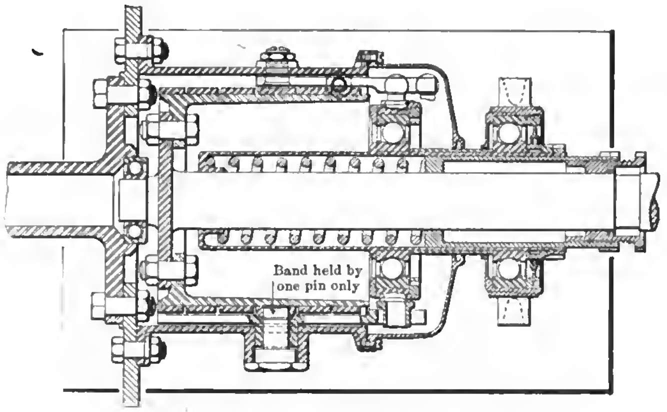

Fig. 6—Wrapping band clutch on a hardened steel drum with means for take-up

centers and the outer surface of the leather is trued and smoothed. Special care should be taken in applying the rivets, as in the form previously considered. The leather should be pliable and soft.

Multiple Disc Much Used Nowadays—Many modern cars are fitted with multiple-disc clutches, the plates in some cases being entirely of saw-blade steel; in others of a combination of different metals, such as steel to bronze, etc. It is well to take a construction of this kind apart and carefully examine the condition of the plates. These should be perfectly smooth and clean and the co-acting surfaces free from roughness, cuts or scratches. A most common cause of slipping with this form is caused by distortion of the thin plates because of becoming heated by continual slipping, which may be caused by abuse of the driver or to weakness of the spring maintaining contact between the parts.

Too harsh engagement is caused by lack of lubricant, excessive spring pressure, presence of carbon or roughness of the surfaces. Spinning is promoted by seizing between the plates due to either the burnt or gummed lubricant between them, the weakening of the small springs designed to hold the plates apart when the spring pressure is released, or the attraction or adhesion of the plates to each other because of too thick oil between them.

In many cases, distortion of the plates is caused by internal stresses in the material because of the rolling, which can only be removed by annealing the discs and straightening them on a surface plate. If on examination it is found that the interior of the clutch is blackened, there is not oil present and the plates have seized because of lack of lubricant, the clutch should be disassembled, the plates separated and the scored or cut surfaces smoothed with a surface grinder or by hand, using fine emery cloth.

More Care in Selecting Oil for Multiple Disc—It is imperative that only a good grade of medium or light cylinder oil be used in any multiple-disc clutch, as the inferior oils or those of too great viscosity will gum and carbonize because of the heat, and in either case they are valueless. If a multiple flat-plate clutch drags, one may suspect the use of unsuitable oil. In types where the pressure is maintained by a spring acting against a ball-thrust bearing it is imperative that this component be maintained in condition and well oiled at all times. In many cases, faulty clutch action has been due to conditions existing outside of the clutch, such as wear at the various points of the operating mechanism and defective adjustment of the linkage.

As the type of control differs with every car it is not possible to suggest other than general instructions. Many cases of failure of clutch to release have been traced to poor adjustment of the interlocking levers and rods, for instance, a worn shifting collar or yoke often hinders disengagement, as the clutch pedal may be fully depressed without materially releasing the spring pressure maintaining the members in contact.

Small pins are often worn to half their diameter and the holes in which they are designed to fit are worn oval, considerable play being evident. If this exists at several points it may amount to considerable and the lost motion not only produces rattle, but makes proper operation of the clutching mechanism impossible.

Failure of clutches to engage properly has been caused by faulty adjustment of the interlocking leverage, where the emergency brake lever acts upon the clutch, disengaging it when it is applied. Often an incompetent person will compensate for wear by shortening or lengthening the brake-operating rods, and this may have the effect of throwing out the clutch mechanism slightly, and an unexplainable slipping will be caused because the interlocking connection holds the clutch partly out and does not permit of the full spring pressure being exerted.

This is a small but important point, which amateur drivers should bear in mind when having clutch trouble, which seems to need an explanation, or in cases of inexplainable trouble which cannot be traced to any other source. Remember this point.

Notes on Alloy Steels Used in Automobiles

WONDERFUL stimulus has been given the metallurgy of special steels by the demands of automobile construction and constructors. The extent of this demand, and the ready response of the steel makers, together with some notes of the resulting product, were all given space in an English article on this subject which appeared some months ago. This is given herewith, or, rather, extracts from it are given, in the hope of being useful to some members of the automobile profession on this side.

The heavy moral responsibility which rests upon both the maker and user of alloy steels and the tremendous duty expected of these materials of construction—lightness without sacrifice of toughness or strength—tend to make the requirements of the motor trade most exacting. It is inconceivable to the mind how any firm can conscientiously put out a car and not know intimately the materials used in every essential part. Yet such is frequently the case. For example, nickel steel is asked for. Now, nickel steel is a delightfully variable and uncertain quantity as ordinarily made. There are of nickel steels at least fifty-seven varieties, and the user should know what kind of nickel steel goes into his gears and who makes the steel, as well as the gears.

Dr. Guillet, the distinguished French metallurgist, has pointed out that the constitution and mechanical properties of nickel steel depend essentially upon the sum of the carbon and nickel. From past experiences should be added to this sum the manganese. One hears continually in the trade nickel steel referred to solely by its percentage of nickel. Such expressions possess no real significance as a measure of quality or adaptability for various purposes. It is the skilful blending of the elements—carbon, nickel and manganese—that counts. The successful accomplishment of this is a fine art.

Almost as bad as not specifying at all is the tendency upon the part of many buyers to tell the maker how he ought to make his steel; to specify chemical analyses and physical tests which are a misfit, and to make the wording of the specification a place to show how much they know, as well as to display a mental attitude of favor or antagonism to any of the parties affected by it.

Without attempting any scientific classification of alloy steel, or enumerating all types that have been used at home and abroad, the principal types will be described as briefly as possible, utilizing only those which have been used freely in the automobile business in the last two or three years.

ANALYSIS OF NICKEL STEEL

Nickel steel is perhaps the most generally used of the alloy steels. The analysis usually desired, but not always attained, is: Carbon, 0.20 to 0.25; nickel, 3.50; manganese, 0.60 to 0.90; sulphur and phosphorous, not over 0.04. With the proportions of carbon and nickel stated, manganese ought never to exceed the limits mentioned. A slightly lower carbon is sometimes used for case-hardened purposes, and a higher carbon is much used for crankshafts. With higher carbon I should prefer lower manganese. A small quantity of 5 per cent nickel steel is used in about the same carbons. With reasonable care, nickel steel can be made uniform, physically sound, and free cutting.

It has remarkably good mechanical qualities when subjected to suitable heat treatment, and is an excellent steel for case-hardening.

In machining qualities it is usually accorded first place among the alloy steels. When extraordinary care is used in its manufacture, and it is not made in too large heats or ingots, and when piping and segregating are avoided by confining the finished product to that produced from the bottom two-thirds of the ingot, we have an admirable product for many purposes.

CHROME-VANADIUM STEEL ATTRACTS

Chrome-vanadium steel in a profusion of types has of late attracted the attention of automobile engineers. The chrome-vanadium alloys are preferably made in the crucible or electric furnace, although the open-hearth process is also much used for the purpose. The open-hearth product, I believe, is somewhat uncertain, and while, for example, an open-hearth chrome-vanadium spring steel may be better than plain carbon-crucible spring, it is not to be compared with genuine crucible chrome-vanadium steel when properly melted. For excellent quality, this product constitutes the highest attainment of the steelmakers' art.

These alloys are in general made in a high carbon type, suitable for oil-hardened gears and springs, and in several low-carbon types, such as a case-hardening type for gears and a type suitable for oil quenching, followed by annealing for axles, shafts and steering knuckles. By judicious blending of chromium and vanadium and adjustment of the manganese and carbon one cannot only obtain all static properties that can be obtained from nickel, chrome nickel or silico-manganese alloys, but in addition obtain dynamic or anti-fatigue qualities far in excess of those displayed by any other alloys.

From a wide experience with all types of alloys, it is my opinion that where a better material than the best nickel steel is needed, and especially when dynamic excellence is sought, the appropriate types of vanadium-chrome steels may be unreservedly commended. They forge well and machine more readily than chrome-nickel steels of corresponding carbon percentages.

CHROME-NICKEL STEEL PROPERTIES

Chrome-nickel steels are usually made in a high and a low carbon type. The former is used for the oil-hardened gears and springs, and the latter for general structural purposes, such as axles, shafts, forged parts, and for case-hardened gears. The high-carbon type carries about 1-2 per cent of carbon, and the low-carbon alloy 1-4 per cent; the nickel as supplied by various makers varies from 2 to 3 1-2 per cent, while chromium from 1 to 1 1-2 per cent is usual. A nickel-chrome tungsten steel is sometimes used for springs. In general, nickel-chrome steels possess excellent static qualities, but the difficultics in heat treatment, forging and machining lead one to prefer the other type of alloys mentioned. Equally good physical characteristics can be obtained more cheaply in first cost and in shop costs from nickel or chrome-vanadium alloys. I shall speak later of the relative merits of these steels for oil-hardened gears and springs.

Silico manganese and silico chrome in medium carbons have had considerable popularity abroad for springs and gears. They also are made in low carbons. Their relatively low cost favors their use but their feeble resistance to shock and sensitiveness to heat treatment limit their use. When handled with great care they give good results in works well equipped for obtaining accurate results in their heat-treating operations.

Chrome steels in high carbons are much used for balls and ball races.

TUNGSTEN STEEL FOR MAGNETOS

Tungsten steel of special analysis is universally used for making magneto magnets. All statements and opinions to the contrary notwithstanding, the magnet steel now made in this country is rarely equaled in quality by foreign products. If foreign magnetos are superior to domestic ones it is because of their mechanical construction, and not because they possess, in general, better magnets.

The best alloys are none too good for automobile construction. When one has secured the best the market affords, the first step only has been taken to produce good parts. Next come the forging and machining and the heat treatment, for better or worse. It is money wasted to buy good alloys unless one is willing to study them sufficiently to know how to treat them and then to supply adequate facilities for so doing. It is not to be expected that small users will install complete testing laboratories, but a few pounds invested in having occasional tests made will be well spent. There are, however, many large concerns that could, and should, spend, say, $5,000, for which it is believed the whole, or a large part, of the following equipment could be obtained: An (ordinary) tensile machine, a microscope, electrical or gas furnaces capable of fine regulation, and a good pyrometer, preferably self-recording. The tensile machine can also be used for making Brinnell hardness tests, spring-deflection tests, etc.

In addition to these, some form of drop-testing machine, such as the Fremont, will be found valuable; a vibratory or repetitive impact test is nowadays considered a necessity; while cold-bending and torsion apparatus is useful. This equipment will be of small use unless a careful, conscientious man of sound judgment be put in charge.

The pyrometer is too often supposed to take care of itself. Too frequently it is never questioned, never calibrated. The best pyrometer of the thermo-couple type should be looked over at stated intervals, especially if in constant use. Protecting tubes should be frequently examined and renewed, and electrical contacts looked over, and occasionally the milli-voltmeter also should be tested. If one cannot afford a good pyrometer let him stick to the trained eye of a skilled man, but if he has a good pyrometer let him employ a skilled man. With it one can at least give orders in temperatures rather than in heat colors, and the laboratory and works can meet on an intelligent basis. Heat-treatment operations depend upon a solid scientific basis. By this I do not mean that steel essentially of inferior quality should be made to pass muster by heat treatment. On the other hand, however, it might be said that alloy steel in its so-called natural state, as it comes from the rolls, hammer or drop forge, is almost unfit for motor chassis construction.

DYNAMICAL EFFECT OF ALLOYS ON STEEL

Steel which depends upon alloys for a high elastic limit in its natural condition will have much less elongation than the same steel oil-tempered and annealed. For example, a chrome steel gave in its rolled condition 158,000 pounds elastic limit and 5 per cent elongation, with 9.4 per cent reduction of area.

The same steel oil-tempered and annealed gave 153,000 pounds elastic limit, 14 per cent. elongation and 52 per cent, reduction of area. In other words, the material was transformed from brittle to tough, from treacherous to safe, without materially affecting its elastic limit. A nickel steel similarly treated had its elastic limit raised 20 per cent., with the reduction of area improved and its elongation unchanged.

CASE-HARDENING VS. OIL-HARDENING

In the automobile trade there have existed two schools, so to speak, one believing in the case-hardened type of gear, and the other in the oil-hardened type. As previously mentioned, the chrome-vanadium, chrome-nickel and silico-manganese alloys are made in both high and low carbons. The former contain about 0.45 to 0.60 per cent carbon and enough other hardening elements, so that by merely quenching in oil from a bright red heat a surface hardening is produced sufficient for ordinary wearing purposes, while the hardness does not penetrate deeply into the gear, but leaves a core that is tough and strong.

The low-carbon alloys, with about 0.20 per cent carbon, require to be carbonized or case-hardened in order to produce sufficient surface hardening for wearing purposes after hardening. Several years of observation and contact with the motor trade lead me to prefer the case-hardened gear.

CONCLUSIONS FROM TESTS DATA

The result of direct tests upon thousands of gears of both types leads me to the following conclusions:

(1) The static strength of a case-hardened gear is equal to that of an oil-hardened gear, assuming in both cases that steel of the same class and appropriate analysis has been used, and that the respective heat treatments have been equally well and properly conducted.

(2) Direct experiments proved that the case-hardened gear resists shock better than the oil-hardened.

(3) As regards resistance to wear, the same type is incomparably better, although perhaps not as silent in action.

One of the leading makers of gears has proved this to his own satisfaction of late by an arrangement of shafts and gears whereby energy is transmitted through two case-hardened gears, in mesh with each other, to two oil-hardened gears. The gears are of the same size. The conditions of the test were severe. Five sets of the oil-hardened gears have already been worn out, while the original case-hardened gears are still in service, and show the tool marks.

Many people have a strong objection to case hardening. In most cases this is doubtless due to the fact that the operation of case hardening has not been reduced to a science. The depth of the "case" and the relation of same to the core; the time and temperature to produce certain results and the exact control of these conditions, together with an accurate knowledge of the material to be treated, are factors that enter into successful case-hardening practice. Points in favor of this method are easier machining of the blanks, and at least equal static and dynamic properties with less chance of injury in hardening.

BILLET-CUT GEARS VS. DROP-FORGED BLANKS

Parts like spur gears, bevel pinions and many shafts may either be drop-forged or cut from bars in automatic machines. Contrary to general opinion, many parts can be machined out of bars as cheaply as they can be from forgings. Moreover, I am firmly of the opinion that no steel is improved physically by drop forging, some steels, however, being less susceptible to injury than others.

In good steel-mill practice great attention is paid to proper finishing heats, and steel is brought gradually to size. In drop-forging work, in order to give sufficient plasticity to assume various forms in dies, it must be heated very hot. It is then frequently formed with the fewest possible blows. An investigation of drop-forged and bar-cut gears, the former being the product of one of the foremost drop-forging companies, showed, as the average of many tests, that under static test the bar-cut gears were fully 25 per cent. stronger, and their resistance to shock test was also much better. The difference cannot be exactly stated in percentage.

CASE HARDENING A SCIENCE

In reference to the proper procedure in case hardening, Dr. Guillet says:

As is well known, the operation of case-hardening consists of placing a steel in some medium capable of imparting carbon to it, at a suitable temperature. After a sufficient interval a steel is obtained the interior of which possesses the same percentage of carbon as before case-hardening, but the exterior of which is much higher (0.80 to 1 per cent.).

On quenching such a steel an extremely high degree of mineralogical hardness is obtained on the surface, while the center of the piece is non-brittle—that is, if the operation has been properly carried out. One generally uses steels containing 0.10 to 0.25 per cent. of carbon for case-hardening.

In order to avoid all brittleness in the interior and exterior of the piece, and at the same time to obtain a high degree of superficial hardness and a very regular degree of carburization (in carbon steels) it is necessary:

(1) To use a steel containing less than 0.12 per cent. of carbon, and with a low percentage of manganese (less than 0.30 per cent.); and

(2) To case-harden with a chemically definite material such as a mixture of 60 parts of charcoal and 40 parts of barium carbonate at a temperature between 1,550 deg. and 1,900 deg. F.—the higher the temperature the more rapid the case-hardening—and allow it, after the operation, to cool down just below the transformation point (about 1,100 deg. F.).

(3) To reheat the piece and quench it at 1,650 deg. F. (just above the transformation point of the center), this operation having the effect of rendering the center fibrous.

This operation has the effect of toughening the center, but the outside will be coarse-grained and brittle. The next operation, according to Guillet is:

(4) To quench for a second time at 1,475 deg. F. (above the transformation point of the exterior), to render the skin non-brittle.

In any case, the methods by which it is possible to obtain, with low-carbon steel, case-hardened pieces which shall not be brittle, are exceedingly delicate.

How different this is from the operation one too often sees, where the pieces are dumped directly from the case-hardening boxes into water!

HARDENING OF NICKEL STEEL

If one uses a good grade of nickel steel, low in carbon, the "case" hardens at appropriate temperatures. If one then takes the precaution to cool off in the boxes before heating for quenching, and then hardens at about 1,475 degrees Fahr., the results will be fully as good as, or better than, can be got by the most careful handling and double quenching of carbon steels. The saving in cost of the operation can be applied toward the greater cost of nickel as compared with case-hardening steel.

Better still, however, if nickel steel be used, is to give it a double quenching, too; then one obtains a really admirable product of extraordinary toughness and wearing qualities.

An ideal way of making nickel-steel gear consists in first annealing the blank, then rough machining, approximately, to size, and giving a light reannealing before taking the last finishing cut. Then pack in suitable mixture and carbonize to a depth of 1-64 to 1-32 inch, according to requirements, at a temperature of about 1,625 to 1,650 degrees Fahr. Cool in the pots, heat to about 1,500 degrees Fahr., and quench in hot brine or a calcium-chloride solution. This will put the core into excellent physical condition. Finally, reheat to 1,375 to 1,400 degrees Fahr., and quench in oil. The last operation will refine the grain of the case and harden it with best results.

It will be noticed that the temperatures for treating nickel steels are considerably lower than those advocated by Dr. Guillet for carbon steels. If methods like these be followed it is not likely that a very great difference would be noted between bar-cut gears and gears cut from drop-forged blanks.

In the case of medium carbon gears not to be case-hardened, but oil-hardened only, one would probably find a greater difference, and in this case we have no opportunity to restore the overheated forged blank by scientific heat treatment.

This, in addition to the greater chance of overheating and the greater difficulty of machining, also favors the use of case-hardened gears, assuming the case hardening is to be skilfully done.

MANGANESE SULPHIDE IN STEEL

To settle the question whether the dark gray substance, identified by Arnold and others in broken steel rails, is really manganese sulphide, as believed, Fay (according to *La Metallurgie*) prepared the sulphide by precipitation and incorporated it with iron in an electric furnace in such proportion that the mixture contained 0.08 per cent of sulphur. Under the microscope the metal exhibited the compound observed by Arnold. The greater part of the sulphur is retained by the manganese, the small remainder combining with the iron being disseminated through the mass of metal in the form of small grains which are uninjurious, so that a steel may contain up to 0.55 per cent of sulphur, and still be forgeable. On the other hand manganese sulphide is particularly harmful. the small particles elongating when the metal is rolled and forming starting points of subsequent fissures.

RECENT CLUB ACTIVITIES

A.C.A. GOVERNORS AND LAW COMMITTEE MEET

At a meeting of the governors and the law committee of the Automobile Club of America, held on the 11th inst., Congressman Olcott's bill, H. R. No. 1066, providing for federal regulation of automobiles engaged in interstate commerce or the postal service, was approved and its adoption by Congress urged.

With reference to proposed New York State legislation, the club has adopted resolutions favoring propositions as follows:

(1) An amendment of the existing law is preferable to the enactment of an entirely new automobile statute.

(2) A reasonable tax, based on horsepower, A. L. A. M. rules, is the fairest way of supplying revenue to the State.

(3) A reciprocity provision is desirable whereby cars owned and licensed in other States may be operated in this State under the home license, provided the home State allows cars owned and licensed in New York State to operate therein under the New York license.

(4) Professional chauffeurs should be required to take out a license. Owners should not be required to do so.

(5) The examination of owners of machines, or of chauffeurs with respect to their ability to run a car, is not practicable in such a way as to be productive of any useful results, but

(6) All licenses to whomsoever granted should be subject to suspension or revocation by some State authority either upon the recommendation of any Magistrate before whom the offender has been tried or upon its own volition whenever, after examination, any holder of a license is found to habitually operate in a way to endanger the life and safety of others.

(7) All license fees and fines and penalties collected for any violation of the law should be transmitted to the State Treasury within a reasonable time, and the proceeds of all license fees and penalties should be used by the State for the maintenance of its improved highways.

(8) The identification of cars should be made easier by enlargement of the number, from 3 to 5 inches in height, and by a requirement that at night the tail light should be so adjusted as to illuminate the number plate.

(9) Reasonable speed in lieu of arbitrary limits is still the desideratum.

(10) Any charge for registration designed for revenue should be collected on the ownership of the car, and be independent of the license fee required of drivers, which should be retained in a figure sufficient to pay the cost of issuing the same.

(11) Penalties should be measured to some extent by the violation, and in trivial cases should be supersedable in the Magistrate's discretion by an admonition.

(12) The function of bail is not punishment of an offender, but solely to insure his attendance in court when required; except in cases of accident, bail should not exceed $100 in amount and should be a matter which the Magistrate may dispense with, and, except in cases of accident, the Magistrates in the city, as well as in the country, should dispose of the case forthwith and summarily either by the imposition of a fine or by acquittal.

(13) Arrests in trivial cases should be superseded by a provision for service of summons or notice.

PHILADELPHIA LADIES' CLUB INSTALLS OFFICERS

PHILADELPHIA, Feb. 21—This "City of Automobile Clubs" has just witnessed the installation of the officers recently elected to guide the destinies of the Quaker City Ladies' Motor Club during next twelvemonth. They are: Mrs. Joseph J. Martin, Jr., president; Mrs. William Ingram and Mrs. Charles Snyder, vice-presidents; Mrs. H. B. Finck, secretary and treasurer, and the following board of directors: Mrs. Mary Martin; Mrs. Charles Murtha, Dr. Chatharine Sweeney, Mrs. David Ward, Mrs. O. W. Schaum, Mrs. M. L. Wallace, Mrs. Richard Filbert, Mrs. C. Kugler, Mrs. Stoerr and Mrs. Herbert Reading. The club's cozy quarters at the Hotel Majestic were tastefully decorated for the occasion.

CAMDEN, S. C., WANTS AN AUTOMOBILE CLUB

CAMDEN, S. C., Feb. 21—Dr. John W. Corbett and a number of other autoists at Camden, S. C., are making an effort to organize an automobile club. Camden and the country around has a goodly following of autoists, and that the venture will turn out to be a success is now assured. The question of association with the A. A. A. is also to be taken up, and it is the intention of the autoists around Camden to make a progressive campaign for good roads, equitable laws, and such other conditions as will add materially to the benefits which the automobile is bringing to the South.

LOUISVILLE CLUB WANTS MEMBERS BADLY

LOUISVILLE, KY., Feb. 19—Four hundred members by May 1 is the slogan of the Louisville Automobile Club. At present there are 343 members, and it is not expected that any great difficulty will be experienced in securing the additional members.

Officials of the Louisville Automobile Club returned from Chicago with the assurance that Louisville is to be included in the itinerary of the Glidden tour this year. The whole South is looking forward eagerly to this event, and it is expected that it will cause a great boom in automobiling in this district.

LAW AND THE AUTOMOBILE

COLUMBUS WANTS STATE LAWS BEFORE NATIONAL

Columbus, O., Feb. 14—At a special meeting of the Columbus Automobile Club a strong sentiment developed against the enactment of a federal registration law, such as is asked for by many members of the A. A. A. Discussion was produced showing that a federal registration act would benefit a comparatively small number of autoists, but that more benefit could be gained by working for uniformity in State automobile laws. To that end the request of the A. A. A. was laid on the table.

Secretary of State Carmi A. Thompson of Ohio has been invited to make an address at the convention of the National Automobile Owners' Association, to be held in Washington, D. C., February 15 to 17. At that time he will express the views of auto owners of the State on a federal registration act.

A large number of the members of the club are strongly opposed to having a race meet this year, as all meets in the past have proven failures financially. Some will make an effort to arrange a 24-hour race, however.

The show committee reported that 12,598 people were admitted to the automobile show and that the receipts from admissions and show space were $10,049.71. The expenses were $9,110.51, leaving a balance of $939.20. It was decided to hold another show next Winter. Plans were laid for an orphans' day, and a larger number of cars than ever before has been offered, so that the outlook is very favorable.

WAYNE COUNTY LEADS MICHIGAN IN STATE ROADS

LANSING, MICH., Feb. 21—A total of $381,455 has been expended by the State as rewards for the construction of county roads since the establishment of the State Highway Commission in 1905. The commission states that a total of 522 miles of State road have been built in the past four and a half years.

Since July 1, 1909, 160 miles have been built, making a total of nearly 400 in the entire past year. The majority of roads are constructed of macadam, the most expensive material, and the remainder are of stone and gravel. The fact that this is so is encouraging to the commission and proves that the counties are decidedly in favor of the best roads. Sixty counties are on the State reward list. The remaining counties have not yet applied for the privilege, but there are numerous applications on file for the building of new roads next Summer from these counties.

In the past fiscal year $116,604 has been paid by the department in State rewards. The average cost of building one mile of macadam road is $3,800; of gravel roads, $1,700. The State reward for one mile of macadam road is $1,000. For one mile of stone and gravel $750 is paid, for one mile of gravel road $500. and for one mile of clay gravel road $250. Those counties building the most roads under the State reward law are: Wayne, Port Huron Township, in St. Clair County, Saginaw, Bay, Grand Traverse, Manistee, Mason, Muskegon, Oceana, Kalamazoo, and all through the upper peninsula. In Kalamazoo preparations are being made to build 32 miles of State road in the coming Summer. In these counties the roads are almost without exceptions constructed of macadam.

WASHINGTON STATE PLANS A LONG TRUNK ROAD

SPOKANE, WASH., Feb. 11—Eleven hundred miles is the total length of the State trunk road planned for Washington by Governor Marion E. Hay, who was at Spokane conferring with officers of the Spokane County Good Roads Association, January 19 to 21. The road is designed to serve 75 per cent. of the population of the State, now estimated to be near the 1,250,000 mark, and will touch 11 cities, also taking in a large number of smaller towns between Spokane and Puget Sound.

The legislature appropriated $640,000 for state roads in 1909, but the money was spent in various places in the State, where sections of the proposed State road do not join. This year a tax of one mill has been levied, and it is estimated, and with the assessed value of the State at approximately $900,000,000, this will bring in $850,000 at least for use in improving roads. With this amount on hand some definite plant for a continuous State road can be made.

The largest appropriation ever made before by this State for roads was $225,000. Seventeen appropriations were made for improvement of State roads in 1909, but in no instance were these roads connected. It is believed a route should be selected for a State road that would best accommodate the largest percentage of residents and then every effort be used in a continuous betterment of that routed road.

The route, as now planned, will pass through or near Bellingham, Everett, Seattle, Tacoma, Centralia, Chehalis, Vancouver, Walla Walla, Spokane, Wenatchee, Ellensburg and again to Seattle. A road following this route would accommodate 75 per cent. of the people of the State.

The Northern Pacific railroad has promised to give six miles of an old roadbed in the southern part of Lewis county for a State road which will be a considerable help.

ROAD BUILDING NEWS

LEGAL OBSTACLES TO ROAD BUILDING REMOVED

INDIANAPOLIS, Feb. 21—The indications throughout Indiana now are that there will be a general resumption of township road building under the township gravel road law. The law has just been declared constitutional by the Supreme Court, in a reconsideration of the case appealed from Hamilton County. Many contracts throughout the State were in progress when the former decision was handed down and these were stopped. County treasurers refused to pay money as interest on bonds issued in the past, and Boards of County Commissioners refused to consider further issuance of bonds under new contracts. The decision of the court removes all question of the validity of the act, and has the effect of placing the stamp of supreme legal approval on all acts performed under the law. According to the act an entire township may be taxed for the building of a free gravel road on petition of a majority of the land owners affected by a stretch of highway to be constructed or improved when petition is made according to law.

THOUSANDS OF FARMERS FAVOR ROADS

Representative of the remarkable progress in the campaign for better highways, 1,000 farmers and automobilists of western Kentucky are preparing to visit Mayfield, a thriving town in southwestern Kentucky, on Thursday, February 24, and march to the court house, where the fiscal court will be in session that day. The purpose is to ask the court to take immediate action in the way of building gravel roads in that section. The farmers offer to pay half the expense in work and subscription.

SHOW BREVITIES

LOUISVILLE SHOW SPACE ALL TAKEN NOW

Practically all of the space has been taken for the third annual automobile show of the Louisville Automobile Dealers' Association, and it is expected that more space will be applied for than is possible to furnish. The exhibition will be held in the First Regiment Armory, March 17, 18 and 19. The committee in charge of arrangements have many details yet to work out, but it is announced that the display of motor vehicles will rival those of larger cities. The displays will be so arranged that those seeking information about cars they propose to buy or even concerning machines they own can be gained without the least amount of trouble or delay.

The building committee has hit upon an unique plan for arranging the floor space, and one which is declared satisfactory to all prospective exhibitors. The main aisle instead of running through the middle of the big building will take the form of a rectangle and enclose 12 large spaces. This central division will run from the main entrance, on the south, to within 15 feet of the balcony line, on the north. To the east and west of the broad aisle surrounding these central spaces will be located all other spaces for the display of automobiles. This arrangement gives every exhibit equal prominence. The north end of the armory will be reserved for the exhibits of accessories. It is expected that more than 100 cars representing practically every important type of car will be represented.

EQUITABLE CONSTRUCTION OF LAW OF REISSUE

JUST at this time, when the atmosphere is clouded by many issues, and the patent situation is uppermost in the minds of the men who have to do with the automobile and its ramifications, legal issues will be exploited in the press and many of the ideas which will be advanced will apparently be in conflict with each other. In the long run, the law of common sense, which is the under strata of common law, will have much to do with the settlements which will have to be made and subterfuge, while it is frequently embellished with gay plumage, rambles around sad at heart, realizing the while that the cold hard facts will serve as a stone wall and arrest further effort.

At this time it is believed that the question of reissue will be of the greatest value, and while it has divers angles, each one of which may have to be considered, for the present it will be enough to quote Renwick on patentable invention, page 151, paragraph 106:

"From the considerations previously set forth it would appear to be but just to the inventor and patentee that the construction of the law of reissue should be substantially as follows:

"1. That a patentee who holds a patent that is inoperative by reason of a specification defective or insufficient to protect the full real invention made by him previous to the date of filing his application for the original patent, or who holds a patent that is invalid by reason of his claiming as his own invention or discovery more than he had a right to claim as new, may legally apply for a reissue thereof with either an enlarged claim (in the former case), or with a reduced claim (in the latter case), and at any time within the term of the patent, provided the error has arisen by either inadvertence, accident, or mistake and without any fraudulent or deceptive intention; and provided further that the delay in making the application for the reissue is not unreasonable under the circumstances of the particular case.

"2. That the invention described and claimed in the reissue of the original patent is not to be restricted to merely the same invention which is claimed in the original patent, or even to identically the same intention which is set forth in the descriptive text of that patent, because either or both may be defective or insufficient; but is to be the same invention which the patentee invented or discovered as provided in section 4886 of the patent law as the condition precedent to obtaining the original patent.

"3. That if the thing correctly described and claimed in the reissue patent is found described in the descriptive text of the original patent, or is represented in the drawings thereof, or is embodied in the model or in the sample which the patentee filed in the Patent Office with his application for the original patent, either fact is conclusive evidence that the thing so claimed in the reissue is 'the same invention' specified in the statute for which the reissue may be legally granted; provided it was new as respects the state of the art, and was original with the patentee at the date of filing his application for the original patent.

"4. That the provision of the statute prohibiting the introduction of 'new matter' into the corrected specification of the reissue does not prohibit the introduction of matter which was omitted from the descriptive text, or from the claims of the original specifications, or from the drawings, by inadvertence, accident, or mistake, and without any fraudulent or deceptive intention, when such matter is found in either the model or sample, or in the drawings, or in the descriptive text of the original patent or of the application therefor on file in the Patent Office; but prohibits only the introduction of matter which is not found in substance in any one of these at the date of the original application, and which in such case is to be construed under the statute as not forming part of the original invention or discovery at that date.

"5. That, in accordance with the last clause of § 4910 of the Patent Law, matter new as compared with the specifications and claims of the original patent or amendatory thereto may be introduced into the corrected specification of the reissue of any other than a machine patent when there was neither model nor drawing filed in the Patent Office with the application for such other patent, 'upon proof satisfactory to the Commissioner that such new matter or amendment was part of the original invention, and was omitted from the specifications by inadvertence, accident, or mistake as aforesaid.'

"6. That the fact that an original patent is operative to the extent of what is described or claimed therein, is not satisfactory evidence that the patent is not inoperative by reason of a defective or insufficient specification to protect the full invention made by the patentee and which he intended to patent, and which he has a legal right to describe and claim in the corrected specification of the reissue, because it does not follow that when a patent is operative to protect a part of an invention it is not inoperative to protect the entire invention.

"7. That in accordance with the earlier decisions of the United States Supreme Court, the fact that a patentee has failed to claim in his original patent a material part of his real invention by reason of inadvertence, accident or mistake, and without any fraudulent or deceptive intention, is not a dedication of the unclaimed part to the public, which acts as an estoppel to the reclamation of such material part by a reissue.

"8. That the fact that some unlicensed party has engaged previous to the reissue of a patent in the manufacture of things embodying the part of an invention unclaimed in the original patent but subsequently claimed in the reissue of it, does not of itself render the reissue invalid, and is not conclusive evidence that there is an unreasonable delay in applying for the reissue.

"9. That if equity requires that a party who has engaged in nocently, before the application for a reissue, in the manufacture of things embodying only the part of the intention claimed in the reissue, should be permitted to continue the manufacture of the same articles subsequent to the reissue, then such party should be deemed to have acquired by reason of the delay of the patentee to reissue an equitable license to continue to make, use and vend to be used the same articles after the grant of the reissue. But the fact of such acquirement of an equitable license by such innocent party does not apply to nor inure to the benefit of any other party who engages in such manufacture subsequent to the date of application for the reissue and who infringes any one of its claims.

"10. That when claims and statements of invention are made in a reissue patent which are broader in scope than those made in the original patent, the fact that any claims, or any statements of invention, or both, of the original patent recite only a part of what is claimed in the reissue should not be construed into evidence that the patentee intended to patent no more than what is so claimed or set forth in the original, provided the inventor has sworn to the correctness of the reissue. On the contrary, the inventor's oath to the application for reissue should be considered as prima facie evidence of the correctness of the claims and statements of invention set forth therein. and the burden of proof to the contrary should lay upon the defendent in a suit.

"As to this last proposition it is a fact well known to all who act as solicitors of patents that an inventor always intends to claim in his original patent everything that is new in what he has done in view of the state of the art at the date of his invention. To presume that an inventor who has taken out a reissue with broader claims that existed in his original patent did not so intend at the time of his application for the latter and that he intended by his original patent to dedicate the unclaimed part of his real invention to the public, is to presume that every such inventor (using the classic language of the workshop) 'knew himself,' at the date of his original application, 'to be a born fool,' who voluntarily abandoned that which the law gave him the right to claim for himself; a presumption which is irreconcilable with the universal laws of human nature and with common sense.

FIRST SALT LAKE SHOW IS OPEN

Salt Lake City, Utah, Feb. 19—A new epoch in the local history of the automobile was inaugurated to-night by the opening of Salt Lake's first automobile show, in the Auditorium. There were none of the characteristics of an initial attempt visible, and, although but one day was allowed for the installation of the decorations, everything was complete. The decorations are mostly in light colors, the scheme being white and pale blue. Imitation marble pillars mark out the aisles, set amid masses of palms and flowers. Under a flood of electric light the effect is gay and summer-like.

The representation of different cars embraces the most varied types, the two extremes being the Brush runabout and the Chadwick "Great Six." The latter car is expected to enter in a number of competitions to be held during the summer. The Hupmobile had a good exhibit, and other comparative newcomers to the trade were the Everitt and the Warren-Detroit. The Botterill Automobile Company had a fine display of Pierce-Arrows, one of which was lent for the occasion by Mayor Bransford. On the same stand appeared the Pope-Hartford, interesting because of its victory at Portola. Chalmers-Detroit had a 30-horsepower touring car and a pony tonneau, and Hudson both the roadster and the new touring car. Moon was represented by the new 30-horsepower car.

The management is receiving much commendation for its quick work in preparing the show. The Auditorium was in use for other purposes up to midnight of the 18th. Five minutes later a force of 50 men was busy installing the decorations, which, of course, had been prepared outside.

BIG RALLY AT MILWAUKEE SHOW

Milwaukee, Feb. 21—The second annual automobile exposition of the Milwaukee Automobile Club, which opens in the new $500,000 Auditorium in Milwaukee, Wis., on the night of Washington's Birthday, will be the occasion for a big rally under the auspices of both the local club and the Wisconsin State Automobile Association, which are closely allied. President M. C. Moore, of the State body, will promote several extensive tours before the meetings of the various committees, while Secretary James T. Drought will lead a discussion of legislation, good roads, etc. Sessions will be held in the headquarters of the club, on the second floor of the Auditorium annex, which has been reserved for the use of members.

The dealers who will hold private shows are organized and their publicity of their shows and general work against the club show have created some feeling. Milwaukee business men have stepped in, fearing the split will be very hurtful.

MANY NEWCOMERS AT BALTIMORE

Baltimore, Feb. 21—There will be many cars new to Baltimoreans seen at the Baltimore show, which takes place at the Fifth Regiment Armory from the 22d to 26th, inclusive, of this month. These cars are the ones that have just established agencies here since the show of last March. Among those to be mentioned are: Washington, Apperson, Parry, Knox, Marion, I. H. C., National, Matheson, Stearns, Mercer, Alco, Velie and Dumont, Kline Kar and Manhattan truck, Rider-Lewis, Moline, Crawford, Chadwick, Rainier, E-M-F, Flanders, and Hudson.

MILESTONES FOR THE AUTOMOBILIST

Feb. 19-26........Minneapolis, Minn., Third Annual Automobile Show, Minneapolis Automobile Association. Walter R. Wilmot, Chairman, Hotel Nicollet.

Feb. 19-26........Newark, N. J., Essex Troop Armory, Automobile Show, New Jersey Exhibition Company.

Feb. 19-26........Los Angeles, Cal., Hamburger Building, First Annual Show, Licensed Dealers of Los Angeles.

Feb. 19-26........Salt Lake City Auditorium, Automobile Show, Utah Automobile Dealers' Association. W. D. Rishel, Manager, 1-5 East First South St.

Feb. 19-26........Cleveland, Central Armory, Annual Automobile Show under auspices of the Cleveland Automobile Show Company. H. M. Adams, Secretary.

Feb. 21-26........Cincinnati, Music Hall, Automobile Show, Automobile Club of Cincinnati. Jesse Lippencott, Chairman Exhibits Committee, Gibson House.

Feb. 22-26........Baltimore, Second Annual Automobile Show, Auto Club of Maryland, Fifth Regiment Armory.

Feb. 21-26........Portland, Me., Auditorium, Fifth Annual Automobile Show. F. M. Prescott, Manager.

Feb. 22-27........Milwaukee, Wis., Auditorium, Second Annual Automobile Show, Milwaukee Automobile Club.

Feb. 24-26........Binghamton, N. Y., State Armory, Automobile Show. R. W. Whipple, Secretary.

Feb. 24-Mar. 3...Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Mgr.

Feb. 28-Mar. 5...Omaha, Neb., Auditorium, Automobile Show, Omaha and Council Bluffs Automobile Dealers.

Feb. 28-Mar. 5...Kansas City, Convention Hall, Fourth Annual Automobile Show, Automobile Dealers' Ass'n.

Mar. 5-12.........Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park square.

Mar. 5-12.........Cleveland, Central Armory, Cleveland Automobile Club Eighth Annual Show.

Mar. 5-12.........Des Moines, Ia., Coliseum, First Annual Automobile Show, Des Moines Automobile Dealers' Ass'n.

Mar. 7-12.........Albany, N. Y., Armory, Automobile Show.

Mar. 15-19........Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

Mar. 17-19........Louisville, Ky., Armory, Louisville Automobile Dealers' Association Annual Automobile Show.

Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo, Launch Club. D. H. Lewis, Mgr., 760 Main St.

Mar. 21-28........Denver, Col., Convention Hall, Denver Motor Club's Annual Automobile Show.

Mar. 26-Apr. 2....Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

Mar. 26-Apr. 2....Montreal, Coliseum, Motor and Sportsmen's Show. E. M. Wilcox, Mgr.

Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

RACES, HILL CLIMBS, ETC.

Feb. 19-20........Los Angeles, Ascot Park Track, Track Races of Los Angeles Motor Racing Association.

Feb. 22...........Oakland, Cal., Hill Climb, Auto Trades Association of Oakland and Alameda County, Cal.

Mar. 5...........New York to Boston, Voting Trophy Contest, T. F. Moore, Manager, 91 West 103d St., New York City.

Mar. 19..........Altadena, Cal., Hill Climb, Licensed Motor Car Dealers' Association, Los Angeles, Cal.

FOREIGN SHOWS AND RACES

Feb. 18-26........Manchester, England, Automobile Show.

Feb. 20-23........Swedish Automobile Races and Trials.

Mar. 19-Apr. 3....Berlin Automobile Show.

Mar. 22...........Monte Carlo Elegance Competition.

Mar. 27-Apr. 4....Prague, Austria-Hungary, Automobile Show.

Mar. 28...........Brooklands, England, Easter Meeting.

Mar. 31-Apr. 8....French Spring Wheel Competition.

Apr. 2-24.........Turin, Italy, Automobile Show.

Apr. 27-28........Brooklands, England, Two-Day Meeting.

May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.

May 28-June 9...St. Petersburg, Russia, Automobile Exhibition.

June 2-8..........Prince Henry (German) Touring Competition.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

It may seem a little far fetched to blame the purchaser for the existence of things which fail to sustain the good reputation of the industry, taking it as a whole, but the fact remains that they would not be manufactured were there no prospects of sale. Reform, in so far as this condition is in demand, must come from the fountain head; the purse-string must be tightened until they discourage the undesirable effort.

When a banker wants a cashier, it is the latter who must sustain all his claims of competence; the banker takes his word for nothing; even the bond is scrutinized. The same cautious methods, if they are applied when an automobile is being selected, will lead to no more failures than banks have to put up with on account of dishonest or incompetent cashiers.

There is one characteristic which nests in the breast of every man; it is the very attribute which makes it possible to transfer the title of a valueless thing for money; when we want a thing we want it bad. Caution is the cure—let want wait until caution is satisfied. A man who has never owned an automobile can very well afford to let his funds earn four per cent for a little longer; long enough, in fine, to permit the maker of the automobile to prove his case.

A standard method of accomplishing a given task is good, because it induces a condition of stability, adds to speed of performance, and eliminates error. If a task is performed in some one way, it becomes a habit to continue the process, and habit, if it fastens its fangs upon a performer, no matter what the process may be, acquires a willing slave. There are habits which do no credit to anyone, but the habit of doing a thing in the right way is sure to be induced if the facilities afforded are right.

In an automobile as in everything else, the method of control, to induce habit, must be studied, and that it will be of the greatest advantage to make all control methods on a common basis, is true, for then habit would be acquired by drivers, and in an emergency, from force of habit, the right act would be performed, and safety would be more nearly assured.

That all automobiles relate to each other in some particular goes without saying, but differences, of which there are many, creep into the respective designs so freely that it becomes extremely difficult to realize by what method averages of all can be made to serve a good purpose. In a cylinder, if the mean effective pressure is determined, it gives a means by which the power of the motor may be resolved, and when the value of an alternating current of electricity is being investigated it is necessary to take the square root of mean square of the instantaneous values to evolve the results desired.

When all the motors of the year are taken and averages are struck, the result is something new; it is not representative of a single motor of the whole number taken, and, after more than a little deliberation, the inclination is to enquire what does this average represent?

In taking all the designs into account during the process of averaging, it is necessary to include the designs which are below standard, and to whatever extent they are inferior they drag the average down; is it proper to do so? One way of viewing it leads to the answer yes; every art has its good and its bad; the art is influenced by both; unless the bad can be eliminated it must be included; an average of the good and the bad will be superior to the one and inferior to the other; it is as a gain, on the whole, to advance the bad to the average, at the cost of the good.

The owner of an automobile, if he takes advantage of wisdom, must regard personal safety ahead of many other considerations. If he has an exaggerated ego to the high disregard of personal safety, then, the safety of others, if it is taken into account, will show, at least, that he is endowed with a spirit of consideration for his neighbors. When an automobile is new, if it is reasonably well made, it may be speeded to the maximum of its ability, but as age overtakes it, unless the power plant deteriorates in about the same ratio as the car as a whole, the time may arrive when the effect of speed upon the strain members will make its mark. The greatest chance for trouble of the character which may end in the loss of life will follow when a touring car is used for two or three years and then put through a process of repair with the object of turning it into a racing automobile, which process is ended by the simple expedient of overhauling the motor, removing the heavy touring body, and substituting a light one. True, the speed of the car will be increased, but the strains induced in the parts will increase as square of the speed.

STATEMENT FROM A. L. A. M. ON PATENT SITUATION

BEFORE GOING ABROAD, COLONEL CLIFTON MAKES A DECISIVE AND AUTHORITATIVE STATEMENT OF THE PRESENT AND PROSPECTIVE PATENT SITUATION

WITH a campaign of education that is expected to be of far-reaching effect, those interested in the Selden Patent are endeavoring to show car buyers the many advantages of buying cars licensed under that patent which Judge Hough in the United States Circuit Court of New York held recently to be valid and to cover the modern gasoline automobile.

For the first time since the decision, Charles Clifton, the president of the Association of Licensed Automobile Manufacturers, has consented to talk on the subject. Among other things in the interview given out yesterday he says:

"Many promoters, pointing to the profits made by a few of the old-time manufacturers, encourage the formation of companies and try to induce innocent people to place their money in the enterprises, holding before them the alluring idea of getting rich over night. Such affairs it seems to me, are doomed to failure and the stockholders are almost certain to lose every dollar they supply.

"The success of a few old companies, headed by excellent business men, has induced others to start manufacturing, ever since Judge Hough's decision. Some of them may propose to put out good cars and others to put out inferior cars. Scores of such companies may not get beyond the experimental stage and many who do get out a few cars may depart from this business life, leaving behind them products for which no parts can be obtained. Those who would start companies at this time forget that the makers now getting profits from the business are old-timers, who after years of work, have built up a line of tried products and an organization for handling them, which cannot be duplicated without a great amount of work at this keen competitive period of the industry.

"Some patent attorneys, not appreciating the importance of the decision, or for other reasons," continued Mr. Clifton, "have evidently encouraged people to manufacture cars in the face of this decision; a procedure which may result in a heavy loss for those endeavoring to enter the field at this late date.

"The trade is well informed on the patent question, and since the decision, more than forty concerns have applied for and have been granted licenses. The Association of Licensed Automobile Manufacturers has the right through its Executive Committee, to say who shall and who shall not be granted the protection of the patent, although the licenses are granted by the patent owner, the Columbia Motor Car Company.

"On the other hand some innocent buyers of motor cars have failed to appreciate the importance of Judge Hough's decision and have bought cars that infringe the patent. How unnecessary it was for them to purchase such cars is evidenced by the fact that 76 standard American cars and two imported cars are now licensed. These factories are producing cars of all classes and for all prices, from $485, the lowest-priced car in America, to the most luxurious machine of the automobile and coach-builders' art, with the makers in strict competition with each other, a fact well known by the trade and buying public.

"In the buying of cars it can be readily seen that there is no occasion, with almost every important maker having a license, for any person to take chances of litigation by the purchase of an unlicensed car, to say nothing of the difficulty of trading that car in exchange for a licensed car when a new purchase is contemplated," added Mr. Clifton. "Last year the licensed manufacturers made almost 95,000 cars, or about 85 per cent. of the estimated production and this year are expected to market not less than 160,000 machines.

"With a view of protecting the public and thereby increasing the popularity of the automobile, it has not been the policy of those who controlled the patent, to extend its protection to new and untried, or doubtful products.

"One shouldn't be pessimistic on the future of the automobile, but it doesn't take much of a prophet to figure that the going concerns in the business to-day, almost all of which are licensed under the Seldent patent, should be fully able to care for the demand for motor cars.

"To prevent the unthinking from investing in new automobile companies or buying unlicensed automobiles," concluded Mr. Clifton, "it is deemed proper to issue this statement so that everyone may be advised as to the facts and past history of the litigation which resulted in Judge Hough's decision of last September, wherein he upholds the validity of the patent, declaring it to cover the modern gasoline automobile. Suits may be brought under this patent for infringement by manufacturers, by dealers, or by users of pleasure or commercial gasoline automobiles, and it is the intention of the owners of this patent to protect the exclusive rights secured by it to those who have become licensees by commencing suits against infringers of it."

INDEPENDENTS EXPECTED TO TAKE APPROPRIATE ACTION

NOW that the A. L. A. M. is indicating by its public announcements the action which is expected of it in view of the decision of Judge Hough of the United States Circuit Court of New York, and considering the fact that the Licensed Association represents only 76 of the total number of automobile makers in this country, it is scarcely news to announce that the independents are quietly looking out for themselves, and while they all evince willingness to join the A. L. A. M. under favorable terms, they are hustling while they wait.

To what extent the new independent organization has assumed definite form it is extremely difficult to indicate, because of the reluctance on the part of the possible members to disclose any of the doings, to some extent, in view of the effect such action might have on the A. L. A. M. when considering membership application, and again in view of the considerable number of unprotected automobile makers who have failed to do anything.

It may be a surprising statement to make, but there are automobile makers in this country who are not at all familiar with the patent situation, and, in some cases, they do not seem to know that there has been a long-drawn-out contest in the courts, and that a decision has been rendered. The organizers of the new independent association point out that headway is slow, and that there is much danger in courting publicity at this time, and they are reluctant to disclose their plans, which, however, according to indications, are well advanced.

In a very few cases, when the newly organized companies discovered that to go into the automobile business these days is to court an action at law, they quietly withdrew from the field, but the many companies with plants on their hands, and product in a half completed state will scarcely be able to back out.

Henry Ford, in commenting on A. L. A. M. attitude, stated to the representative of THE AUTOMOBILE that he will have something to say, which will be the result of sufficient deliberation to make it sound attractive.

DOUBLE SHOWS TO BE HELD NEXT WINTER

MADISON SQUARE GARDEN TO BE REARRANGED SO AS TO GIVE MORE SPACE--COMMERCIAL AUTOMOBILES WILL MAKE UP SECOND HALF OF THE DUAL EXHIBITION

OWING to the many additions to the ranks of the Selden patent licensees, the Association of Licensed Automobile Manufacturers has planned a double show for Madison Square Garden, New York, in 1911. The dates selected are January 7 to 14 for pleasure vehicles, reopening on Tuesday, January 17 and closing on the 24th, for commercial vehicles.

Properly to care for the exhibitors, arrangements have been made by the show committee of the A. L. A. M. to rebuild the interior of the Garden, thereby securing 20,000 square feet more floor space than has been available at previous shows. This will be accomplished by extending the elevated platform so that it will be 50 feet wide, with another platform overhead, extending from the level of the balcony. When this is accomplished and the commercial vehicles are cared for at the second week, the show committee can accommodate 80 exhibitors of vehicles in spaces of the same size as those used at the last show. In other words, the new construction will give sufficient room to care for all the present Selden patent licensees. There will also be accommodations for 27 exhibitors of motorcycles and about 300 motor and accessory manufacturers.

The plan of a double show that will give proper space to the pleasure vehicle makers and care for the fast increasing number of commercial car manufacturers has been the subject of long discussion among those interested, and while the expense and work involved will exceed that of any previous exhibition, the affair is certain to be representative of the industry.

Work will begin early in July on the preparation of the interior construction, which will be made in sections to permit rapid installation. When the pleasure vehicle show closes on Saturday night the pleasure vehicles will be removed and their places taken by commercial cars. The signs and carpets will also be changed, but the main decorations will be carried in both.

Many of the members of the Licensed Association are now turning their attention toward commercial vehicles and will have their products ready for the fall trade and for exhibition at the January show. It is believed that the double show of 1911 will exceed in all respects any previous exhibition of motor-driven vehicles. The contract with the Madison Square Garden Company was signed by President Clifton of the A. L. A. M. before leaving on his southern trip.

FIRST NEWS OF BOSTON'S BIG AUTO SHOW

BOSTON, Feb. 19—When the automobile show followers come to Boston for the last of the "big" motor vehicle displays of the season, that of the Boston Automobile Dealers' Association, which opens in Mechanics Building the evening of March 5, they will be impressed with the fact that the show season has nearly run its course and that the riding season is at hand. Boston's show is the Spring show, the final great assembling of the examples of the year's product, before they go into the hands of the consumers, and the manufacturers turn their attention to the designing of models for the succeeding season. Thus it is appropriate that in the setting of the Boston show the idea of springtime should be emphasized. This is the keynote of the decorative scheme which Manager Chester I. Campbell has prepared. The show will depict a typical New England countryside, garden, orchard and fields, in the Spring of the year.

To carry out this idea to the most realistic point growing plants and flowers are to be used to a degree never before attempted in an automobile show. For months one of the largest conservatories in the vicinity of Boston has had under glass hundreds of shrubs and plants which have been brought along so that they will be in bud and full bloom during show week in Mechanics Building. Apple orchards have been despoiled to furnish the material for the orchard that will be a feature of one department, and many an old fence has been torn down to supply materials for the show. Great paintings, depicting New England rural scenery, have been made, and immense quantities of material are awaiting the day when the building will be given over to the decorators.

Grand hall will be the garden, and exhibition hall, adjoining, the orchard. In grand hall the main divisions between spaces will be of neatly trimmed lilacs in bud and bloom, while spirea covered with dainty white blossoms will make up the side divisions. At the bases of these shrubs will blossom thousands of vari-colored tulips, giving a lively touch of color to the whole. All around the side walls will be panelled paintings depicting rural landscape, while on the stage will be a painting 100 feet long and 25 feet high, forming the background. These paintings are intended to give an appearance of spaciousness to the hall. The floor coverings will be of a mahogany-colored material and numerous gray-green rugs will be scattered about. The signs on wrought-iron standards with white lettering will be in keeping with the decorative scheme as a whole.

The first balcony will have a colonnade with vine-draped rafters extending to the base of the second balcony. Vines in profusion also will be used over the balcony front. The bandstand will be on an elevated platform over the second balcony, leaving the main floor free from this obstruction.

In exhibition hall each of the one hundred or more posts will be covered with bark slabs to give them the appearance of tree trunks. At the tops apple tree branches will spread out, and they will be gay with artificial foliage and apple blossoms. Old-fashioned rail fences will serve as division lines between exhibition spaces, and there will be a painted landscape all around the back wall of this hall. The flooring will be similar to that in grand hall, and the signs will be in keeping with the orchard atmosphere. Illumination will be by electric lamps, which will be used in such profusion that no part of the great hall will be dark day or night.

In the basement there will be a typical New England brick inn to house the restaurant, and the decorations for the overflow pleasure car display and for the commercial vehicle department will be of special design, each post being covered with tapestry finished material and carrying arches that are to be studded with electric lamps. The basement floor coverings will be of the same material as that in the departments on the main floor. For the motor cycle and accessories divisions on the balcony level a decorative scheme in harmony with that below though not as elaborate will be employed.

Those who have seen the drawings and materials for the Boston show decorations are enthusiastic over them and predict that the Boston show of 1910 will be the most successful in the long line of attractive exhibitions that have been held in Mechanics Building. Every inch of space has been sold, and there seems a probability that some of those who were unable to secure space will unite in an independent show nearby.

SOUTHERN CALIFORNIA SHOW SUCCESSFUL

Los Angeles, Cal., Feb. 18—The southern California show opened a few days ago in the Grand avenue rink and every indication points to its being one of the most successful exhibitions ever held on the Pacific coast, more than 5,000 people attending the opening. The show colors are green and white and the building is lighted by means of 5,000 incandescents which show to advantage the many beauties of the cars on view. Small cars are in the majority, although the higher-priced models also are in evidence, while the Californians show they are up-to-date by displaying bodies of the gunboat or torpedo type. Walter Hempel, manager of the show, is given credit for producing a most satisfactory affair and as a curtain-raiser yesterday afternoon he had a parade through the city streets of 300 cars, in which the feature was the struggle for the prize offered for the concern having the greatest number of cars in line. This prize was captured by the Standard Motor Car Co., which had fifty Ford cars in the procession, the natty machines coming from San Bernardino, Glendora, Riverside and Redlands. Of the cars on exhibition all of them are well known in the East with the exception of the Tourist, which is a California product and which is shown by the California Automobile Co., which has on view eleven Tourist models as well as showing the Firstone-Columbus torpedo. The Standard Motor Car Co. has the Ford and Velie, the W. J. Burt Motor Car Co. has the Auburn, the Vail Motor Car Co., Pennsylvania; Bosbyshell-Carpenter Motor Car Co., Dorris; W. A. Evans, Waverly electric; Williams Auto Co., Petrel; Burkhard-Crippen Motor Car Co., Lexington; A. N. Jung, Sterling; National Auto Co., National; Hawley-King Co., Grabowsky truck; Lane Steam Car Co., Lane steamer; Newell-Mathews Co., Whiting and Westcott; Tri-State Auto Co., Hupmobile; W. K. Cowan, Rambler; Durocar Mfg. Co., Duro; Pioneer Commercial Auto Co., Reliance; Brush Automobile Co., Brush; Import Motor Car Co., Halladay; American Auto Co., Rider-Lewis; Fred A. Cornell Auto Co., Fal-car; Pico Carriage and Automobile Co., Paterson; Stanley Steamer Co., Stanley steamer; M. S. Bulkley Motor Car Co., Autocar; Mountain Brothers, Royal and Midway. In addition there are displays made of the Fiat, Great Western, Empire and Rauch & Lang electric.

CLOSING NOTES OF HARTFORD SHOW

The best show ever, is the report of the Hartford Automobile Dealers' Association at the conclusion of the one week's exhibition at Foot Guard armory. The show opened Monday of this week and closed this evening and practically all of the exhibitors of cars express themselves as well satisfied with the results attained. Certainly there is much interest in cars in this city as was proven conclusively by the heavy attendance throughout the week. More people visited the show this year than last season and there seemed to be more genuine interest by people who came to see the cars and not merely to look at them as something attractive. Naturally the lower-priced cars were centers of interest. The Maxwell, Flanders, E. M. F., Reo, Ford and Empire; 20 of the lower-priced cars were highly regarded. The Hupmobile surprised many an owner of a larger car when it came down to a real demonstration. The Velie and the Everitt "30," both of which are new to this section of the State, were well thought of. Practically every dealer in the show reports sales and enough demonstrations have been booked to keep them busy for some time to come. At the Park Casino the Jackson was very popular and many cars were signed up by the State agents. This car was in both shows; so was the Winton. The Belmont, another new Connecticut product which hails from New Haven, was a feature of the Casino show. Here, as at the Foot Guard armory, good business is reported. The Packard Motor Car Company of New York has several natty models on exhibition in the salesrooms on Allyn street.

DATE OF CONNECTICUT RUN NOT SETTLED

Hartford, Conn., Feb. 19—The final dates of the forthcoming All-Connecticut Endurance Run which is to be held under the auspices of the Automobile Club of Hartford have not been decided upon. May 1 is the date named by the American Automobile Association, but this date is too early for the Automobile Club of Hartford, and while no definite promise has as yet been received by the contest committee it is the general opinion that the dates desired by the club, that is, May 19, 20 and 21, will be conceded by the national body. The route as now laid out, which covers three days' travel, touches the border of New York State within a half mile, to within three miles of the Massachusetts border and within four of the Rhode Island border and in some places the route lies along Long Island Sound. While the run is confined to the State of Connecticut it affords about as hard a test as could be devised, as the hilliest parts of the State will be traversed on each of the three days of the run. The referee of the event will be Lewis A. Speare, president of the A. A. A., and S. L. Butler, chairman of the contest board of the A. A. A., will be assistant referee. The judges will be A. G. Batchelder, chairman of the executive committee of the A. A. A., and Alfred Reeves, general manager of the A. L. A. M.

BUDLONG DECLINES HEAD OF N. Y. DEALERS

Now that the licensed dealers in New York are in organized relation, all that remains is to complete the details of the plan, and find some one of the members who will be willing to accept the presidency and take the brunt of the fight. That there will be a certain amount of disagreeableness is to be understood, since otherwise there would be no occasion for segregating out the licensed dealers and lining them up. M. J. Budlong, who is the president of the Packard Automobile Company of New York, and who participated in the preliminaries of this new organization, did not indicate, until he was offered the presidency, that he would not be in a position to accept same. As a result, taking the last report, the committee is trying to find someone who will.

It is possible that General John T. Cutting may be induced to accept the office. It is also thought that R. D. Garden may be persuaded to assume the difficult task. At all events, it is thought that the presidency will be taken care of at a meeting which is scheduled to take place at an early date.

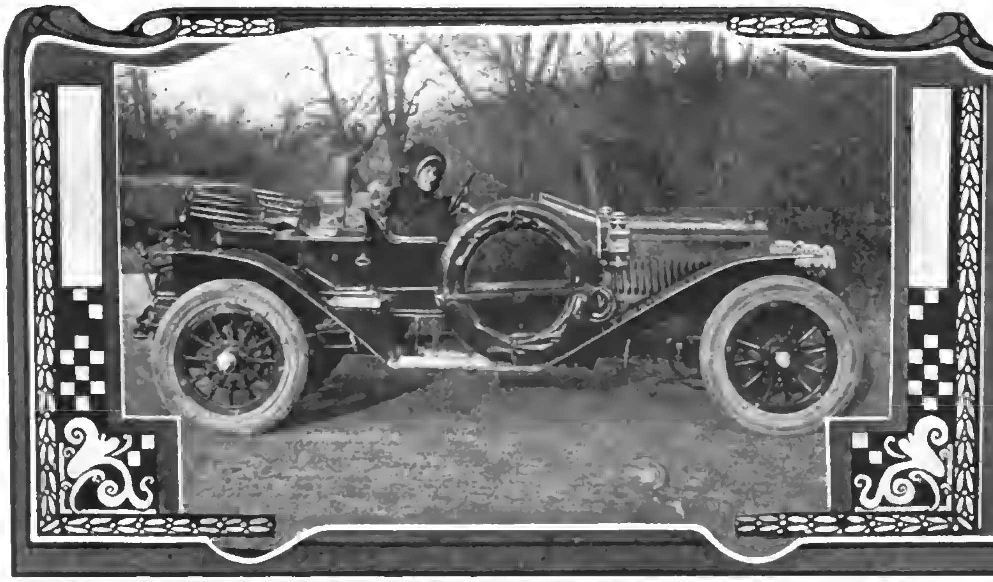
The directors of the Licensed Automobile Dealers' Association are: Carl H. Page, Chalmers; George W. Bennett, White; General John T. Cutting, Olds; Harry Fosdick, Lancia; C. P. Skinner, Mitchell; R. D. Garden, Pierce; M. J. Budlong, Packard; Sidney B. Bowman, Marmon; James Joyce, Alco, and John F. Plummer, Locomobile.

CHANGES FOLLOWING U. S. MOTOR DEAL

Hartford, Conn., Feb. 19—Fred A. Law, superintendent of the Columbia Motor Car Company, severed his connection with that concern this noon and leaves for the West, where his friends say he is to become affiliated with the General Motors Company. Before his departure from the plant, Mr. Law was called into the general offices and presented with a set of solid silver table ware. The presentation speech was made by Henry A. Castle of the sales department, and Mr. Law expressed his appreciation in a few well-chosen words.

COLONEL CLIFTON TO CARIBBEAN SEA

Charles Clifton, president of the Association of Licensed Automobile Manufacturers, and treasurer and general manager of the Pierce-Arrow Motor Car Company, leaves to-day with Mrs. Clifton for a month's cruise on the steamship Moltke to the West Indies and the Spanish Main. Since the decision in the Selden Patent case, Col. Clifton has devoted a great deal of time to Association matters. He expects to secure a well-earned rest on his trip to the Caribbean Sea.



GARAGES

The Briarcliff type of body, originated by the Lozier Motor Company, and shown above on a Lozier car, is very popular among those who desire a rakish and speedy-looking design

Martin Kelley and his son, George Kelley, have secured an interest in the Winnipeg Garage Company, Ltd., of Winnipeg, Canada. They have purchased all interest held by R. M. McLeod and C. McLaughlin. Mr. McLaughlin will remain as manager of the company for the present. This garage handles the Cadillac and Franklin, as well as the Columbus and Babcock electrics.

Green Bay, Wis., will have a new garage, Frank R. Buchholz having awarded contracts for the construction of a fireproof brick structure for D. G. Meyer, a well-known agent now located at South Washington and Doty Streets, Green Bay. The building will cost $10,000. It will be steam heated and have all modern conveniences. It is to be ready June 1.

H. E. Coffin, vice-president of the Hudson Motor Car Company, and president of the Society of Automobile Engineers

The Cream City Brewing Company, Thirteenth and Vliet Streets, Milwaukee, Wis., is building a large private garage for its delivery trucks. The company is using motor trucks almost exclusively. The building will be 100 by 160 feet in dimensions, of reinforced concrete construction, with complete equipment and repair shops.

James Beaver and Philip Fleming, of Lincoln, Ill., have closed a contract with Frank Klatt for the erection of a concrete or brick garage with concrete floor, 60 by 70 feet, on Broadway, which it is hoped will be ready for occupancy by April 1. They will handle the Hudson, Haynes and Chalmers cars.

The Auto Shop Company, Cleveland, agents for the Thomas car, will move to a large garage building being erected for them on Euclid avenue. After locating in new quarters three other cars will be added to the line.

The Gordon Motor Company, Inc., Richmond, Va., has, on account of increasing business, purchased a large lot on which it will erect a modern garage and salesroom at an estimated cost of $50,000.

The Prothers-McGinnis Auto Company, of Baraboo, Wis., has arranged for the erection of a large building during the coming Spring, which will contain its garage as well as a large equipped machine shop.

The Ames Auto Garage Company, of Orrville, Ohio, has been purchased by the Champion Thresher Company. The garage will be enlarged, and R. C. Taylor has been appointed general manager.

B. H. Smith, of Caro, Mich., is about to erect a one-story building to be used as a garage and repair shop, in which will be handled supplies, sundries and automobile accessories.

In Cleveland, Ohio, Harry S. Moore, agent for the Stoddard-Dayton, will open a garage and salesroom on Euclid avenue, continuing his place of business on Crawford road.

Peter Esswein, of Columbus, O., has taken out a permit for the erection of a brick garage building on Wall street between Rich and Walnut streets.

The Foss-Hughes Motor Car Company, of Philadelphia, agent for the Pierce-Arrow, is opening a new garage on North Broad street.

The Thomas Automobile Company, of Pittsburg, will build a new garage at once at 5509 Baum street, East End.

AGENCIES

Fig. 1—Kenny Motor Car Company, Brooklyn, showing a night scene and decorated electric lighting. This is Brooklyn headquarters for Rambler automobiles

The new Wisconsin branch of the Buick Motor Company will soon have permanent quarters in Milwaukee. Contracts are about to be awarded for the construction of a four-story fireproof garage and salesroom building on Wisconsin Street, near the Government building and postoffice. The plans have been prepared by James Peden, supervising architect for the General Motors Company, and Brust & Philipp, architects, Milwaukee, have been selected to superintend the work. It is planned to have the building ready for occupancy on May 1. The offices of the branch, in charge of George P. Hewitt, Wisconsin manager, are now located at 505 Matthews Building, and the temporary garage on Thirteenth street. In addition to the Buick the branch distributes the Welch. The permanent garage is at the end of Wisconsin Street, the main artery of Milwaukee.

The Ideal Auto Car Company has been organized by Ole G. Kinney, of Colfax, Wis., and headquarters have been established in Eau Claire, Wis., for the distribution of the Ford and Brush in northeastern Wisconsin. The temporary location is in the Bonnell Carriage Company's works, and in the spring a large garage will be erected on South Barstow street, Eau Claire.

Rainier motor cars will be represented in Maryland by G. H. Ghaab, 116 W. Mount Royal avenue, Baltimore, Md. R. M. Robinson, Albany, has closed the agency for the Rainier in that city and district. Mr. Robinson also represents the Reo and has taken on the Rainier to supply the demand for a high-class car in central New York.

The Beaver Valley Motor Company, of Rochester, Pa., has been organized, with Stanley Q. Brown, of Rochester, as manager. It will have headquarters in the Traction Building, recently vacated by the Auto Sales Company. Mr. Brown has secured the agency for the Reo and Oldsmobile cars.

The E. W. Clark Auto Company, of Fond du Lac, Wis., agent for the Jackson, has now taken on the Fuller. President E. W. Clark states that the year's allotment consists of 58 carloads, 60 cars having been already received. The company also handles the Buick in the Fond du Lac district.

The Sterling car, manufactured in Elkhart, Ind., will be represented in Cleveland by the Sterling Motor Sales Company, a new company, with a capital stock of $30,000, of which J. C. Koepke is manager.

The F. M. Hacker Auto Sales Company has opened a salesroom at 18 Spruce street, Lewiston, Me., and will handle the Mitchell and Reo in Androscoggin and Sagadahoc Counties.

Thomas Salverson, of Waupaca, Wis., has been appointed a district agent for the Mitchell, of Racine, Wis.

The Tri-State Garage Company has started business in Uniontown, Pa., at 74-76 East Fayette street, with Jno. C. Shaw as manager. The company will handle the White and Ford cars.

The Cole "30," according to arrangements just closed, will be handled in Chicago by the Standard Automobile Company. F. C. Bailey is the manager of the local concern.

Oliver B. Brown, formerly of Brookhaven, Miss., has opened a salesroom at 605 Baronne street, New Orleans. He has the local agency for the Stevens-Duryea.

Fig. 2—M. J. Budlong, general manager of the Packard Motor Car Company of New York. Formerly general manager A. L. A. M.

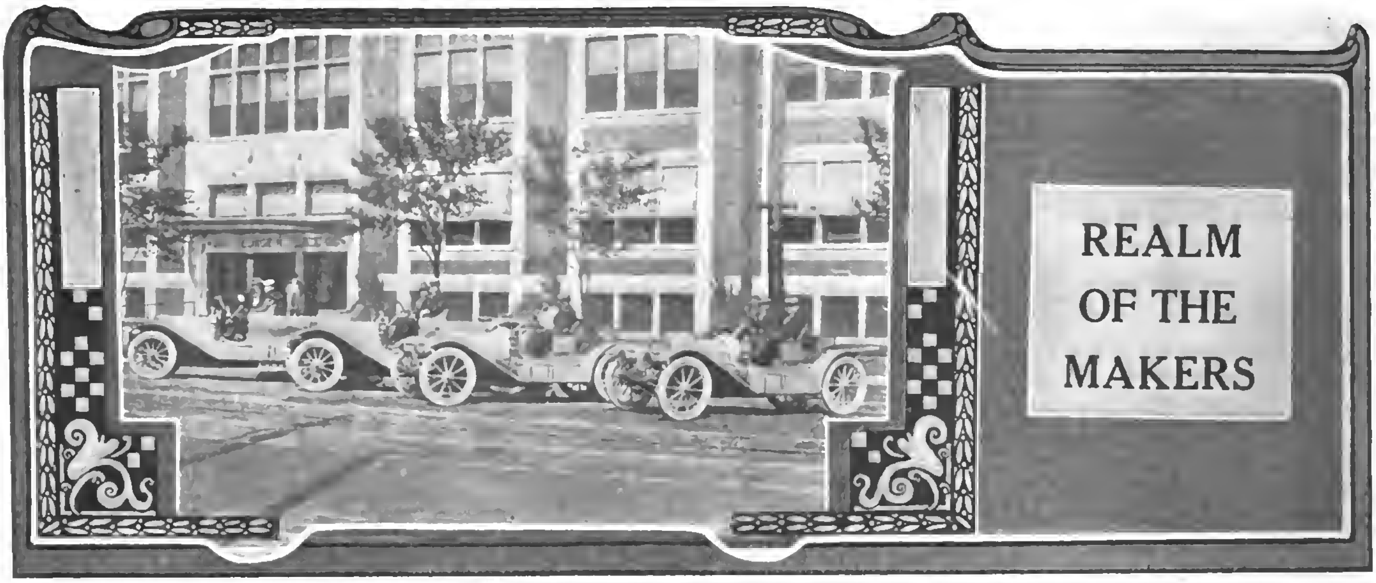


Fig. 1—A view of the Administration Building of the George M. Pierce Company, on Elmwood avenue, Buffalo, with a string of Pierce-Arrow automobiles in the foreground

The affairs of the Petrel Motor Car Company, 480 Virginia street, Milwaukee, Wis., were placed in the hands of a receiver on February 11 on petition of creditors. Referee Nye appointed the Milwaukee Trust Company receiver, under bonds of $1,000. The proceedings were begun by the Hess-Bright Manufacturing Company, Philadelphia, which has a claim of $220; the Herman Andrae Electrical Company, Milwaukee, with a claim of $239.62, and the Julius Andrae & Sons' Company, Milwaukee, $316.38. The involuntary bankruptcy petition cites that the company's estate is worth $30,000. The Petrel Motor Car Company was organized a year and a half ago, and established a factory in Kenosha, Wis. Later, through proper inducements, Milwaukee became the home of the company. The product is a popular-priced car, using the Waite friction transmission exclusively. It is believed that the company will be able to extricate itself from this legal difficulty in due time.

The Cartercar Company at the Detroit Automobile Show received an order from the Kellogg Toasted Corn Flakes Company, of Battle Creek, for twenty-four Cartercars, model "H," touring type. Instead of being equipped with the regular body these will be fitted with a specially constructed body built in the exact shape and proportions of the package of the goods manufactured by the purchaser. It is said that about $30,000 is involved in the deal.

The Columbus Buggy Company, of Columbus, O., announces that it will manufacture during 1910 100 electric and 1,500 gasoline cars. In addition to the models that have been placed on the market, the company has completed two new models, to be known as 74A and 1010. The model 74A is a gasoline runabout, with a torpedo body, built on entirely new lines. The style 1010 is a two-passenger electric, modeled after a runabout.

The Reliance Truck and Garage Company, incorporated several months ago, has announced the organization as follows: Theodore Leonard, president; Andrew Timberman, vice-president; George C. Bohn, secretary, and Frank Tray, treasurer. The company will open a garage and sales agency for the Reliance trucks.

Reports from Lima, Ohio, state that the Gramm-Logan Motor Car Company, of Bowling Green, Ohio, will invest half a million dollars in a plant in that city with a capacity of 1,500 cars annually. The plant at Bowling Green will not be abandoned, but will be devoted to the building of taxicabs.

The first shipment of Mitchells to the Orient was made last week, when a carload of 1910 models left Racine, Wis., for Seattle, Wash., where they will be loaded on the Puget Sound's Japan mail steamers and unloaded en route at Manila, P. I.

The manufacturers of the Babcock Electric Carriage claim a car which has made record time on the level and on hills, also that it has made more miles on one charge under the same conditions than has any other electric vehicle. This concern presents eight models.

It is stated that the Hudson Motor Company will build a $400,000 plant in Fairview, Mich. A site of 106 acres has been bought, and it is believed that the railroad will build a freight and passenger station in the vicinity.

The first shipment of E-M-F cars has already been disposed of.

Fig. 2—S. D. Waldon, general manager of the Packard Motor Car Company of Detroit

NEWS IN GENERAL

Fig. 1—Special design of hospital ambulance made by the Knox Automobile Company and used to very great advantage at the Springfield Hospital

It is authoritatively announced that the Eagle Manufacturing Company, of Appleton, Wis., has decided to reorganize at once, increase its capital stock, and engage in the manufacture of motor cars. The largest interest in the company is owned by the Saiberlich brothers, of Appleton. It is likely that the capital, which now is $6,000, will be increased to $200,000 and possibly $250,000. Appleton capital will be heavily interested. The new name will probably be the Eagle Automobile Manufacturing Company, and the product will be known as the "Eagle." It is planned to build two types of cars, a four-cylinder of 30 horsepower selling at $2,000 and a 4-40 selling at $3,000. W. D. Legge, an engineer associated with the Tuttle Press Company, of Appleton, will have charge of the new industry. Mr. Legge is now preparing plans and specifications and designs for the car, and it is planned to have the first car completed by May 15. However, the plant will probably not be in shape to begin actual production before June 1. Every part of the car will be built at Appleton.

Fig. 2—L. H. Kittridge, President Peerless Motor Car Company, Cleveland, O.

A Sacramento (Cal.) man who runs a stage line between that city and Folsom solved the problem of carrying an increased number of passengers, without overloading his car or tires, in an original way. As the illustration shows, he took one car and attached the back part of another to the rear axle. Thus he was able to carry practically twice as many passengers as before at the same expense. The car is equipped with Morgan & Wright tires, and he reports that the car has been running between the two cities 4,500 miles a month for the past three months, 13,500 miles in all, with absolutely no trouble from either car or tires.

The automobile factory of Besserdich & Zachow, at Clintonville, Wis., producing a new type of four-wheel drive car, will probably move to Appleton, Wis. The Merchants' Association of Appleton has offered strong inducements, especially in a financial way, which are expected to lead to the reorganization of the concern to include Appleton capital and to engage in the production of the car on a large scale. The probable capital will be $50,000. The car is the invention of William Besserdich, formerly of Appleton.

G. A. Maisland, representing the Ingram-Richardson Manufacturing Co., of Beaver Falls, Mass., says the Syracuse Automobile Club inaugurated in this State the movement to place danger signs and railroad crossing warnings. He came here to renew his contract with the Syracuse Club for 1910 signs, and was heard to remark at the club's offices that his contract with the Syracuse Club for last season was the means of inducing many other clubs to place such danger signs along the roads.

The Abresch-Cramer Auto Truck Company has been incorporated in Milwaukee, Wis., with a capital stock of $20,000. The incorporators are Charles Abresch, Robert Crawley and L. Schneller. Charles Abresch is at the head of the Charles Abresch Company, 398 Fourth street, Milwaukee, which has been manufacturing wagons and carriages and now devotes most of its time to building bodies and a line of commercial vehicles.

At Los Angeles, Cal., the Moline Car recently made a "mile-a-minute" record on the motorcycle saucer track.

PROMINENT ACCESSORIES

Quite a little attention is being paid to aeroplane work by the Livingston Radiator & Mfg. Co., of West Fifty-second street, New York City. The Livingston radiator is particularly adapted to aeroplane work because of its extreme lightness of construction, great strength, high efficiency and small resistance to the air. The only difference between the aeroplane radiator and the automobile radiator is the style and size, the principle being identical in every case. By using a design that is a great improvement on the square-tube radiator, it has been found possible to produce a cooling device showing 100 per cent. increase of direct radiating surface in contact with the circulating water. In fact, the circulation is equal both perpendicularly and laterally, through the cooling tubes, and at no time is there dead water in any portion of the radiator. Equal circulation through all the tubes is secured by the square corrugations. The combined area of the water passages is over 15 square inches, equal to the discharge of a pipe 4 1-2 inches in diameter.

These features, together with the fact that there are 64 square inches of radiating surface in direct contact with the circulating water for every square inch of frontal area, makes the radiator an extremely efficient one.

Patented lapped seams on all edges with the patented tubes increase the strength enormously and permit a pressure of over 30 pounds to the square inch, without any danger of leaks.

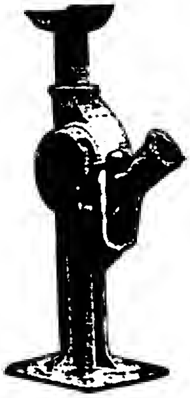
The resistance to the air is reduced by the patented swaged edges, which form the water passages without the use of space wires, thus saving weight and reducing the amount of solder used. The edges form sharp funnel-shaped entrances to the air passages, so that the radiator completed offers only one-sixth of the total area as resistance to the air, whereas in most cases one-half or more of the total area is offered as resistance to the air.

Throughout the entire construction the idea of great stability is never lost sight of. The radiating section and the frame are built complete in themselves and then assembled. All joints in the frame are made with long overlaps, reinforced with special pieces of the correct shape on the inside. Even the brackets are riveted fast and covered on the inside with an extra sheet of metal so that no leak could occur even though a rivet might tear loose.

The sides of the radiators are blocked off thus forcing the water to pass through the radiating section instead of down the sides.

Although the company did not begin active operations until October of this year it has already placed contracts with several concerns. Of course the aeroplane work will not be so heavy at first, but even this phase of the project is attracting considerable attention.

Among the novelties recently imported from Europe by Chas. E. Miller, the jobber, of 97 Reade street, New York City, is the "Radium" illuminated dial watch, on which the time of night can be distinctly seen in pitch darkness. This watch, it is believed, will be found of great interest to the public in general and to automobilists in particular. The hour divisions on the dial are indicated by dots of a luminous substance, and the hour and minute hands have a narrow line of the same substance imbedded in them. It might be thought that some difficulty would be experienced in reading the time without the usual numbers at the hour divisions, but it has been demonstrated by psychologists that these are not really necessary, for the reason that no one really looks at them. This is proved by the numerous advertising clocks which have letters, forming a name, instead of the numbers. In practice it has been found that it is as easy to read the time from this illuminated dial watch in the dark as from an ordinary watch in the light.



"A.B.C." jack, of the ratchet type.

The watch has also an alarm attachment, that they may be set at any desired time as usual. It has an "Anchor" movement. A special brass case is furnished for the attachment of the watch to the dashboard of an automobile. The case is fastened with a plug lock, which permits of the watch being removed only on the use of a special key.

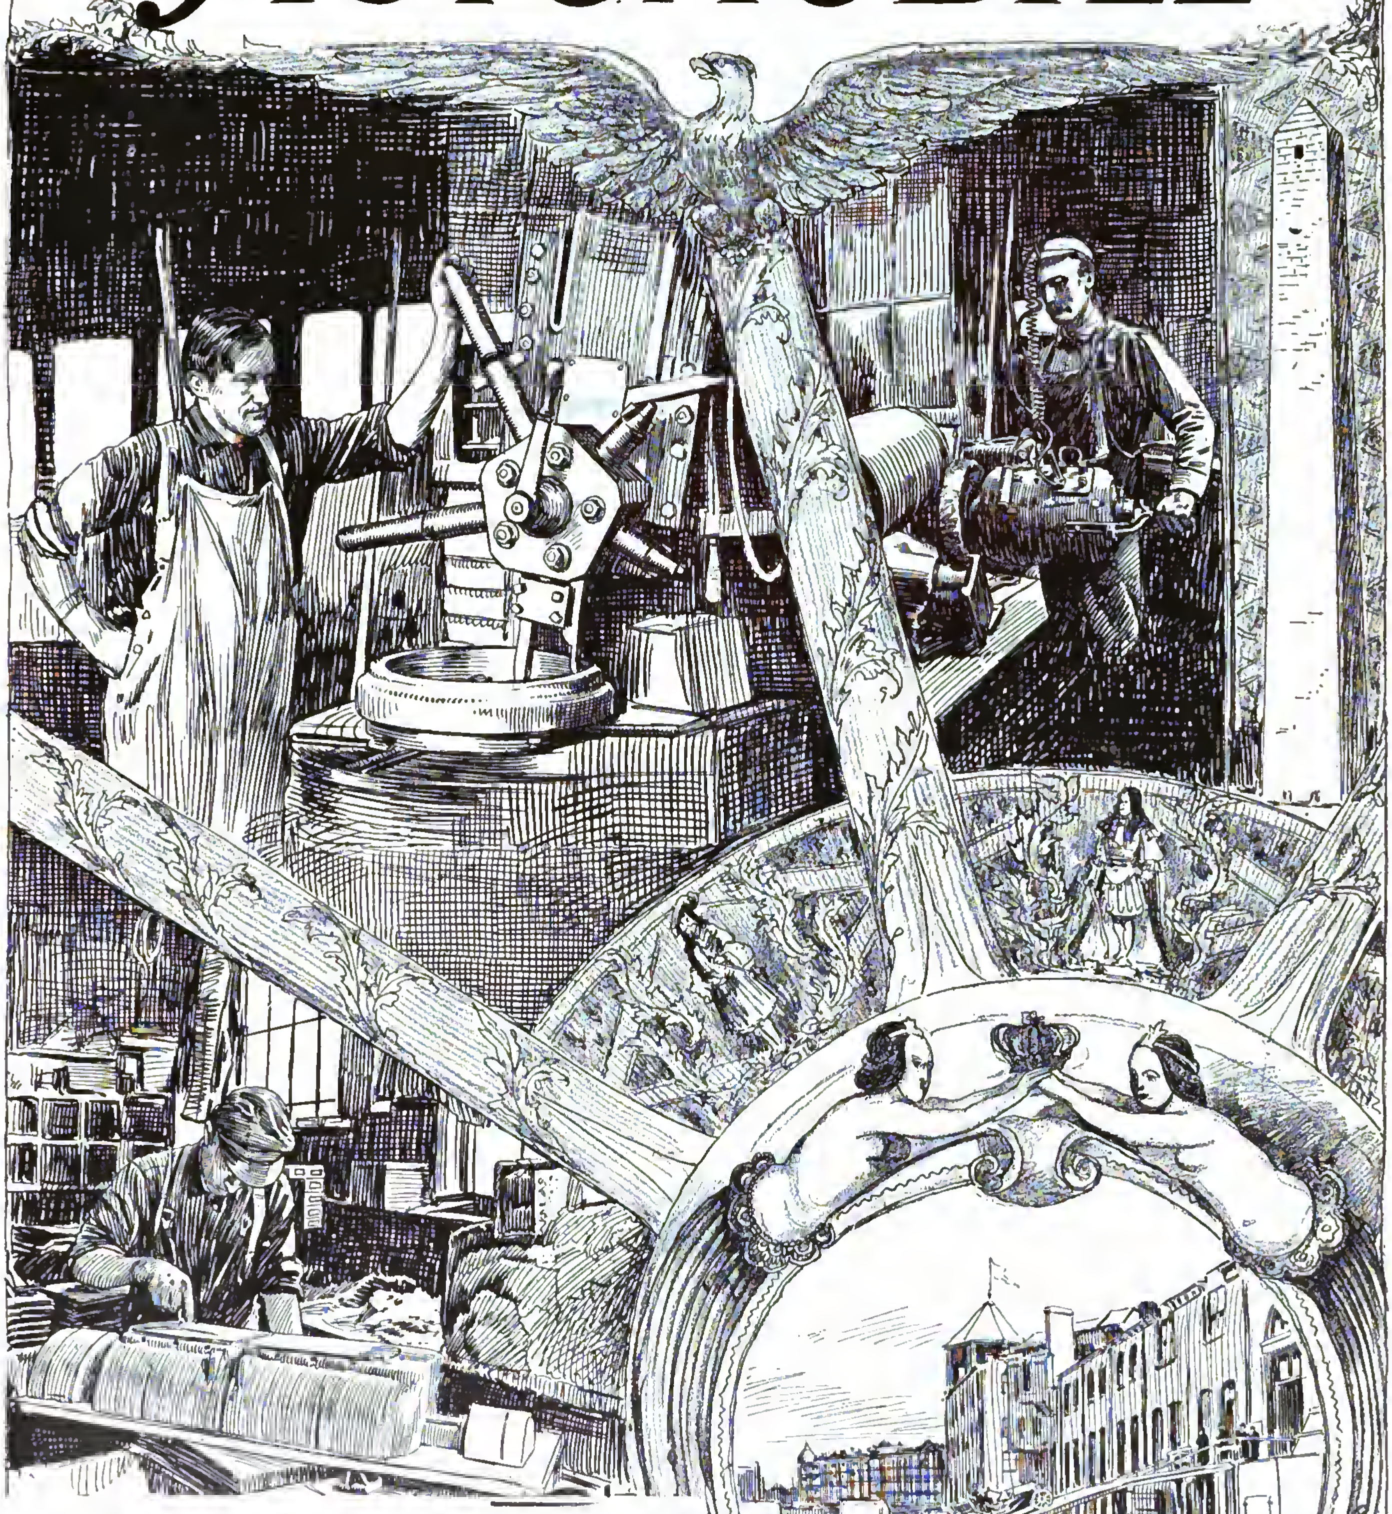
The A. B. C. Jack Company, 14 Columbus avenue, Boston, has put on the market the "A. B. C" jack, which sells at a moderate price, and embodies many distinct improvements over the ordinary type. The jack has a ratchet movement, with a separate lever handle. By a special device the handle is locked, so that it is impossible for it to come out while the jack is in operation. The parts are few and interchangeable. The movement is single action, controlled by a small lever projecting from the frame.

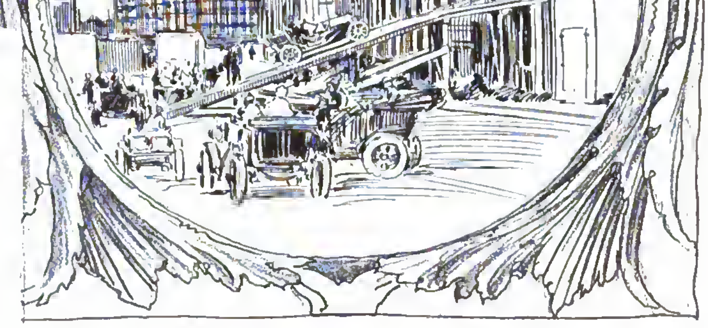
In appearance the jack is simple and neat, all the mechanism being enclosed; the only projecting part is the reversing handle. The base is ample in size, and on the whole easy and powerful action seems to have been combined with light weight.

Windsor T. White, president of the White Company, one of the family who revolutionized the steam automobile industry

Vol. XXII New York—Thursday, March 3, 1910—Chicago No. 9

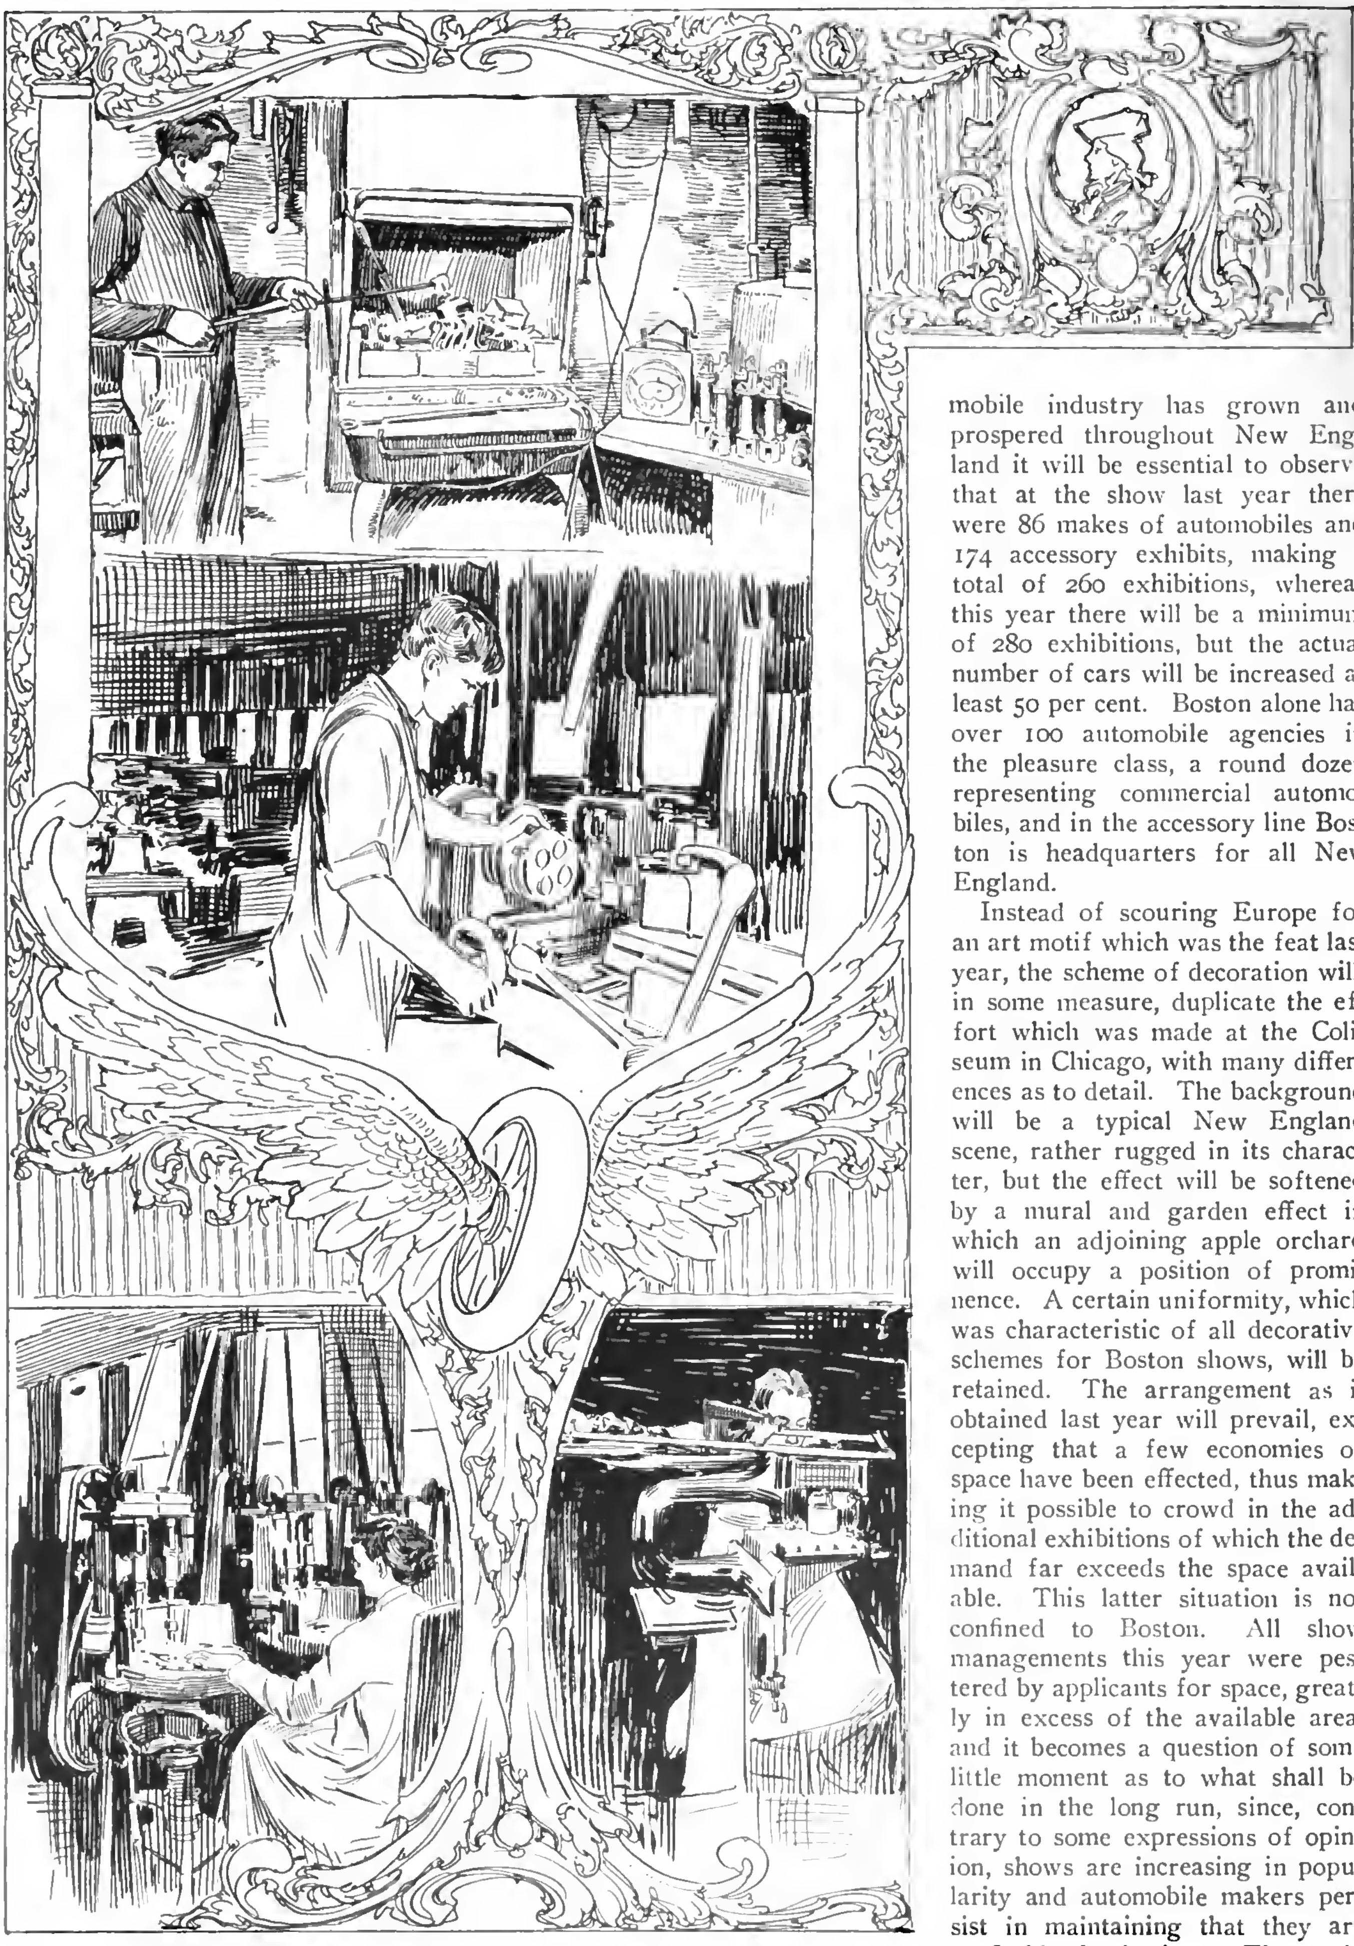
The Automobile





EXHIBITORS ARE GATHERING AT MECHANICS' HALL

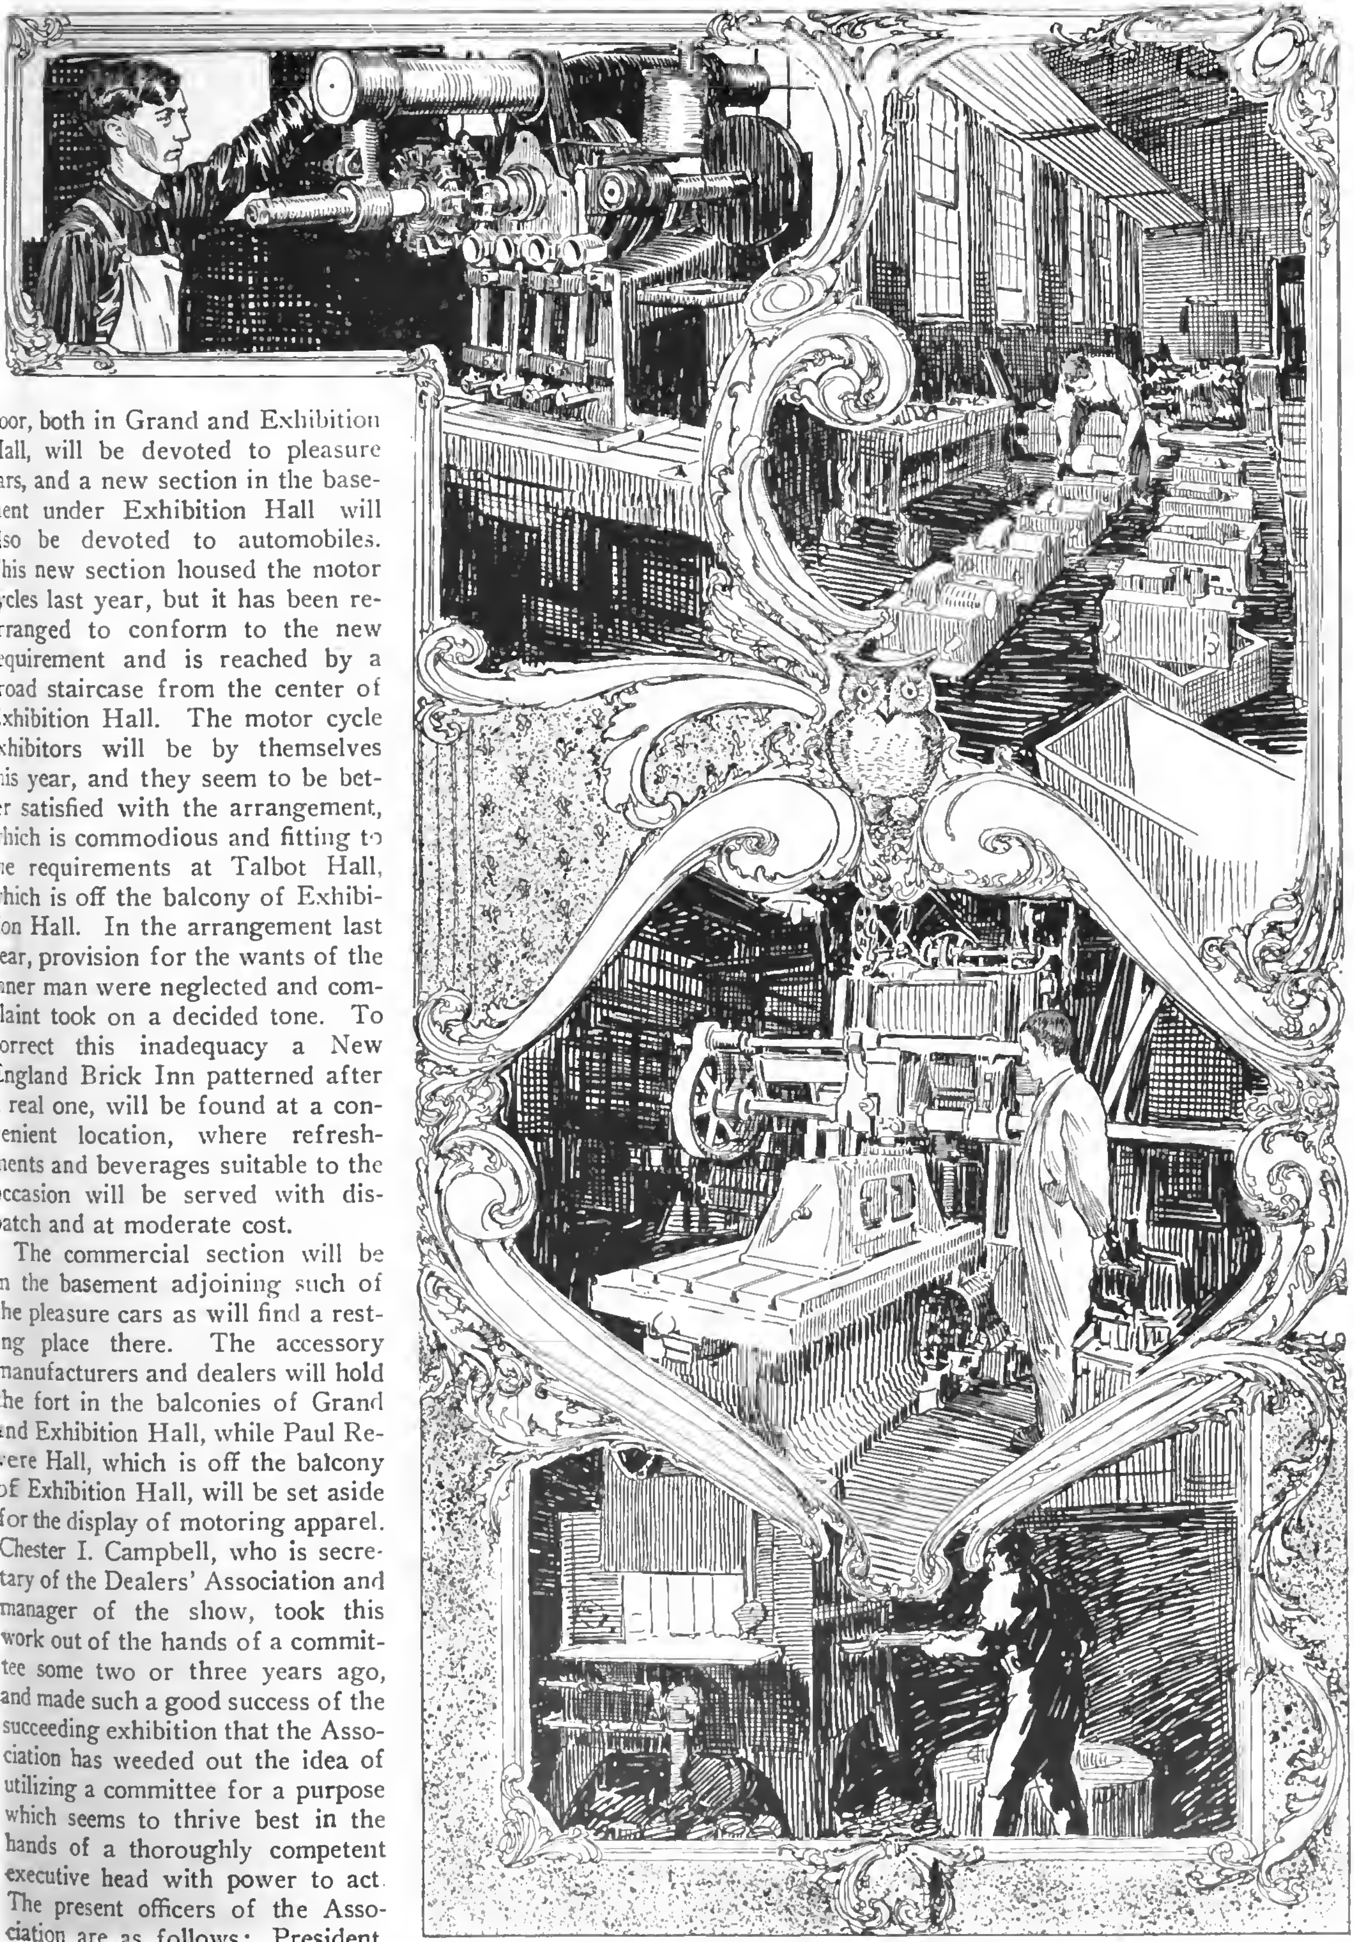
BOSTON will enjoy another automobile show which will open at Mechanics' Building on March 5, to run for 7 days, and will be known as the Eighth Annual event of this character. The undertaking will be under the auspices of the Automobile Dealers' Association, and under the direction of Chester I. Campbell, general manager, whom, it will be remembered, was directly responsible for the splendid success of last year's event. **In order to fully understand just how the auto-**



DYNAMIC ABILITY IS INDUCED BY PROPER HEAT TREATMENT

mobile industry has grown and prospered throughout New England it will be essential to observe that at the show last year there were 86 makes of automobiles and 174 accessory exhibits, making a total of 260 exhibitions, whereas this year there will be a minimum of 280 exhibitions, but the actual number of cars will be increased at least 50 per cent. Boston alone has over 100 automobile agencies in the pleasure class, a round dozen representing commercial automobiles, and in the accessory line Boston is headquarters for all New England.

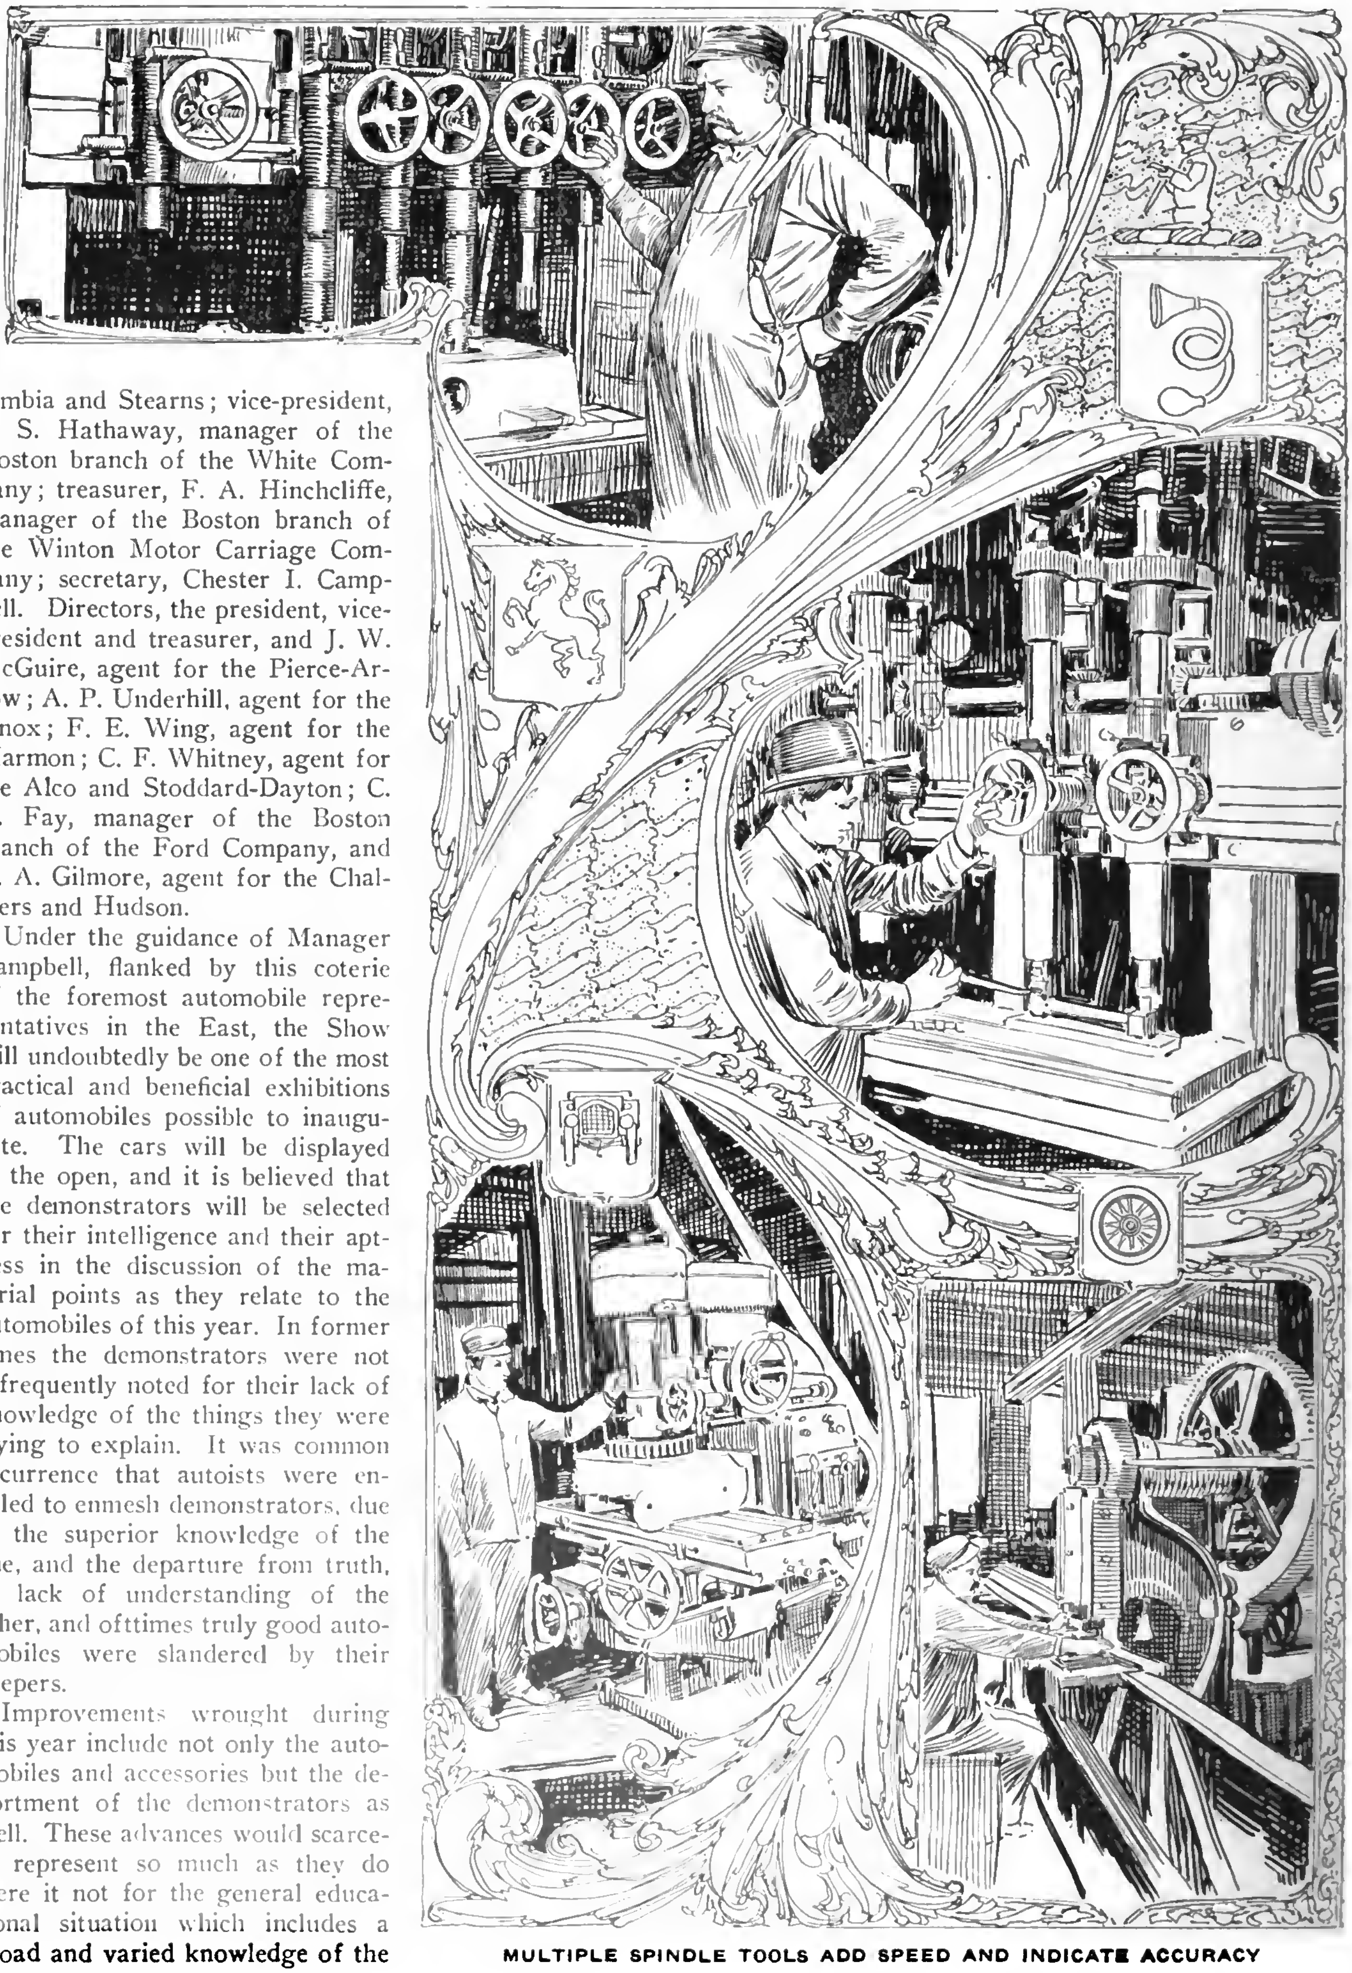
Instead of scouring Europe for an art motif which was the feat last year, the scheme of decoration will, in some measure, duplicate the effort which was made at the Coliseum in Chicago, with many differences as to detail. The background will be a typical New England scene, rather rugged in its character, but the effect will be softened by a mural and garden effect in which an adjoining apple orchard will occupy a position of prominence. A certain uniformity, which was characteristic of all decorative schemes for Boston shows, will be retained. The arrangement as it obtained last year will prevail, excepting that a few economies of space have been effected, thus making it possible to crowd in the additional exhibitions of which the demand far exceeds the space available. This latter situation is not confined to Boston. All show managements this year were pestered by applicants for space, greatly in excess of the available area, and it becomes a question of some little moment as to what shall be done in the long run, since, contrary to some expressions of opinion, shows are increasing in popularity and automobile makers persist in maintaining that they are **profitable institutions. The main**



floor, both in Grand and Exhibition Hall, will be devoted to pleasure cars, and a new section in the basement under Exhibition Hall will also be devoted to automobiles. This new section housed the motor cycles last year, but it has been rearranged to conform to the new requirement and is reached by a broad staircase from the center of Exhibition Hall. The motor cycle exhibitors will be by themselves this year, and they seem to be better satisfied with the arrangement, which is commodious and fitting to the requirements at Talbot Hall, which is off the balcony of Exhibition Hall. In the arrangement last year, provision for the wants of the inner man were neglected and complaint took on a decided tone. To correct this inadequacy a New England Brick Inn patterned after a real one, will be found at a convenient location, where refreshments and beverages suitable to the occasion will be served with dispatch and at moderate cost.

The commercial section will be in the basement adjoining such of the pleasure cars as will find a resting place there. The accessory manufacturers and dealers will hold the fort in the balconies of Grand and Exhibition Hall, while Paul Revere Hall, which is off the balcony of Exhibition Hall, will be set aside for the display of motoring apparel. Chester I. Campbell, who is secretary of the Dealers' Association and manager of the show, took this work out of the hands of a committee some two or three years ago, and made such a good success of the succeeding exhibition that the Association has weeded out the idea of utilizing a committee for a purpose which seems to thrive best in the hands of a thoroughly competent executive head with power to act. The present officers of the Association are as follows: President, J. H. MacAlman, agent for the Co-

FOUNDRY METHODS ADVANCED TO AUTOMOBILE REQUIREMENTS



lumbia and Stearns; vice-president, J. S. Hathaway, manager of the Boston branch of the White Company; treasurer, F. A. Hinchcliffe, manager of the Boston branch of the Winton Motor Carriage Company; secretary, Chester I. Campbell. Directors, the president, vice-president and treasurer, and J. W. McGuire, agent for the Pierce-Arrow; A. P. Underhill, agent for the Knox; F. E. Wing, agent for the Marmon; C. F. Whitney, agent for the Alco and Stoddard-Dayton; C. E. Fay, manager of the Boston branch of the Ford Company, and E. A. Gilmore, agent for the Chalmers and Hudson.

Under the guidance of Manager Campbell, flanked by this coterie of the foremost automobile representatives in the East, the Show will undoubtedly be one of the most practical and beneficial exhibitions of automobiles possible to inaugurate. The cars will be displayed in the open, and it is believed that the demonstrators will be selected for their intelligence and their aptness in the discussion of the material points as they relate to the automobiles of this year. In former times the demonstrators were not infrequently noted for their lack of knowledge of the things they were trying to explain. It was common occurrence that autoists were enabled to enmesh demonstrators, due to the superior knowledge of the one, and the departure from truth, or lack of understanding of the other, and ofttimes truly good automobiles were slandered by their keepers.

Improvements wrought during this year include not only the automobiles and accessories but the deportment of the demonstrators as well. These advances would scarcely represent so much as they do were it not for the general educational situation which includes a broad and varied knowledge of the

GRINDING PROCESSES REDUCE LIMITS OF TOLERANCE

mechanical intricacies of the automobile on the part of the autoing public. In former times, prospective purchasers of automobiles were wont to attach their faith to apparently nice selling points, but they have learned the story over again, which is so aptly put in the paraphrase, "one swallow does not make a summer."

What they expect to find in the 1910 automobile situation is noiseless performance, interchangeability, a certain get-at-able-ness, and the facility which will enable them to overhaul the automobiles without having to use a variety of special wrenches which are so prone to stray away and leave one in the lurch by the roadside, distant from a repair shop.

Despite the apparently critical attitude of the patrons, it is believed that they will be more sensible and tolerant, but they will not exhibit the rare quality which was once present in a King of Spain who thought that if he had the making of the world he could have done it better. It is now common belief that the automobile is sufficiently near a conventional state in point of design so that buyers will hardly have to inflict their ideals upon the makers, and they will confine themselves during selection to the questions which will be reflected by their own needs.

There is a little curiosity expressed among autoists in general bearing upon the attitude which the New England will assume in relation to torpedo body work and a few of the other ideas which dominate the present situation. So far this type of body has received favorable comment and it is claimed by makers that it is here to stay. Mechanically, the situation is less likely to be judged as otherwise than favorable, since the changes are less radical following along defined lines well executed.

CHESTER I. CAMPBELL

New England, as the home of the Industrial Arts, becomes the court of last resort, and the makers of automobiles display wisdom in its serenest form, when they bring the best of their wares and lay them down in Mechanics' Hall to be judged. That they will be critically examined and passed upon in accordance with their respective merits, to the prejudice of none, is a conclusion which it is safe to draw, and which is reflected in the every day life as it is viewed in perspective.

It will be important to the exhibitors to make their representations in conservative and fitting language. They will find the audience intelligently critical, observing, and tolerant. They will want to know the reasons why the innovations are given a resting place instead of contrivances which may have served them faithfully, and they will look for accessibility as they never did before. The makers have had their say, and they promised interchangeability in the automobiles of the year. The Boston autoist, instead of reflecting the characteristics of the man from Missouri who wants to be shown, will look for himself, and his experience will be sufficient for his wants.

It is confidentially expected that the Boston critic will find many things to satisfy him among the new automobiles and the many phases of the accessory situation. The materials employed this year are the result of long deliberation and have been reduced to a standard at the behest of engineers of skill and discrimination. The machining processes are the direct result of automobile engineering in its most advanced form, some of the most capable of which have been suggested here in sketches taken from life, with the avowed object of hinting to buyers something of the underlying situation.

EXHIBITORS

Fiat Repair Co., 199 Berkeley St.	309
Firestone Tire & Rubber Co., Akron, O.	506, 507
Fisk Rubber Co., The, Chicopee Falls, Mass.	436
Flentje, Ernest, Cambridge, Mass.	532AA
Forbes, W. J., 70 Long Wharf	620

Looking Ahead
in the
Automobile Industry

CONTEMPLATION of the future prospects and possible growth of the automobile industry is an occupation fraught with considerable danger; no other product of man's ingenuity has shown such a perverse tendency to confound all would-be critics. An example of this disposition will be afforded by a glance at the statistics of the industry printed in these columns but four weeks ago. In the article referred to tables were given of all the known companies engaged in manufacturing automobiles; the list totaled 211 names. In the four weeks following no less than 23 additional firms—more than 10 per cent—have been added to the ranks.

At the same time the total number of cars to be produced in this country during 1910 was estimated at 280,000, and at the time this seemed hardly a conservative figure. Since that time a great number of firms have increased their figures, and with the added product of the newcomers, it is inevitable that the total will run well over the 300,000 mark.

The standings of the various cities and States as centers of the industry have been considerably changed by these additions. Milwaukee, Wis., has been the scene of the greatest activity; it has, since the compilation of the last set of tables, acquired four companies manufacturing motor trucks and other commercial cars. These place it sixth in the list of cities ranked according to the number of firms, with a total roll-call of seven. St. Louis has been moved up to fifth by the acquisition of three new firms, one manufacturing pleasure cars and one both pleasure and commercial vehicles, which make its present total eight.

Chicago has become the home of three new companies, one for the production of pleasure cars and two for commercials, which give it a total of eleven and advance it to second place, ahead of Cleveland and Indianapolis, and second only to Detroit. This last city has had its roll increased by two, one making pleasure and one commercial cars, so that its number of factories now attains the comfortable figure of 25. Minneapolis, Minn., also has shown some activity, and has obtained two new plants.

AMERICAN PRODUCTION BY YEARS
What May Be Expected from Continued Increase

		Cars Produced	In Use
Figures known approximately	1907....	80,000	100,000
	1908....	130,000	200,000
	1909....	200,000	350,000
	1910....	300,000	600,000
Figures based on 50 per cent annual increase	1911....	450,000	1,000,000
	1912....	675,000	1,600,000
	1913....	1,012,000	2,500,000
	1914....	1,519,000	3,800,000
	1915....	2,278,000	5,900,000

During the past three or four years the number of automobiles produced in the United States has increased each successive year by some 50 per cent over the preceding year. The number for 1909 was in the neighborhood of 200,000; for 1910 it will inevitably exceed 300,000. Carrying on this line of thought, it is interesting to see just where this rate of increase, if constantly maintained, would land the industry. With an increase of 50 per cent over the 300,000 for 1910, 1911 should see 450,000 cars brought forth; for 1912 the figure would be 675,000, for 1913, 1,012,000, and so on.

Five years is a very reasonable expectation of life for a modern automobile; there are plenty of cars of the vintage of 1904 in every-day use at the persent time. On this basis, and assuming the rate of progress outlined above, the end of the year 1913 would find a total of 2,637,000 cars in use!

At first this sounds like the wildest speculation; but perhaps these figures will repay a short consideration. How many automobiles can the population of the United States use? There are many possibilities in such an inquiry.

It is a matter of common knowledge that there are in use in the United States at the present time more than 300,000 automobiles, and the demand still seems almost unlimited. When the additional 300,000 to be made this year are included, it will be seen that at the close of 1910 one person out of every 150 in the country will have an automobile, or one family out of every forty or fifty. Obviously the number of families capable of maintaining an automobile is comparatively limited, although the average is brought up by some who are able to support two or more. One family out of twenty seems about the ultimate limit, even considering the utmost possibilities of the $500 car.

The population of the country is increasing pretty rapidly, but not in a proportion to keep pace with the automobile product. Some time in the latter part of 1912, when, according to the schedule outlined above, there will be roughly a million and a half automobiles in use, the limiting ratio of one car to every 70 persons will be reached.

At that time the $500 car will have reached its perfection. With the great increase in the number of cars manufactured, and the consequent reduction in overhead charges and cost of material, the cars selling at that price will probably be very nearly what we now pay from $750 to $1,000 for. Barring the possibility of radical changes in design, it should be possible at that price to put on the market a four-cylinder car of 20 or 25 horsepower, seating four or five persons, with a wheelbase of not less than 100 inches, and 32 or 34-inch tires; these cars to be made in series of not less than 50,000.

When the million-and-a-half mark has been reached, this will imply the owning of a car on every farm of even moderate size, and by most of the salaried workers in the country. But private ownership and use, albeit largely for purposes commercial in their nature, is but the smaller part of the usefulness of the automobile. Some indication of the trend which the industry is now taking may be had from statistics of the 23 firms mentioned above as the latest comers in the field. Of these, 10 make pleasure cars, 11 make commercial cars, and two make both pleasure and commercial models. In the list previously published were enumerated 176 makers of pleasure cars, 22 who made both, and 24 who made commercial cars exclusively. The addition to the commercial ranks is nearly 50 per cent., that to the pleasure car makers less than 6 per cent. Thus is indicated the turning of the tide.

In all branches of commercial vehicle work the progress made so far has been only sufficient to give some view of the immense field ahead. From the lightest 500-pound delivery wagon to the 10-ton coal truck there is an immense range of possibilities. The comparatively few commercial vehicles in operation now have been sufficient to prove the economies of this method over the old-fashioned horse-drawn vehicles. During the four years which we have in prospect the greatest advances will be made in this line.

In several classes the automobile has already made notable inroads into the province of the horse. Most of the large department stores in New York, Chicago, and other large cities have discarded their horse-drawn delivery wagons, and have adopted motor vehicles instead. In brewery trucking motor power is almost supreme, and in the conveyance in large quantities of groceries and miscellaneous merchandise it has become prominent. Most conspicuous of all is the taxicab, which in the space of three years has practically put horse cabs out of business in all the large cities.

Newspapers find the automobile invaluable as a means of conveying their editions to outlying distributing stations. When the crowds leave the Harvard Stadium after a football game, they are met at the gates by newsboys with Boston papers from presses five miles distant, giving practically complete the details of the game and the final score—thanks to automobile delivery service.

With the lone exception of the Fifth avenue and Riverside Drive busses in New York, this country has nothing to compare with the innumerable bus lines in London, Paris and other large European cities. Certainly they are needed, and they will come. The 'bus line has every advantage over the trolley for infrequent service, and proves a formidable competitor even under "rush" conditions. For suburban and country service the next few years will find them supreme.

Further developments may be forecasted with some degree of accuracy. Automobile delivery service is sure to become universal; now used only by companies who must maintain extensive establishments, and by a few smaller concerns for advertising purposes, it will gradually spread among all classes. Great numbers of light delivery wagons with two-cylinder motors of moderate power, especially adapted to this service, will be produced this year.

In the truckage field the prospects are equally bright. Manufacturing plants, large retailing and wholesale merchandise houses, and dealers in coal and building materials will find motor service quicker, surer and more economical than horse service. Those concerns will especially benefit whose business requires the transporting of heavy goods between factories or distributing points twenty or more miles distant. All sorts of express and mail delivery will be done by motor power.

An important development in this connection will doubtless be the appearance of companies which will rent automobile trucks and delivery wagons on a service basis. The renting companies will own their own machines, a hundred or more in number; will maintain their own garages, do their own repairing and hire their own drivers. The companies who buy the service will do so simply on a mileage or ton-mileage rate, or on a basis of the number of deliveries made, according to agreement; they will buy a definite service and incur no risk beyond.

As feeders for railroad and interurban electric lines automobiles are already of great utility. Many farmers are finding that they can combine in one car a pleasure vehicle for family use, a swift runabout for business purposes and a light wagon for carrying fruit, vegetables and milk to the railroad station. The enormous spread of the good roads movement is constantly broadening the possibilities in this field.

When all these spheres of activity are considered, the number of automobiles which it is possible for the people of the United States to buy and make use of seems to enlarge almost beyond limits. With every delivery wagon, truck, farm wagon, cab and omnibus replaced by an automobile, it is easy to see the possibility of absorbing the two million or more cars of the estimated production by 1913.

The benefits of the change will be far-reaching. The primary reason for the adoption of the automobile in all the cases cited is its economy over present methods, whether in money or what is just as important, time. With automobile service universal, the economy may even be extensive enough to make a reduction in the "cost of living," now such a prolific source of discussion. Although the automobile has been the cause of many jokes on the mortgaging of homes, and is regarded in some quarters as a sign of reckless extravagance and profligacy, innumerable business men will vouch for its usefulness. Truer than ever before is the saying that transportation is civilization.

In cities the use of automobile trucks and delivery wagons will solve the traffic problem. Although traffic as a whole is able to move faster than its slowest members, it is nevertheless considerably impeded by them. Moreover, the adoption of the automobile means the saving of the space formerly occupied by the horses, in many cases amounting to half the total length of the vehicle. With each individual vehicle only taking up half the space that it formerly did, and moving at twice the speed, it is plain that there will be four times as much room. Increased speed, even in cities, is by no means necessarily dangerous to the public. With proper traffic regulation, the greater speed means ample time for crossing in each direction at street intersections, at the same time without causing undue congestion.

The advantage to public health resulting from the disappearance of horses and their accompanying pests, the livery stables, will be inestimable. Street dust is a prolific breeding place for germs of every kind; its noxious effects are recognized by physicians. The passing of the horse means no more dust, and a consequent saving to municipal street-cleaning departments. These advantages will be recognized more and more with time, and in 1913, with the speculative two millions of automobiles in operation, it will not be a cause of surprise if all large cities will have passed laws prohibiting the keeping or use of horses within their limits, save perhaps for driving or riding in certain specified parks and boulevards.

One more consideration—these estimates have been made without considering the export possibilities, which are sure to be developed much more than at present. Although the field for automobiles in all Europe is perhaps not so large as in the United States alone, it is nevertheless of very considerable size, and the home factories are not only incapable of caring for it, but show no inclination to expand in order to do so. Quite possibly another million cars may be absorbed by the European market, at present developing rapidly.

ESTIMATED PRODUCTION BY STATES

States	Cars	Value
Michigan	160,000	$205,000,000
Ohio	45,000	66,000,000
Indiana	38,000	55,000,000
New York	12,500	40,000,000
Illinois	11,000	17,000,000
Wisconsin	10,000	14,000,000
Pennsylvania	7,000	12,000,000
Connecticut	4,000	12,000,000
Scattered	15,500	29,000,000
Total	303,000	$450,000,000

Mechanical Details of New England's Product

CONSERVATISM, which is said to dominate all of the actions of New England folks, need not of a necessity be applied to the automobile manufacturers located in that flourishing part of the country. These makers, though rather few in number, compare favorably with those from any other section in progress, both in larger matters and in the small niceties of detail.

The parts shown elsewhere on these pages show this and if further proof be needed some brief description will be added, this dealing more particularly with some one feature of each car, rather than attempting to describe the car as a whole. This scheme will have the advantage of accenting the more notable details of construction, to which every maker is pledged in one form or another, as well as supplying at the same time much real and practical information.

With perhaps a single notable exception, no one feature is more notable than that of uniformly high or medium prices, that is to say, there are few if any very low-priced cars made in New England. As to features, all of them are represented, including chain drive, two-cycle engine, air-cooled engines, steamers, wire wheels, electrics, commercials one, two three four and six cylinders unit power plants, valves in pockets and in the head, two, three and four speed transmissions, and many more minor features. In short, taking the cars as a whole, they run the whole gamut of motor car parts, both as to design, methods of construction and assembling and manufacturing methods.

This is, of course, to be expected, and probably, or at least, possibly, would be true of any other section of the country, which might be picked out, and its product analysed. Of all the features listed, steam has long been thought to have its home exclusively in New England, but latter day statistics show this idea to be fallacious, the increased output of Ohio, Michigan and Illinois factories devoted to this branch, coupled with the decreased activity of some Bay Staters in this line, having shifted the geographical center, so to speak, so much farther West that it passes out of the western boundaries of New England proper.

Alco Adopts Shaft Drive Entirely

With the announcement of the season's models it was noted that the Alco has now definitely abandoned the chain drive for its own system of shaft drive, in which the load-supporting member of the rear axle is a solid drop-forging. This drive has been thoroughly tested in the Alco town cars and taxicabs, in which it has been always used, and its adoption in the larger models is in no way remarkable. Another important change is the adoption of the Bosch dual system of high-tension ignition, which includes a storage battery with the magneto, although both work on the same set of plugs. The use of the battery enables the motor to be started on the spark. These are the chief changes; they are in conformance with the policy of the company to Americanize the French design of the Alco in order to meet the prevailing demand. The company emphasizes the fact, however, that never is any change made until it is certain that the quality and all the distinctive character can be maintained.

Rakish Knox "Sportabout," a Product of the Springfield, Mass., Factory

Most of the excellent features have been retained, and each one of these is a reason for buying in itself. The special design of rear axle of the full floating type, the French type of engine, Americanized, the anti-fatigue steel used throughout the car regardless of cost, the unusually large and powerful brakes, the deep, square tube radiator and other features which space prevents the mention of, are all mute but eloquent arguments in favor of the Alco car. With these changes goes a considerable reduction of prices.

Turning to the table of standard American automobiles, as given in last week's The Automobile, it will be noted that the changes were such as to bring this car more close to the standard, the percentage of chain-driven models in their class, the $4,000 class, being but 8.1. So, too, with the change in ignition, although this percentage is but 10.4 it marks a tendency which is growing rapidly.

Cameron Line All Air Cooled.

Air as a means of cooling the cylinders of the engine seems to appeal to the makers of the Cameron cars, the Cameron Car Company, located at Beverly, Mass., and New London, Conn., since all models turned out are thus cooled. For this year both four-cylinder and six-cylinder models will be listed, with all styles of body, a distinctive engine, as well as transmission, while the prime idea of the whole construction is that of obtaining light weight without making any sacrifice in other ways.

Not only will two separate and distinct types, such as a four and a six, be built, but they will be manufactured in two separate and distinct factories, each devoted to a single style and type of car. This should result in each one being superior to what it would be if the two were made under the same roof. The fours are manufactured at the Beverly plant and comprise five models, including two-passenger runabout, special two-passenger featherweight flyer, three-passenger roadster, four-passenger surrey with detachable rear seat, and standard touring car. The prices range from $950 to $1,100. The sixes are manufactured in the new plant of the Cameron Company located at New London, Conn., and the line comprises five models as above, all listing at $1,500.

It has been the policy of the Cameron Car Company from the very earliest days of its existence in 1902 to manufacture its cars complete in its own works, and this policy is being pursued in exactly the same manner to-day. The four and six-cylinder cars are manufactured in separate plants which build, from the ground up, all parts which go into their

Knox Close-Coupled, Fully Equipped, Made in Springfield, Mass.

respective cars. Every detail is known to a certainty.

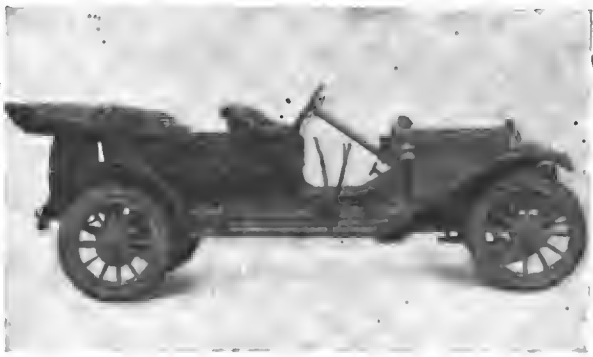
The motors for the coming season show no radical changes and are built along the lines on which Cameron has been working for the last seven years. Minor improvements will be found, but reference to the illustrations herewith will show that important features such as the system of air-cooling and location of valves remain the same as heretofore. The four-cylinder motor is 3 7-8 bore by 3 1-2 stroke, developing 24 horsepower, and the "Six" developing 36 horsepower. Both are regularly equipped with high-tension dual system of ignition, which inclues the magneto and auxiliary set of dry cells, gear pump, constant level oiling system of a very simple, effective design, oil being carried from a large chamber on the lower side of the engine base through a tell-tale on the dash and forced into the crankcase under a high pressure, where it is sprayed on shaft and connecting rod bearings. Thence it flows to the bottom of the case and lubrication is furnished to the cylinders by splash. The engine base is of aluminum, split horizontally in the center, the cylinders cast singly with radial fins.

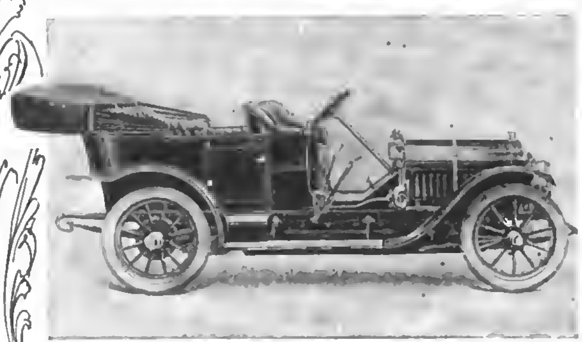
Clutch is a self-contained cone of proportionately large diameter and easy angle of contact. Engine bearings are of nickel babbitt; camshaft bearings, case-hardened steel set in cast-iron bushing, and crankshaft rocker arms and all important small parts are of drop forged nickel steel. The wrist pin construction of these motors is the same as has been used by Cameron for years and is slightly different from that known to general practice, the wrist pins being steel drawn tubes, hardened and ground, with a hardened and ground connecting rod swinging directly upon them with no bushings whatever, thus giving two round surfaces as a bearing. These will run almost indefinitely without showing any signs of wear whatever. It is claimed that this construction will outlast half a dozen bronze bushings.

The valve action is unusual. The valves are set in the cylinder heads opposite each other, with their stems horizontal. They are actuated by long rockers, one end of which bears on the cam and the other on the valve stem; no push rods are used.

SPECIAL REAR AXLE TRANSMISSION SYSTEM

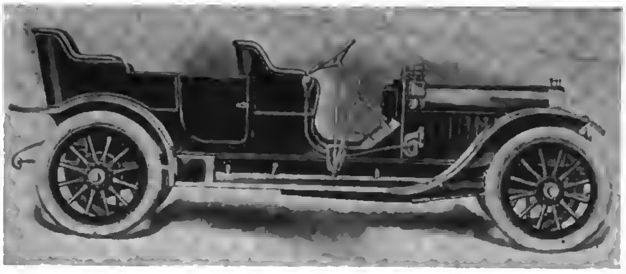
This is of the Cameron patented type, three speed selective, direct drive on all speeds. The six-cylinder system is slightly different from that used on the four-cylinder cars. This change will readily be understood by those who are familiar with the

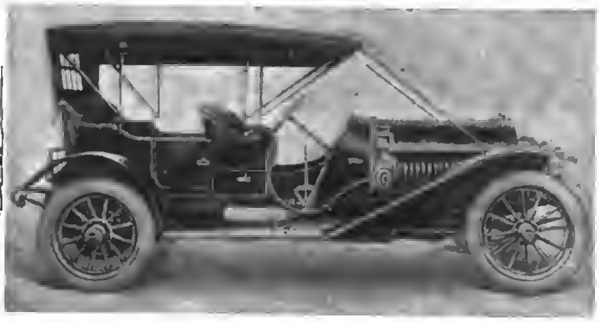


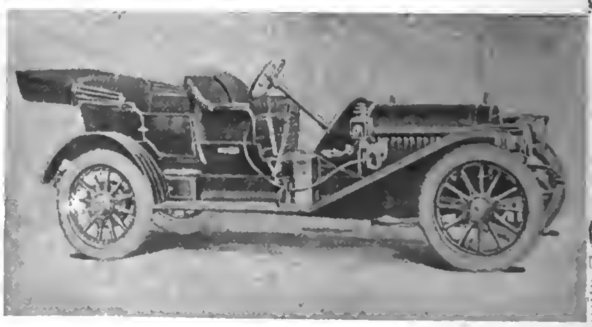


Top—The "Full Jeweled" Corbin from New Britain, Conn.
Bottom—Hartford, Conn., is the Home of the Pope-Hartford

transmission. On the lighter machines, that is, the four-cylinder line, the transmission carries three gears on the cross or jack-shaft and one on the differential, while on the heavier transmission used in the six-cylinder cars, two gears are carried on the cross-shaft and two on the differential. While all of the six-cylinder models weigh less than 1,700 pounds, still this car is slightly heavier than previous models, and with the great power of the motor, of course, requires a heavier gear all round than the four-cylinder cars. The power is delivered from the engine to the rear wheels through a single universal joint to driving shaft and bevel gears, to the cross or jack-shaft, and finally, from the cross-shaft by wide face spur gears to the rear







Top—Another from Springfield—the Two-Cycle Atlas
Middle—Alco, from Providence, R. I., as a Tourer
Bottom—Representative of the Locomobile Factory

axle. The advantage gained in this construction aside from the fact that the gears, instead of being thrown into mesh sideways, are thrown directly together face on and rolled together with a natural motion, is the fact that the bevel gears never receive more than the engine pull, and being set up firmly in mesh in a solid steel frame running on adjustable ball bearings, have no chance of springing out of mesh under heavy load or showing any undue wear, which always means much loss of power to a bevel gear.

In shifting gears, the arch carrying the gear set is first thrown forward in the case when the combination of gears wanted is thrown into line. When traveling crosswise in the case there is no strain against the gears to prevent sliding over. Gears are then brought together, face on, with a natural rolling motion which prevents jar, shock, or any injury to the gears themselves, as no strain of the engine pull can be put upon the driving gear until they are firmly in mesh and locked into position. The reverse gear stands idle except when in use, and is then thrown down in mesh from the top of the case. All gears are of unusually wide face and coarse pitch, are made up of drop forged blanks of chrome nickel steel, as are also the shafts. Ball bearings are used throughout the transmission and rear axle and are of annular type, of Cameron's own design and construction.

Refinement of Fine Car, Columbia

Close attention to the main details of the product will be the keynote of the Columbia production for 1910, the result being an ultra-refined Model 29. With the model first evolved in 1906 there has been opportunity to raise each unit of construction to a very high place and for the year at hand the new car will first interest veteran motorists for a number of little niceties which have been incorporated. Friends have said that it contains more clever features than any car of current building. Also, it is fair to state that no new car in its first or second year could have been worked out to a state of such high efficiency.

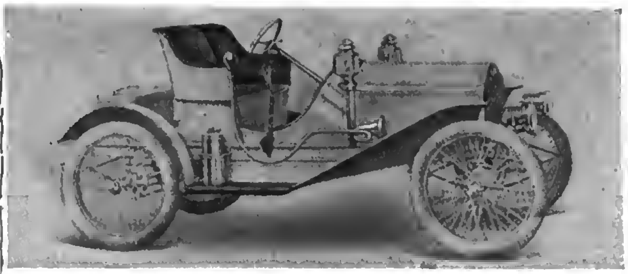
The company is building the car as well as Columbias have been built in the past, which means to a fine point of machining accuracy. Further it is provided with a higher quality of raw material than the market has ever previously held. These and what seems to be a fortunate selection of body styles have made for a strong interest in the car.

As to body style, the latest form which this takes is the short chassis with toy tonneau, double or single rumble. All three of these are interchangeable. This particular body is frequently done in a light gray, striped a lighter green, and upholstered in dark green. The whole effect is very attractive, as are also all of the other color tones, most of which show a tendency towards gray and the other, pleasing lighter colors.

BRIEF MENTION OF DETAILED CHANGES

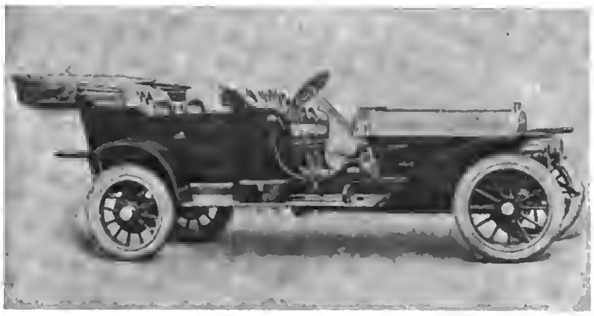
Considering the mechanical parts in detail of the model known as Mark 48, Lot 4, the bore and stroke, together with the dependent working parts of the engine have been increased in size. The valve springs are completely covered to exclude dirt and eliminate noise. The crank case is extended to enclose the front engine gears, so that the splash oiling system now lubricates these gears. The oil supply is carried in a compartment cast integral with the lower half of the crank case, a float indicator showing the amount on hand. The oil pump, driven by bevel gears from rear end of valve cam shaft, is located below the level of the supply, thus relieving it from drawing up the oil. The oil level in each compartment of the crank case is regulated by thumb screws, easily accessible from the outside. The governor is driven by bevel gear from rear end of cam shaft. A drain cock has been installed on the water pump. The float feed, multiple-jet carburetor has a hot water jacket surrounding each mixing chamber and an automatic air valve is added to the small barrel, resulting in a more uniform mixture. A square section intake pipe replaces the round pipe of preceding practice. The "Seeley" jump spark ignition system with separate set of plugs, introduced over the inlet valves is installed in addition to the regular make-and-break system, and takes current either from an "Exide" Storage Battery or "Bosch" low tension magneto, enabling one to start from the seat. The distributor for the jump spark system is driven by bevel gear from rear end of cam shaft. The engine starting ratchet is attached to the engine middle section instead of the frame, resulting in perfect alignment. The radiator of "Extended section type," is of increased size and provided with a rubber covered cap. It is swung on trunnion supports and therefore receives no strain from any frame movements or distortion.

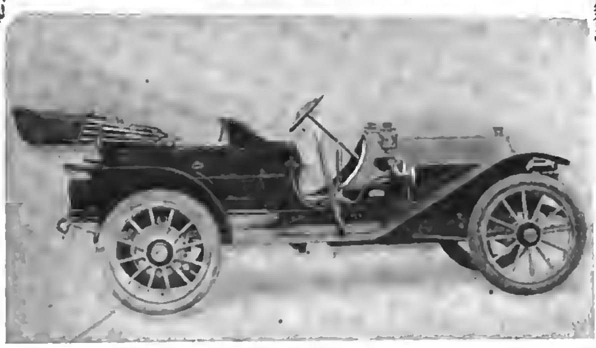
The fly-wheel rim markings are numbered in sequence to facilitate valve and ignition timing. The cone clutch is increased in diameter and the clutch shoe springs are made adjustable and self-locking. The universal joints on the propeller shaft are completely enclosed in grease retaining covers. The rear axle housing and all moving parts therein are increased in size in proportion to the increase of engine power. The braking surfaces on rear hub drums are greater and the contracting foot brake bands lined with "Thermoid." Clutch and brake foot pedals are of disappearing type, adjustable to any length of limb. All brake rods are adjusted by locking bar turnbuckles, eliminating the use of wrench or other tool. The foot pedal operating the large carbureter is set level with the floor to insure foot support and steady, easily applied pressure.



ELECTRICS, TOO, HAVE BEEN REFINED

In this day and age of the gasoline machine, it is interesting to note a maker giving almost equal attention to the electric. This is the exact situation of the Columbia concern, the electric vehicles having been made the recipient of as much study as the gasoline driven cars. The electrics are now made in two distinct models—a light Victoria-Phæton and a town carriage of the coach class, the first being well suited to the use of physicians and women and valuable for all purposes demanding a light, speedy conveyance for two persons. The leading features include divided Exide Hycap battery of 24 cells with its weight evenly distributed over both axles. improved type of motor, six speed continuous torque controller, two complete sets of brakes, each independent of the other, "Hess-Bright" ball bearings throughout, and thirty inch wheels fitted with Hartford quick detachable rims and tires.





Top—Metz, from Waltham, Mass., Sold Unassembled.
Middle—Stevens-Duryea, from Chicopee Falls, Mass.
Bottom—Four-cylinder Stevens-Duryea Baby Tonneau

The Columbia town carriage is provided with either a brougham or landaulet body, and for private service is unexcelled. In the construction, lightness has been obtained everywhere but nowhere at the expense of strength. Hartford pneumatic tires in combination with a most flexible form of spring suspension insure easy riding qualities never before attained in a vehicle of the coach type, either self-propelled or horse-drawn. Speeds ranging from 4 to 18 miles per hour are quickly and easily obtainable through a controller lever mounted upon the steering column within convenient reach of the driver. Two powerful, independently operated brakes, and a safety switch insure absolute certainty of control under all conditions of street traffic. The special Exide battery is the most efficient and reliable yet devised for vehicle use. There are inside seats for five persons. The upholstering, interior fittings and appointments are of the finest materials obtainable and the entire finish down to the smallest detail is of the most elegant.

Finances Favorable for Corbin

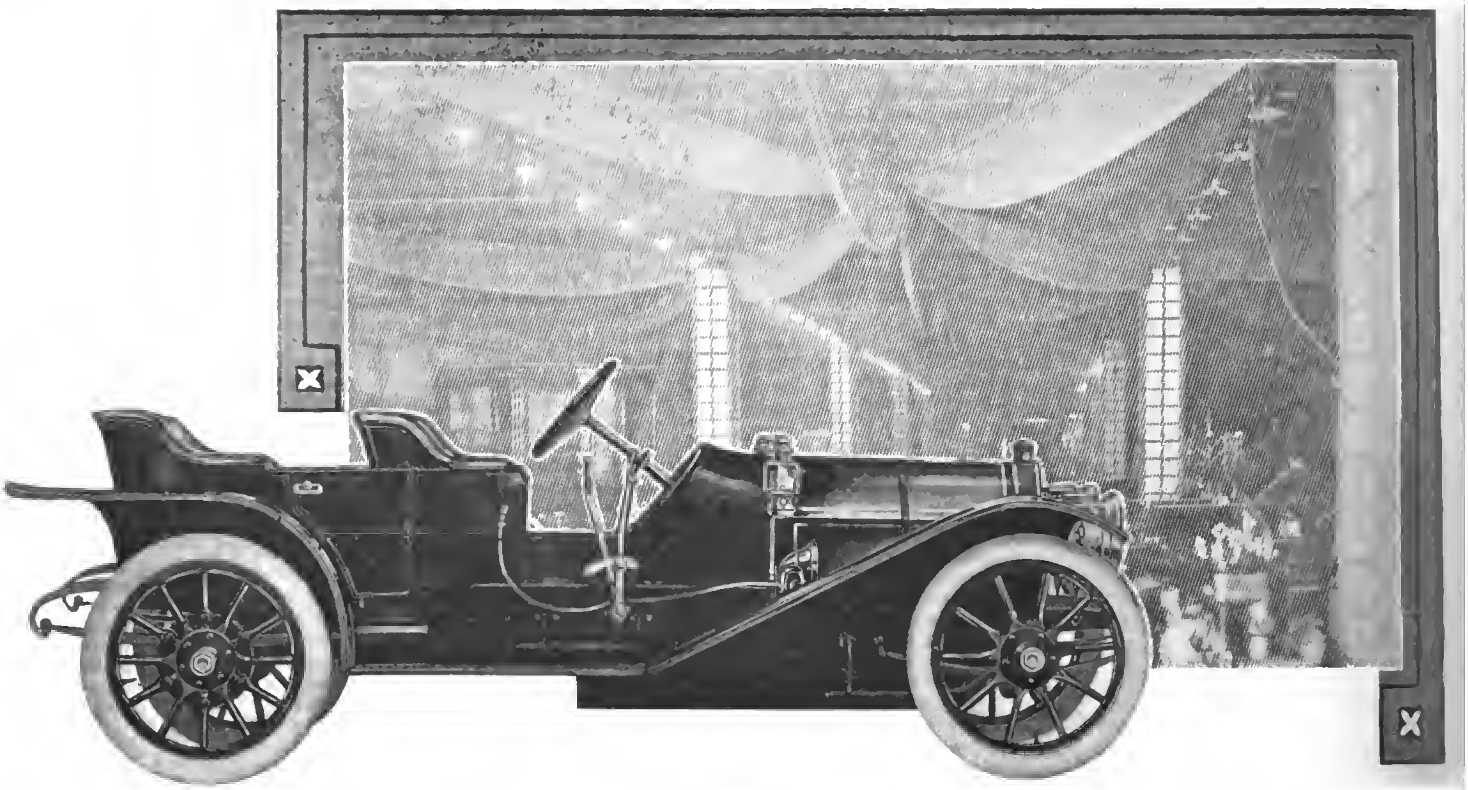
Standing and backing of a firm have a great deal to do with the ultimate best results to be obtained from a car, and considering this, the Corbin Motor Vehicle Corporation, New Britain, Ct., considers itself eligible for a large share of the possible business to be done in 1910. This concern is associated with other large manufacturing establishments, the cars have been the results of splendid engineering skill and knowledge, and it is the announced intention of the factory that the same standards shall be maintained throughout the immediate as well as future seasons.

As in the past the efforts of the entire force will be concentrated upon a single model, giving the experiences gained in five years of making Corbins, and some of the constructive details proven in the models in which they were pioneers are important still. With one type of chassis will come two motors, either water or air-cooled, though the latter will be made only on special order, and the two engines are interchangeable, of course, with their individual fittings. The success of the 1909 season was so marked that the prospects become bright for an even more flourishing one ahead and orders for material sufficient for 600 automobiles have either been let or are pending. It is planned by the officials to turn out that number of cars during the 1910 period and already deliveries have been going on for a month.

WHAT HAS BEEN DONE IN REFINEMENT

As has become somewhat general among the stable members of the industry, standardization has been attained to such a degree that few deviations are necessary. In the new Corbins this will be well illustrated, for the variations from previous practice may be counted upon the fingers of one hand. In the motor itself the principal ones include enclosed timing gears, a new type of oil pump and a changed location, and the moving of the magneto from the front inlet side to the rear exhaust side. The oil pump was formerly mounted midway on the exhaust side and driven directly from the camshaft, but now it is further back on the same side and is driven by the same helical gear which operates the distributor. The pump is now a centrifugal one instead of plain-gear and forces oil from the reservoir, under the foot-boards, through dash sight feeds to the four cylinders and thence to the crankcase for splash. The two-to-one or timing gears remain at the forward end of the case and are enclosed in an aluminum oil-tight case. A Bosch magneto is now regular equipment and this is placed at the rear of the exhaust side and driven by aluminum to fiber gears from the camshaft. In previous models this has been extra equipment and provision was made to drive it from the timing gears at the front next to the carbureter. The change keeps all moving parts on one side.

In the chassis the frame has been lengthened $2\frac{1}{2}$ inches and this put into the wheelbase to insure greater comfort.



Of the New Roadsters and Baby Tonneaus, None Has More Dashing Lines than the Chalmers "Forty" in This Model

Houpt Makes Large-Sized Engine

Bristol, Conn., is the home of the Houpt car, a comparative newcomer in the automobile line, but made by a man old in years of experience, Harry Houpt, formerly Metropolitan agent for the Thomas cars. The first car was a four-cylinder sixty horsepower model, but a later model is to be produced of six cylinders, which will be rated at 90 horsepower. The four-cylinder Houpt car is thought to be the largest four-cylinder stock car made in this country; its cylinders are 5½ inches bore by 6 inches stroke, rated at 60 horsepower. The cylinders are cast in pairs, and the valves, 2⅝ inches in diameter, are placed on opposite sides. In general the motor follows standard design. In the tests at Bristol, the motor showed exceptional power and quick acceleration, combined with practically noiseless operation. The carbureter is float-feed, the gasoline being under pressure in a tank slung from the rear of the frame. The water-cooling system employs a centrifugal pump with both

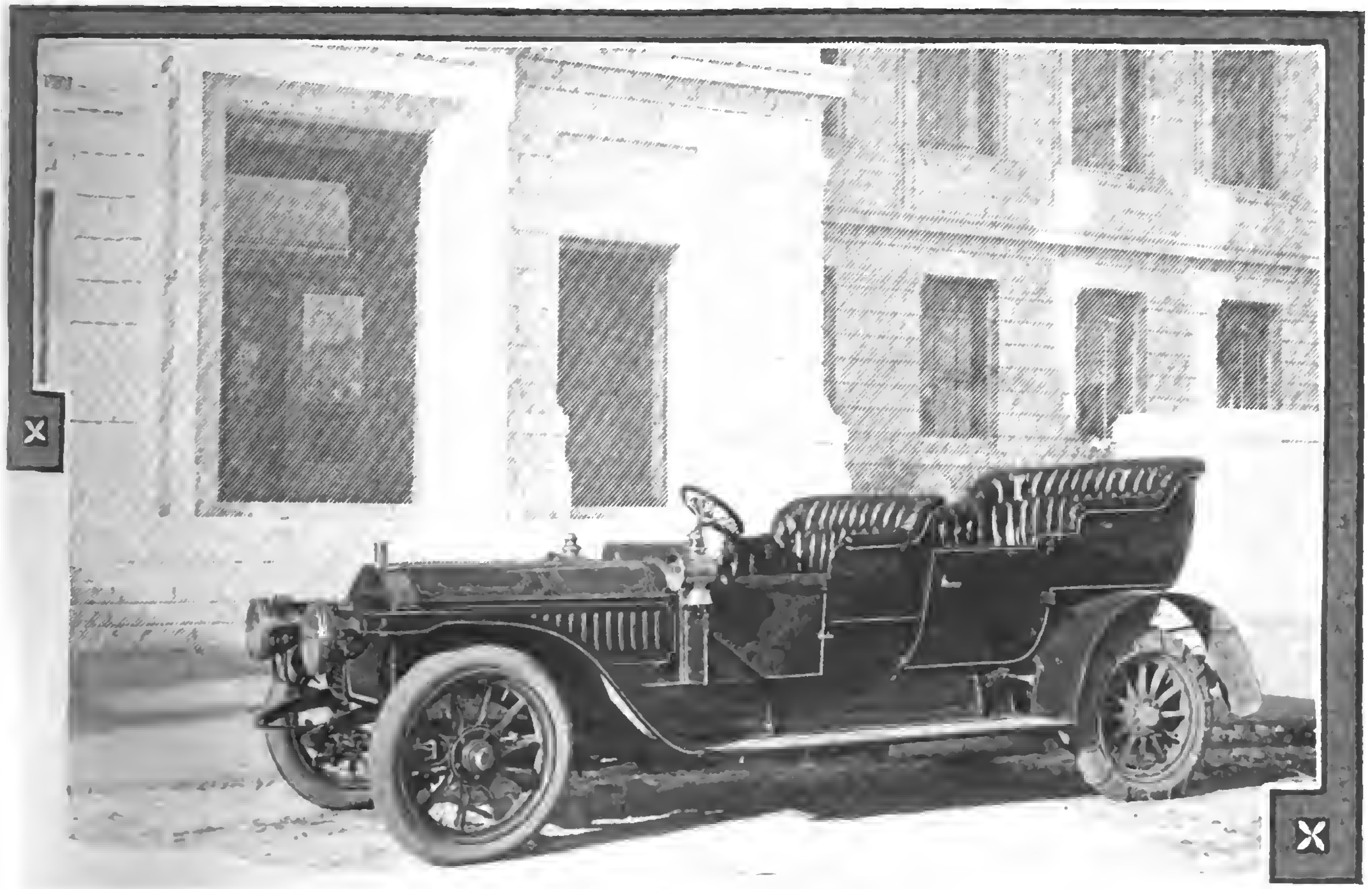
Packard's Body-Building Plant Is Famous for the Excellence of Its Product, Exemplified In This Limousine-Landaulet radiator and flywheel fans. The ignition is double, with a single set of spark plugs in the cylinder heads.

Power is transmitted through a multiple-disc clutch containing 53 steel-on-steel discs, and the change-gear is of the selective type, giving four speeds and reverse. Drive is by a nickel-steel cardan shaft to a full floating type of live rear axle, with bevel differential. The frame, also of nickel steel, is dropped forward of the rear axle and rests on semi-elliptic springs both front and rear. The motor suspension is four-point and that of the gear case three-point. Brakes are internal expanding on the rear hubs and external contracting behind the gear case. The wheelbase of the four-cylinder car is 127 inches; wheels are 36 inches, with 4-inch tires in front and 5-inch in rear. The car weighs 3,100 pounds. The six-cylinder model has cylinders the same size as those of the four, and its power will be conservatively expressed by the maker's rating of 90 horsepower.

ENGINES WATER-COOLED, FOURS AND SIXES

All Knox motors are now water-cooled, with valves located in the head, a location which has become very popular on the other side, being a noticeable feature of every winning car of this season. Model "R" cylinders are 5-inch bore, 4¾-inch stroke, rated at 38 horsepower, A. L. A. M. standard; Model "M" is 5½-inch bore and 5½-inch stroke, rated at 48 horsepower, A. L. A. M. Both have cylinders cast separately; each consists of two distinctive castings—the cylinder proper and the head. The water jacket of the cylinder is cast integral therewith, the water entrance being at the lowest point, and the outlet near the top on the right-hand side of the casting.

In the upper end of the cylinder casting a deep concentric groove is machined in which fits a copper asbestos gasket. Upon this is seated a corresponding concentric tongue formed on the bottom of the head which is firmly secured to the head by four



Boston Is Headquarters of British Napier Car, Which Is Imported from the London Factory

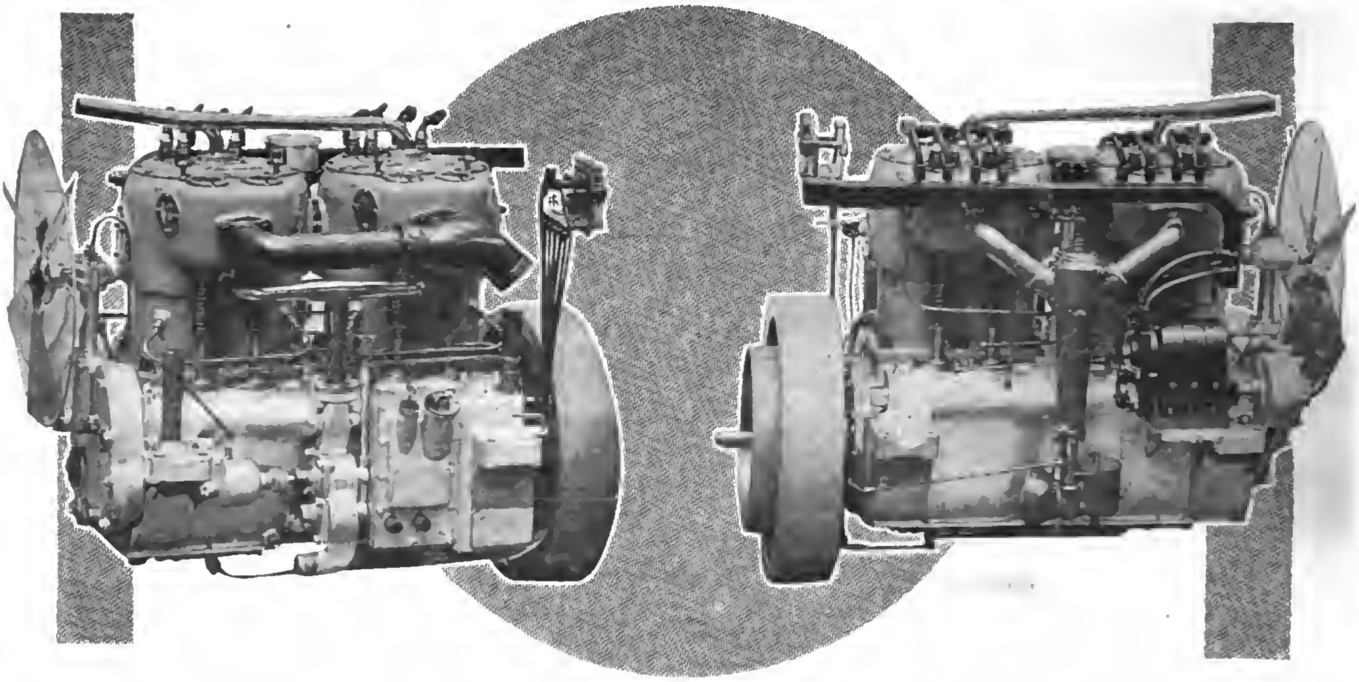
Unit Power Plant a Knox Feature

Among the many excellent cars hailing from the Bay State, no one is more prominent than that hardy pioneer, Knox. This car is made by the Knox Automobile Company, Springfield, [illegible] and contains many features of mechanical excellence, [illegible] been used so long as to be synonomous with the [illegible], might be mentioned: Unit power plant, three-[illegible], multiple disc clutch, double ignition, De Dion [illegible] lubrication, and many more. For 1910 this concern [illegible] out three models, Model M, continued from 1909 and [illegible] on account of its continued successful career; [illegible] different cars just added to the list, Model R, of 40 [illegible], which replaces Model O of last season, four cylin[illegible] a new "six," Model S, rated at 57 horsepower. All of the newcomers follow in a general way the construction of Model O, since the success of that model is taken as the best kind of proof that the form of construction is wholly right. The similarity of the different motors is remarkable.

bolts. It is impossible to bring these parts together except in a correct location and with a correct bearing. This joint, it should be noted, is not a water joint; in fact, there are no water joints in this construction which can occasion a leak into the cylinders.

By this simple construction cylinders are secured symmetrical in form and perfectly uniform in cross section, which fact reduces to a minimum the liability of going out of round. Furthermore, they may be easily and accurately machined, the casting being entirely open at both top and bottom. The bottom of the head is also machined so that the entire surface of the combustion space is smooth and accurate in capacity, giving a perfect balance of the volumes of all cylinders, which contributes to sweet and even running. Machining the combustion space has other advantages, usually not taken up because of the cost.

In addition to this, the smooth surface of the combustion space is less likely to retain deposits of carbon than the rough casting, and the entire absence of sharp points, edges and roughness is supposed to be a preventive of premature ignition. The



Peerless Motor Shows Neat Detail in Exhaust Manifold Jointed for Expansion and in Solid Rubber Bus-Bar

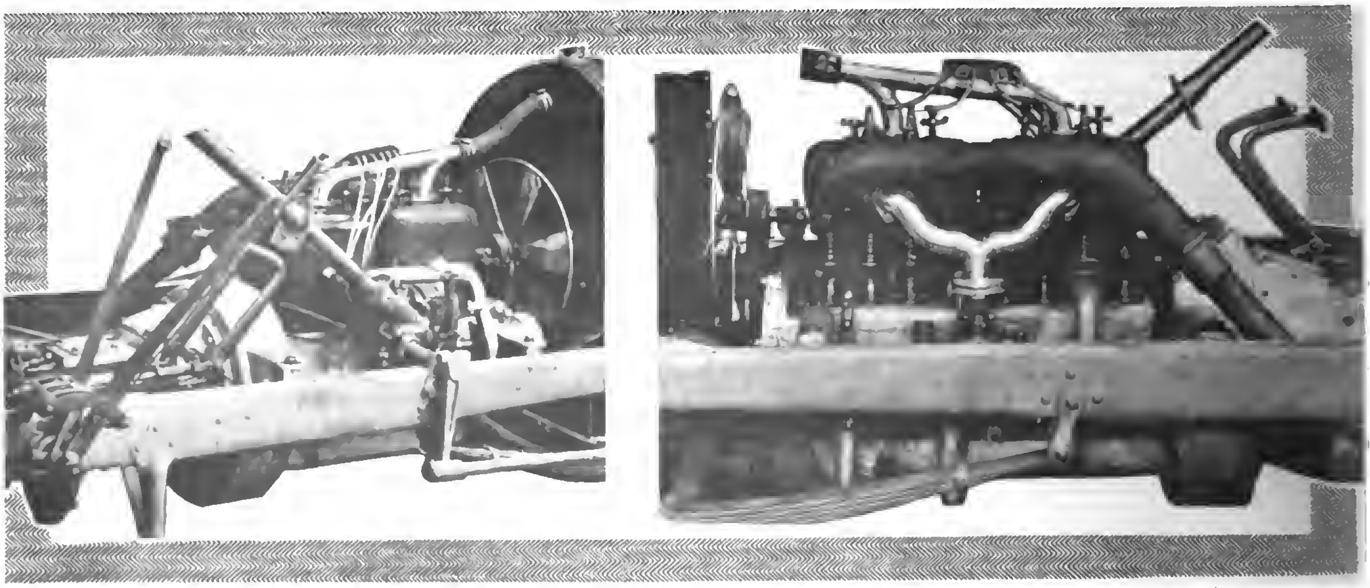
head is cast integral with its own independent water jacket, and the inlet and exhaust passages from the manifolds to the valves are cored in the head. The water spaces are large, the water circulating freely around all the parts mentioned as well as around both valve seats, the head being cast with a division through it horizontally, making two separate water spaces, the water circulation being directly over the valve seats, returning through the top water space to the return manifold, the water entering the lower one through a single U-shaped hollow casting. The "U" connection and the return water manifold are held in place by a double clamp and single bolt easy to connect and disconnect.

Concentration at Hartford

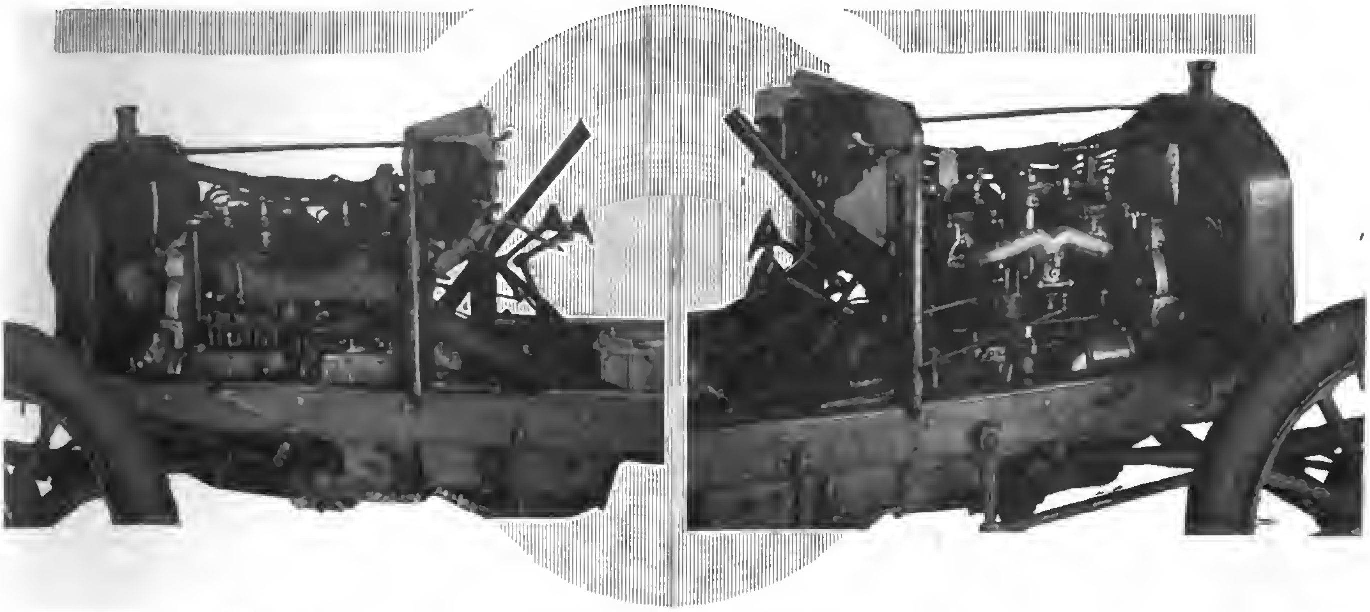
At the factory of the Pope Manufacturing Company, Hartford, Conn., although the body shops are located at Westfield, Mass., it has been decided to concentrate the whole attention upon one model and perfect that. For the year 1910, no attempt will be made at a large production, the modest figure of 1,000 cars being set.

This will bear the name of Model T, is a four-cylinder, 40 horsepower car, and may be had, at the purchaser's option, in six different and up-to-date body types. These are: roadster, seating two, three or four as no rumble, single or double rumble is used; pony tonneau, seating four or five; close-coupled body, seating five; seven-passenger, the name of which indicates its seating capacity; and two enclosed bodies, a limousine and a landaulet.

The changes which have been made since the details of last season's model were announced are few and far between. In the main, they constitute refinements, not changes. Thus, the longer wheelbase allows of a longer, more roomy and, consequently, more comfortable body. The greater length of body calls for slightly different lines, to conform with which the fenders and radiators were altered. The modern tendency to larger wheels is followed, and this year all sizes are 36 inches. The changes which include some actual difference in the design are: the lubricating system; new torque and radius rods; changes in the crankshaft and bearings; new clutch and clutch coupling. All have details which offer many points of interest to the student of automobile design.



Unit Power Plant Is a Cole "30" Feature; Note the Oil Level Gauge and Filling Cap on Valve Side



Mora, the "Mechanically Right" Car, Has Its Fan Driven by a Train of Spur Gears, Completely Enclosed

Doubtless the motor is worthy of the most attention, and this attention will not be wasted, for it possesses many meritorious points. Of the four-cylinder type, with cylinders cast in pairs, heads and water jackets are made integral. The cylinder castings are machined close to size and then ground to an accurate interior surface. Valves are located in the head, in cages which are readily removable and interchangeable. All valves are mechanically operated from the single camshaft on the left side by means of vertical pushrods and overhead levers. The valves are of large diameter, work on a 30-degree taper seat, and are ground to size. The valve springs are enclosed in a neat housing, thus keeping out dust and grit and preventing wear.

MUCH ATTENTION GIVEN TO LUBRICATION

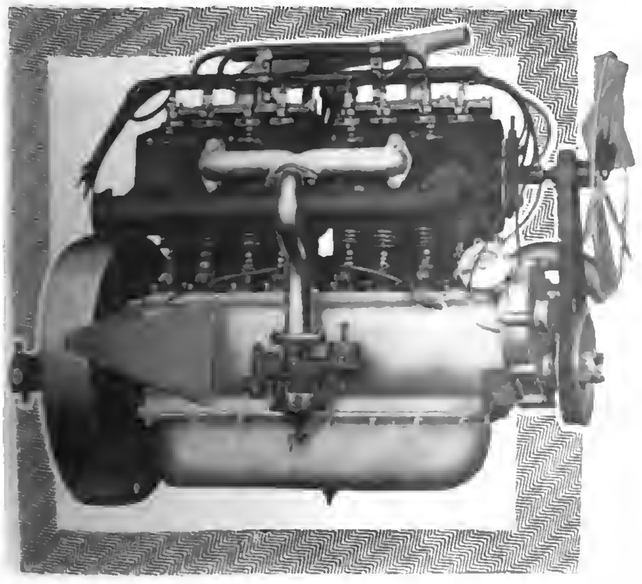
Over previous years, the lubrication is much improved; the mechanical oiler has been increased in size, moved slightly forward, an overflow from the oiler back to the oil pocket placed in the bottom of the crankcase, and a suction pump located in the case, which keeps the oiler body full. The oil pocket is cast on the bottom of the case, and is an integral part of it, although separated by a wall. The complete system is such as to lubricate the whole engine very efficiently. Besides the engine, the oiling of other parts is a subject of consideration.

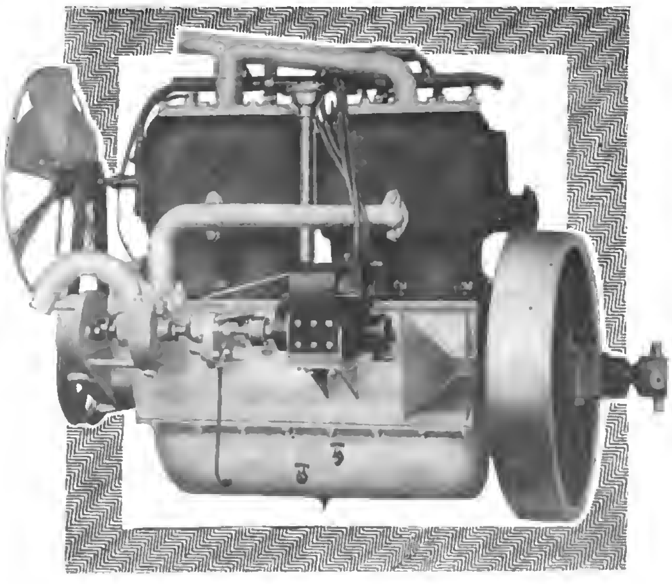
SEVERAL MODELS OF POPE COMMERCIALS

This firm also turns out on a somewhat similar chassis a fine line of commercial cars. Chief among those of this class which have been successful may be mentioned the ambulance, an excellent example of which was recently shipped to as far away a port as Rio de Janeiro. A description of this one will suffice to describe any and all of the ambulances made.

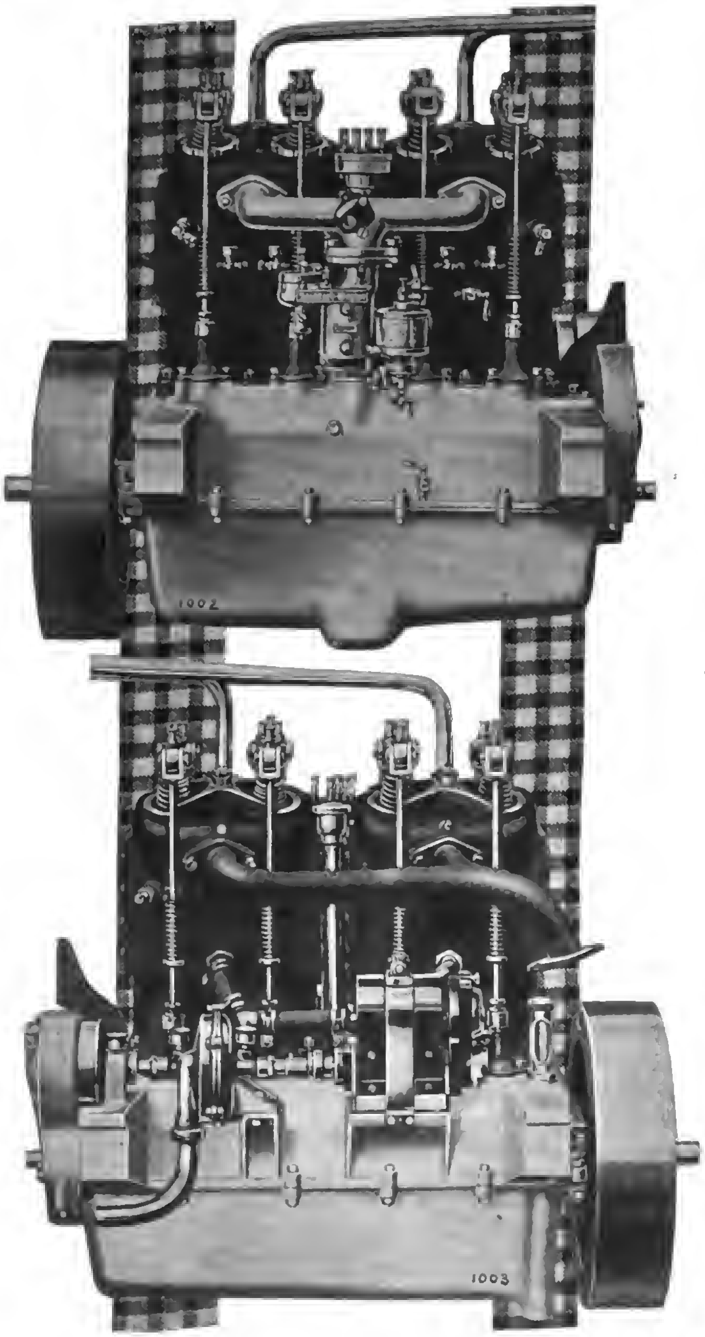
The body was mounted upon the regular chassis for commercial use, this being equipped with a 40 horsepower engine, three speed transmission, 130-inch wheelbase, standard tread, 34-inch wheels, 5-inch tires, and a special sixteen-gallon fuel tank.

Upon this chassis is mounted the body which was built after the special plans by the Navy Department of Brazil. It is very striking in appearance, for instead of the dark colors generally used on ambulances, it is painted with a soft French gray. This makes it more appropriate for use in a warm climate. One of the features particularly distinctive of this ambulance is the top. Here an entirely new idea has been put into effect. Instead of the closed roof, devoid of any means of ventilation, usually employed, this ambulance has what is called the "trolley" top. In this the top is carried up a little way above the sides, giving room for four oblong windows on each side and two both in front and in back.





As a Separate Unit, the Inter-State Motor Is Supported at Three Points; the Clutch Is in the Gear Box



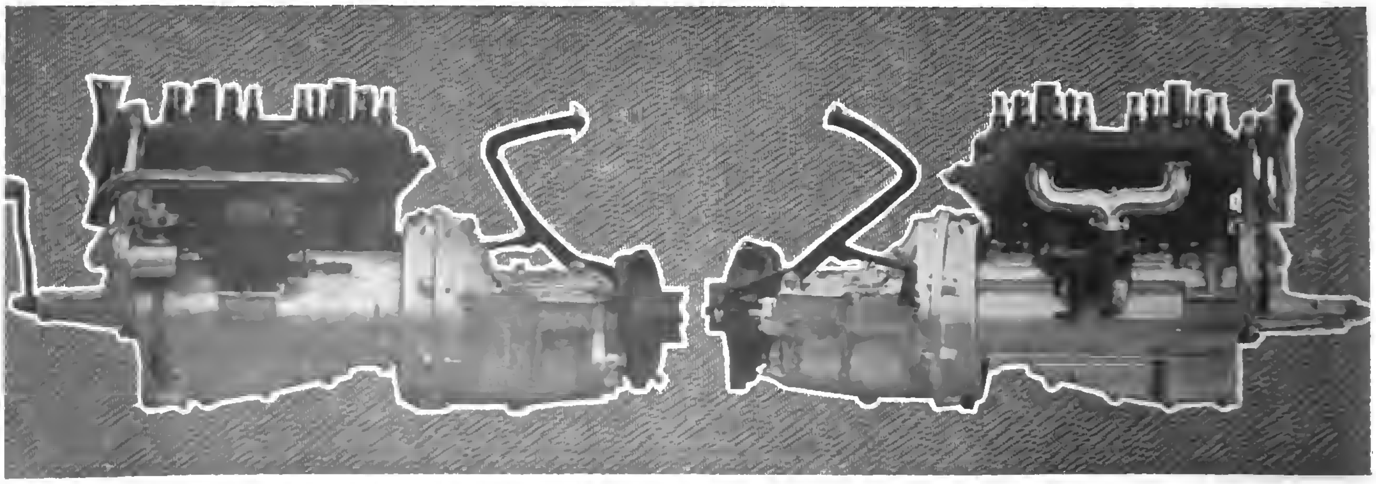
Stoddard-Dayton Motor Follows Lines Already Familiar

Features of the Noiseless Berkshire

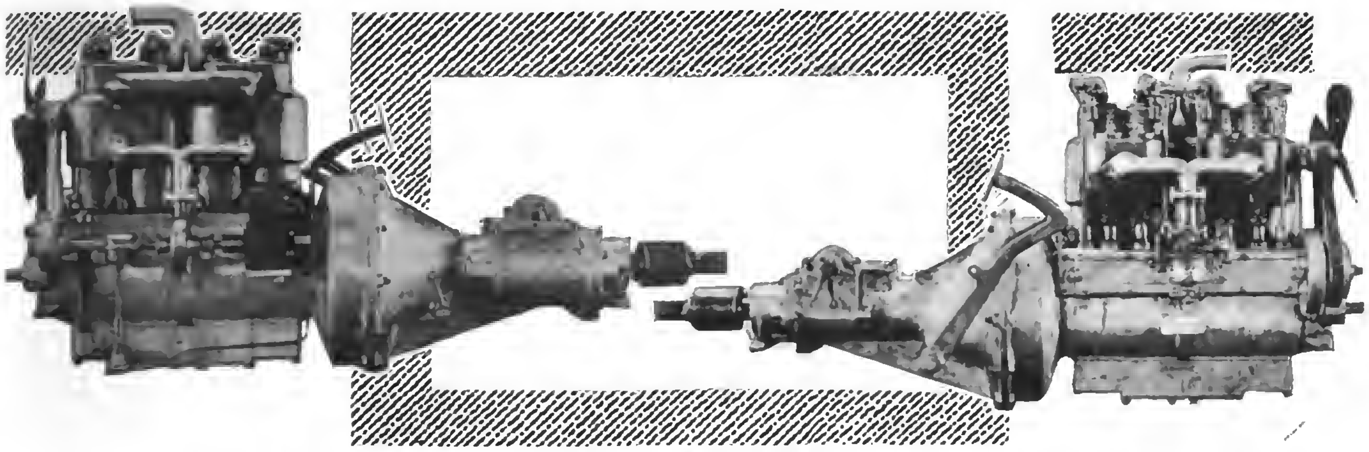
Built in the Berkshire Hills not only gives an idea of the location of the factory of the Berkshire Auto-Car Company, Pittsfield, Mass., but also conveys the idea of strength, rugged and hill climbing ability. The Berkshire motor is a four-cylinder vertical water-cooled type, and is rated at 35-40 horsepower, the rating by the A. L. A. M. formula being the former figure. The cylinders are cast singly with water jackets integral of a special gray iron which combines endurance and strength, and which by virtue of its composition resists wear better than the ordinary grades employed for this purpose. The water jacket spaces are of ample proportions and all parts are well surrounded by water. The cylinders are of the T-form, the inlet valves being at the right side of the motor, the exhaust members at the other. Special stress is laid upon the method of finishing the cylinders, foreign practice being followed. The cylinder after rough boring, and when the valve seats have been finished, is allowed to age for several weeks, and following the final boring, in which an exceedingly fine cut is taken, the interior of the cylinder is finished to exact size by a lead lap and paste made of oil and fine abrasive. The bore is four and eleven-sixteenths inches, the stroke of the piston five and a half inches. The valves are the flat seat type, a form which gives about 25 per cent. more area than the bevel seat of equal lift and diameter, and which has been demonstrated to be more enduring and to make for quieter operation. These members are nickel steel, are two and one-quarter inches in diameter and are interchangeable. The valve guides are not cast integral with the cylinder, but are screwed into place, making it possible to replace them at slight expense when worn, and insuring the same perfect mixture given when the engine was first built, by eliminating air leaks at this point which are unavoidable after the engine has been in service for a period.

LONG PISTONS WITH FOUR RINGS

The pistons are long, and are of special hard gray iron, and are fitted with four concentric rings all above the wristpin. Five oil grooves below the wristpin make for proper distribution of lubricant to all points on the cylinder wall. The dome head piston design is followed, it being maintained that this prevents carbon deposits by allowing the oil to drain away from the top towards the walls instead of accumulating at one point, as is the case with the flat top piston. Pistons are rough turned, aged and lapped to size in much the same manner as are the cylinders. The wristpin is one and one-sixteenth inches in diameter, of special alloy steel, hardened and ground to size. The connecting rods are of the marine type, and are H-section drop forgings of nickel steel, having a special bearing construction at the big end. The wristpin bearing is a phosphor bronze bushing, while the lower end has separate phosphor bronze caps, bushed with Parsons' white brass.



High Efficiency Characterizes the Herreshoff Power Plant, a Unit Construction with Many Good Details



Location of the Exhaust Valves in the Cylinder Heads, as on the New Lion, Allows Exceptionally Large Area

Many Taxicabs from Bristol Works

A limited number of Rockwell public service cabs, manufactured by the New Departure Manufacturing Company, of Bristol, Connecticut, are now on the market. This company has been manufacturing this cab for some time past, but its entire output has been taken by one concern. The contract has been completed and cabs are now available for purchase.

The Rockwell taxicab is distinctive in design and construction and offers a combination of advantages that appeal to both the operator and the patron. In the development of this cab, the company's designers went abroad and studied all the best makes of foreign taxicabs. Two hundred of these cabs have been in use in New York City for more than a year. A record of this practical service has proven the extremely low up-keep cost, strength and durability of construction, and economy of operation. During the severe storms of the past winter in the metropolis when the traffic was exceedingly heavy, the cabs were in constant service, and proved their reliability.

The motor is four-cylinder cast en bloc, with a bore of 3⅝ inch, stroke of 4⅛ inch, Bosch high tension magneto ignition with fixed spark. The force pump spray system of oiling is used with gauge on the dash. The clutch is three plate, floating ring of special design and mounted entirely on ball bearings. The radiator is one of the strongest types and is protected on the front by a heavy grid. The frame is pressed steel, extra wide with exceedingly strong front axle, spindle and wheels. The front and rear axles and transmission are mounted on New Departure double row ball bearings.

An important advantage is the easy accessibility of all parts and the quickness with which repairs or interchanges can be made. The engine and clutch can be removed by loosening four bolts and pipe connections and another set installed in less than half an hour. The coupling to the transmission is made by an Oldham slip coupling requiring no bolts. The control levers are integral with the gear case. The gear case and levers can be removed by lifting the foot board and loosening four bolts. Another set can be installed and all adjustments made in less than one-half hour. All upholstering can be easily removed for cleaning or repairing and is interchangeable.

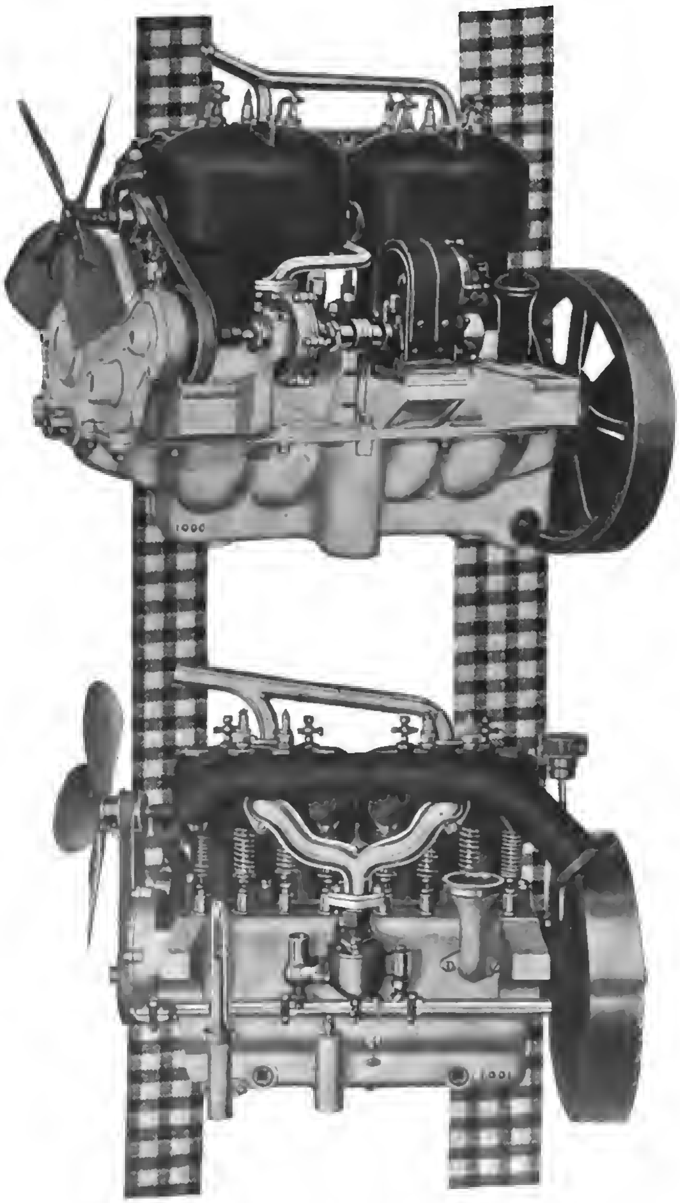
Constructional Differences in Rae

Electrics are also well represented in the list of New England makers. Vermont has few, but that is the part from which the new Rae electric hails. In its victoria electric, many important differences in construction are to be noted.

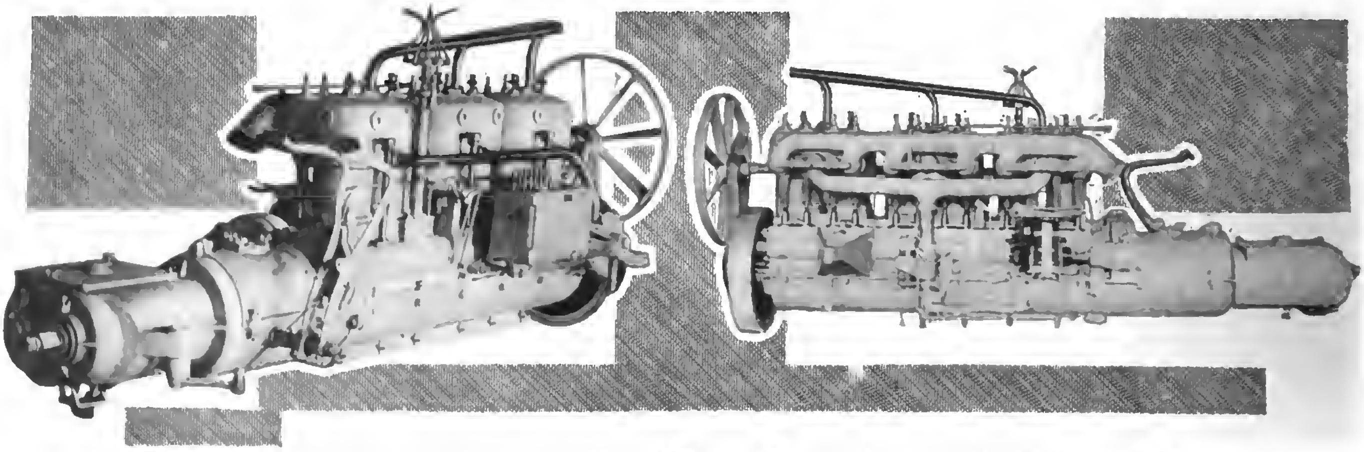
Besides the victoria, the company will have ready for the 1910 season equally well-designed coupé and runabout types of the Rae electric car. The factory is located at Springfield, Vt., but offices have been opened at 747 Boylston street, Boston.

The first machine, as shown at the electric show in Boston last month, had at that time run over 16,000 miles. In operation, it is claimed that this car will cover from 100 to 130 miles per battery charge, and irrespective of the number of stops.

By means of the control of this car, just brought out and patented, the starting and accelerating effort is produced by a normal discharge current, thus conserving the energy stored in the batteries and making a larger percentage of it available.



Two Lambert Motors: Above, Model L; Below, Model H



A Leader in the Adoption of the Unit Construction, Stevens-Duryea Simplifies It by Placing the Flywheel in Front

Sixteen speeds, varying from 3 to 20 miles per hour, are furnished by the controller in its various positions, the operation being such as to vary the field of the motor without external resistances. Noiselessness is made a great feature, being secured by the use of special gears, on short shafts, the latter being mounted upon radial ball bearings. They are well enclosed and run in oil at all times. This enclosing the gears in an oil bath, not only makes for noiselessness, but materially aids the longevity of the gears themselves, to say nothing of the matter of reducing friction losses to an absolute minimum quantity.

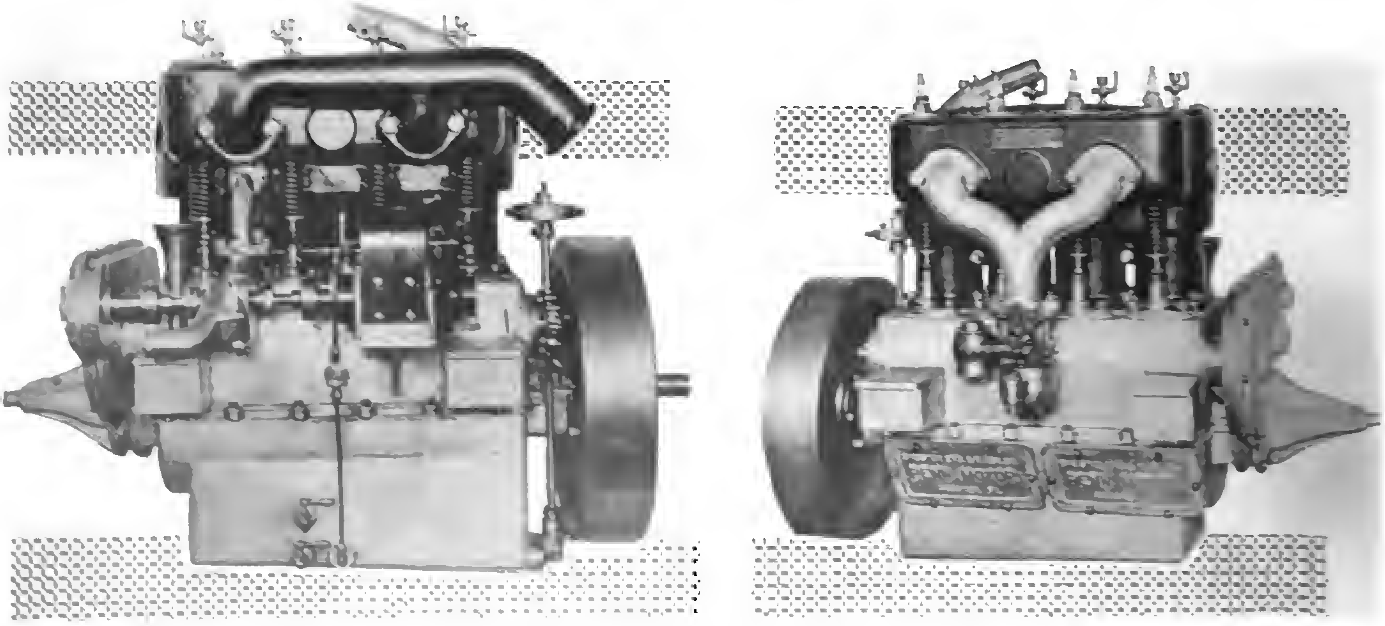
Stevens-Duryea Sixes and Fours

Six-cylinder engines have had at least one steadfast adherent in the Stevens-Duryea Company, Chicopee Falls, Mass., and the season's output will contain a good representation of that type of motive power. In addition to this, the New England concern has advocated the unit power plant with three-point suspension ever since 1904, and the cars for the season of 1910 will all contain a power plant constructed along these lines. Such was the clarity of the original ideas in both that no changes have been made from that time to this, and as the present product shows, the construction has not been altered from the first.

This season's leader will be the old standby, Big Six, a six-cylinder forty-horsepower car called Model Y, with cylinders of 4¾-inch bore and 4½-inch stroke. As a standard equipment this will have a roomy seven-passenger touring body. Then there will be two "fours," differing mainly in the bodies and the little changes that go with the different bodies.

MOTOR SIZES AND POWERS

Model Y is powered with a six-cylinder engine of 4¾-inch bore by 4½-inch stroke, rated at forty horsepower. The cylinders are cast in pairs, with integral water jackets and valves located all on the left side. The construction is so planned that nearly every part ordinarily removed may be taken off without disturbing the others. Thus, the exhaust pipe rises above the exhaust ports and passes across the upper part of the cylinder, while the inlet pipe drops down below the line of the openings, in this way making each pipe removable without disturbing the other. The carbureter is made integral with the lower part of the intake pipe, and can be removed with it. Similarly with the magneto, which is located at the rear on the left side opposite cylinder number six. This is driven from the two-to-one gears at that end of the engine through the medium of a small universal joint, which relieves all strain upon the armature shaft and allows its easy removal.

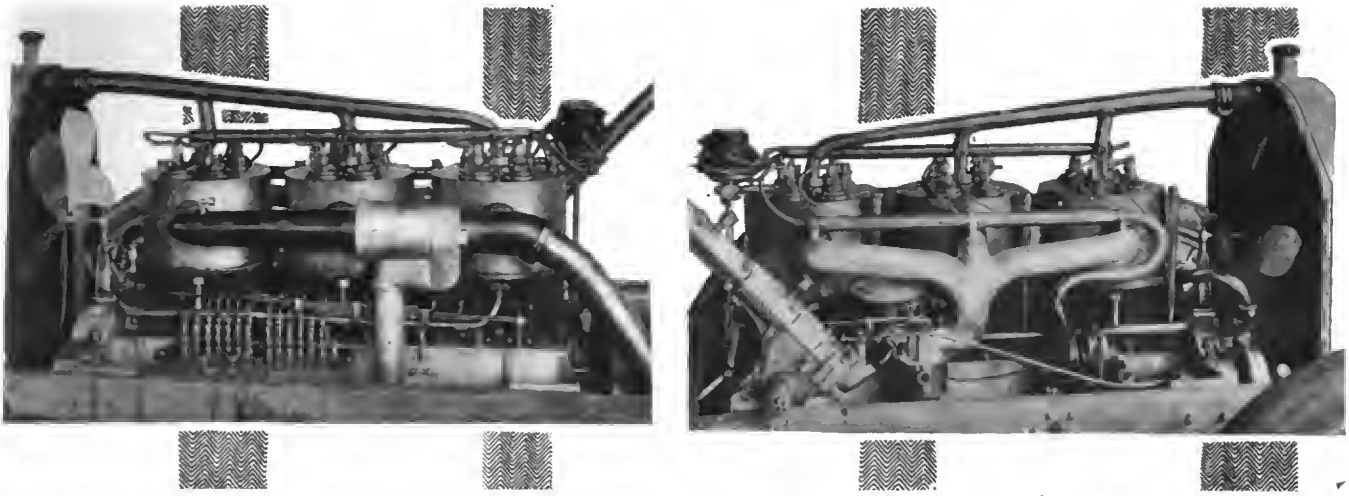


Penn Motor Is One of the New Block Types, with Valves Oppositely Disposed, Which Has a Three-Bearing Crankshaft

Alden-Sampson Commercial Cars

Interchangeability is the goal toward which the Alden-Sampson Manufacturing Company is struggling, the statement being made relative to the product that every part of the "Sampson" truck is designed and built at the factory of the company, and built to jigs and fixtures which guarantee every piece.

During the comparatively short time since the Alden-Sampson Manufacturing Company, of Pittsfield, Mass., developed and



Chadwick "Six" Motor Has Applied Water Jackets of Cylindrical Shape and Retains the Multi-Feed Sight Oiler

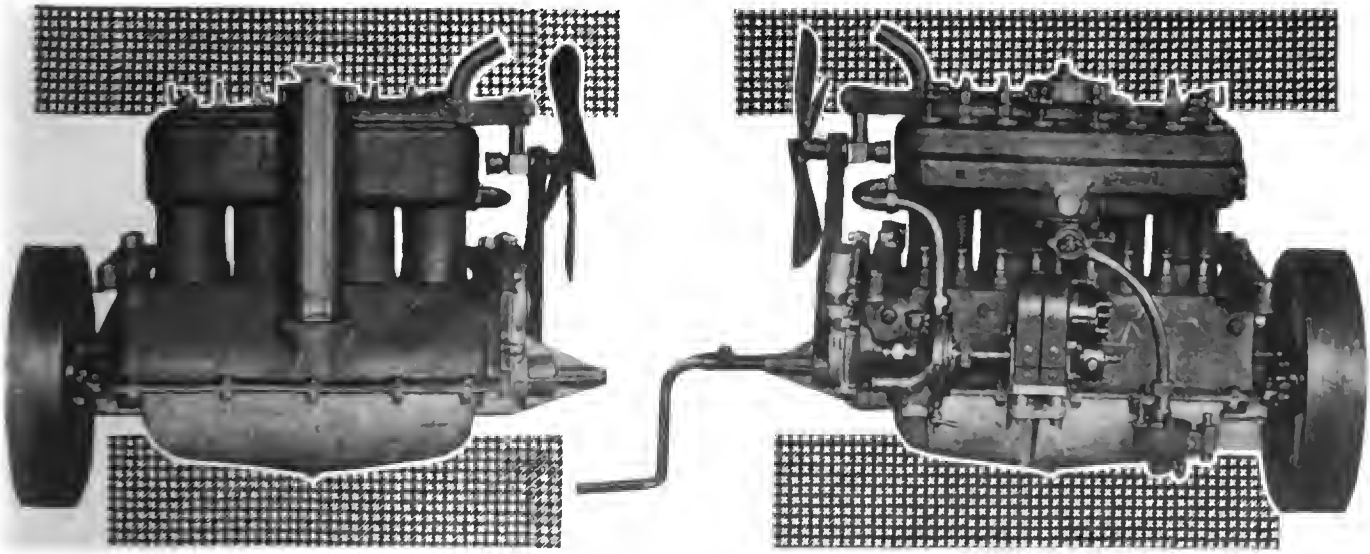
placed one of its four-ton trucks under test in their Motor Transportation Company in Boston, the trucks have excited a tremendous interest among our industries, whose engineers saw at once that here was a truck which embodied ideas and points in design neglected in others, and which seemed to have been designed with the idea that a truck, though doing rough, heavy work, was yet necessarily a machine of fine parts and fine materials, which ought to be protected in their workings to insure economy.

Considering the short time since its development the sales have been most gratifying and the interest shown through inquiries is constantly increasing.

The few points of design and workmanship outlined will show that the effort to build the best and to greatest advantage of the user is always of universal interest. The engine is of 5-inch bore by 5½ inch stroke, and is governed to run at about 925 r.p.m. It is designed and built by the Alden-Sampson Manufacturing Co. especially for truck severity.

in the torque rod support of the shaft-driven cars, the adoption of external and internal brakes instead of the double internal brakes previously used, and a refinement of the brake-adjustment mechanism. Aside from the features above mentioned the general characteristics of the Locomobile cars are similar in every respect. In the Model L 30-horsepower motor the valves are located on opposite sides, camshafts are one-piece drop forgings with integral cams, and the intake shaft carries the igniter cams of the make-and-break mechanism, which have a taper face so that by sliding the entire camshaft endwise the spark may be advanced or retarded. The crankcase is of cast bronze, with its lower removable portion of aluminum. The train of gears operating the valves, pump and ignition is inclosed and runs in oil.

A water-jacketed carbureter of Locomobile design is fitted, ignition is make-and-break, and the cooling system is comprised of a centrifugal pump, a honeycomb radiator and an adjustable belt-driven fan.



Block Construction is Carried Further than Usual in the New Everitt, the Crankcase Upper Half Being Included

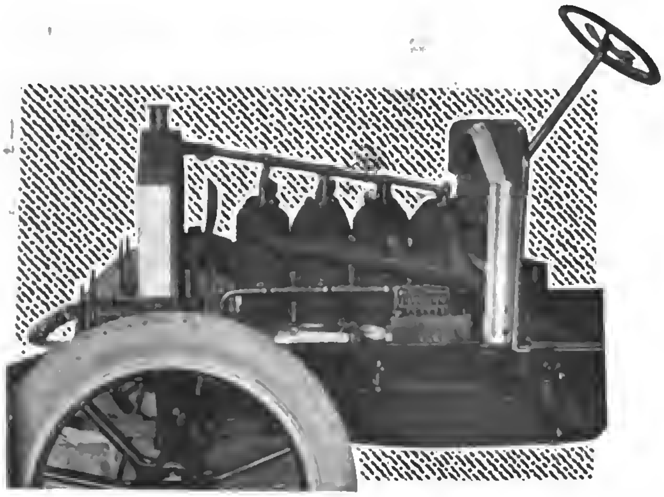
Spiral Timing Gears for Locomobile

The Locomobile line for 1910 remains practically unchanged with the exception of a few improvements in regard to several mechanical details and the general refinement of the product. In the motor the timing gears are now of the spiral type instead of the straight spur gears previously employed; and with the exception of a change in the type of mechanical oiler used there are no further changes. All other mechanical features of the car also remain the same except for an improvement

Unit Power Plant in Sultan Taxicab

In the taxicabs built by the Sultan Motor Company, at Springfield, Mass., the unit power plant idea is utilized, this serving to make the whole power unit removable in a very short time.

The four cylinders of this engine, 3-in. bore by 4¾-in. stroke, are cast in pairs with all valves located on the same side in single combustion chamber pockets and operated by a single camshaft fully enclosed within the crankcase, where it is times exposed to the fullest possible lubrication. The



Great Western Motor Has Separately Cast Cylinders

castings are imported from France, it being claimed that closer and more uniform casting can be obtained in this way. Grinding is extensively employed in the manufacture of these engines, all such parts as cylinder bores, pistons, wrist pins, crank and camshafts, etc., being finished in this way. A high grade of aluminum alloy is used for the crankcase upper and lower parts. All moving parts about the engine are either directly or indirectly carried by the upper part of this case, which is provided with four integrally cast arms by means of which it is attached to the subframe. The crankshaft has three long main bearings of good diameter and it. as well as the pistons and flywheel, is accurately balanced.

New Grout in a Single Model

The reorganized Grout Automobile Company, Orange, Mass., will make but one model. This is offered as a five-passenger touring car and as a toy tonneau, the motor carrying four cylinders which are individually cast and which are 4¾ by 5 inches, giving a rating of 45 horsepower. The valves are interchangeable, mechanically operated, and both sets are on the same side. The lubrication system employs a circulating pump which is located in the bottom of the crankcase, there also being a gauge in the reservoir. The clutch is a leather-faced cone and tbe cooling is by means of a honeycomb radiator and a gear pump, the latter being driven direct from the camshaft. The motor bearings are of hammered babbitt and bronze, while in the transmission, which is of the selective type, Hess-Bright ball bearings are used. The axles are an I-beam in front and floating in the rear and use Timken roller bearings. There are two universal joints on the propeller shaft and a straight line drive is had through strut rods.

Two-Cycle Atlas in Three Models

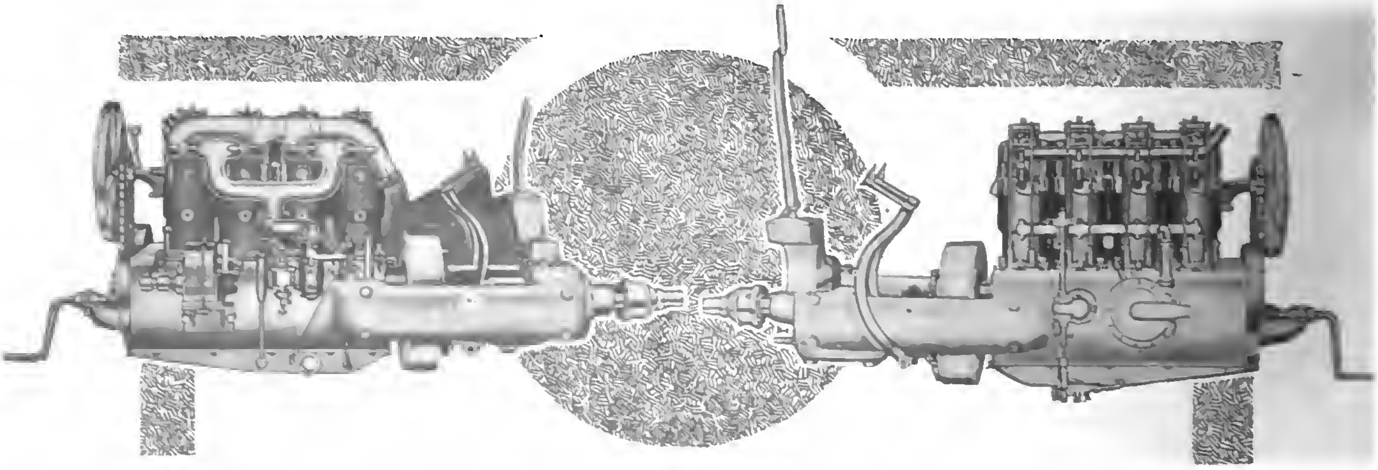
To the discriminating buyer, the makers of the Atlas two-cycle cars offer for 1910, three differing models, each with a two-cycle engine of suitable size and power. Model F, selling at $2,000, has a three-cylinder engine of 4½ in. bore by 4½ in. stroke, and is equipped with a five-passenger touring body. Model G has a four-passenger body, four cylinder engine with 5-in. bore and 5-in. stroke, and sells at $2,500. H has the same engine but a differing chassis, which with a five-passenger touring body sells at $2,500. In connection with the merit of this car, the selling organization of the factory, located at Springfield, Mass., puts forth the following argument why one should buy this product rather than other cars of a competing price and construction: The average automobilist to-day demands safety, comfort, silence, style, power, fair speed, simplicity, durability and low maintenance charge—and usually a fair price. The Atlas combines all of these features to a greater extent than any other car. First.—Safety. Every part of the engine and car is made of the best quality of material—thoroughly tried and tested under severest conditions. Second.—Comfort. Experience has shown that the three-quarter elliptic spring now being generally adopted and first used in this country on the Atlas cars gives the easiest riding car eliminating all side sway of the platform springs—the springs of the Atlas are extra long, three-quarter elliptic, made from imported Krupp silicomanganese steel, the best material known for this purpose—which, combined with the long 128-in. wheelbase, gives a car which for comfort has no superior. Third.—Silence. The absence of external moving parts makes the engine the quietest engine running. Fourth.—Style. Atlas cars are classy in lines, are bighly finished and handsomely upholstered in hand-buffed leather with every convenience and comfort.

Low-Priced Car from Waltham

In the Metz Plan car, the lower limit of automobile price has been reached, this being sold in parts, so that one may buy and assemble at leisure. This plan also allows of buying at one's financial convenience, and has many more advantages, some of which are well told by the makers, C. H. Metz, president of the Metz Company, Waltham, Mass. He says: "No argument will induce the man who longs for a palace and who has the means to acquire it, to put up with a modest cottage.

"The expense of maintaining our little car in comparison with the big tourist is in about the same proportion as the cost of dwelling in a cottage is to the luxury of living in a mansion.

"If it is a matter of how many miles per dollar for your automobile use and pleasure, we can figure as close as anyone in the business, and our statements can be substantiated. We do not pretend to tell you what you should purchase, but you owe it to yourself to ascertain which car will carry you the farthest with the least trouble and expense."



Massachusetts' Old Guard Includes the Knox, a Believer in the U :it Power Plant, with Other Original Features

Stanley Steamers in Three Models

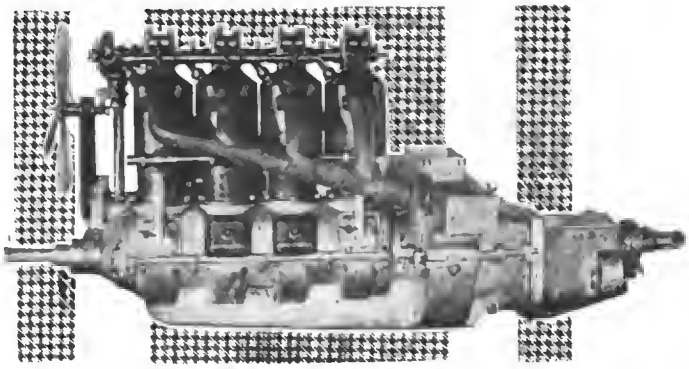
Newton, Mass., is the home of the Stanley Motor Carriage Company, which builds the well-known Stanley steamer. This is turned out in three models, known as "60," R, and U. All of these have two-cylinder double-action, simple steam engines. Model "60" has a cylinder bore of 3¼-in. by 4¼-in. stroke, using slide valves, the engine being located on the rear axle. All of this is true also of Models R and U, except for the engine sizes which are then 4-in. bore and 5-in. stroke. In every case the boiler is of the flash tube type. No condenser is used. There is no transmission, speed variations being effected by changing the speed of the engine. A wood frame is used, and ball bearings throughout, engine and both axles. Model "60" sells at $850 and has a two-passenger runabout body, 104-in. wheelbase, 56-in. tread, weighs 1,500 pounds, and has 34 by 3 in. tires all around. Passing on to the next larger model, R, this sells at $1,400 for a four-passenger roadster, with 114-in. wheelbase, 56-in. tread, and 36 by 3½-in. tires.

New Car, New Plant for McCue

Among the past year's newcomers is the McCue Company, Hartford, Conn., which is building a four-cylinder car to sell at $2,750. This has a number of distinctive features among which might be mentioned the rear axle of special design. In the matter of design, the McCue 40 horsepower motor is most symmetrical, there is not a bad line to the unit and it is built as light as is consistent with hard service demands. The cylinders are twin cast, of the best gray iron, the water jackets are cast integral and are of very liberal dimensions. Even the valves are completely jacketed so that there is no liability to deformation of either valve seat or of valve head under hard continuous service. The cylinders are offset one inch, which together with the long connecting rods permits of slow speed under a heavy load with decrease in wear upon the reciprocating members. It is to be noted that this, the L type, sometimes called the Renault type of construction, is much in vogue in 1910 cars. The cylinder bore is 4½ in. and stroke 5 in.

Newcomer from Bay State--Morse

Among the additional new cars of recent origin is the Morse, made at South Easton, Mass., by the Easton Machine Company. This car is made in two models, of the same price and on the same chassis. The engine is of four cylinders, 4⅝-in. bore and 5-in. stroke. The horsepower rating is 34.3, while the actual piston displacement is 336 cubic inches. Model B is a three-passenger runabout selling at $3,500. Cylinders are cast singly, while the valves are located in the head. The cooling water is circulated by a pump to a honeycomb radiator.



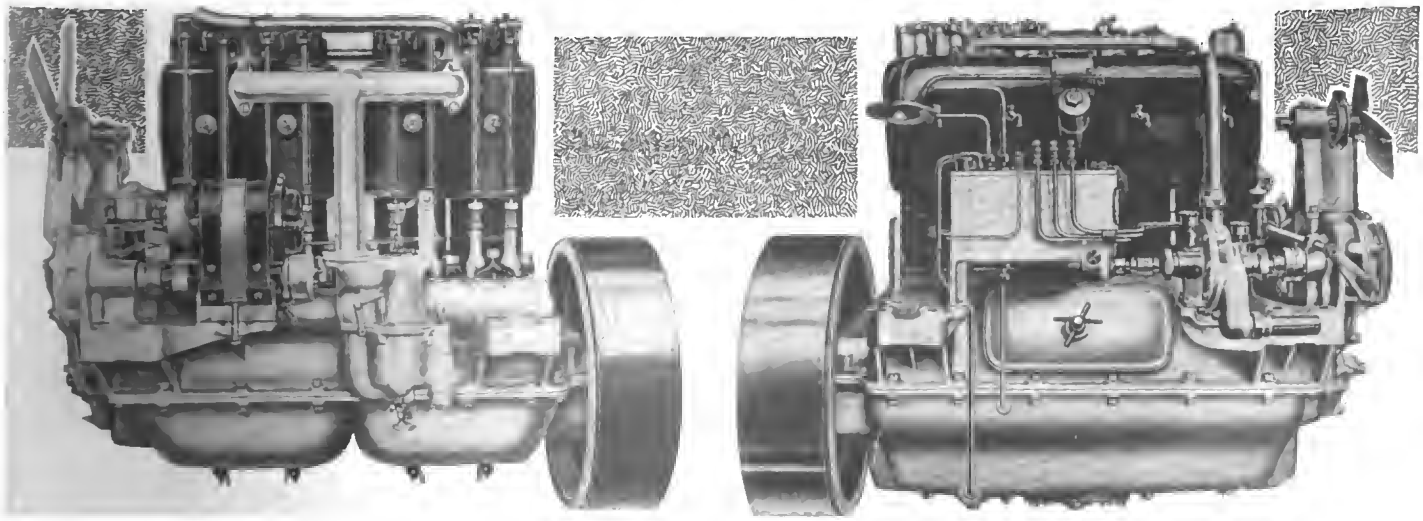
Freedom for Exhaust Is Secured on the Great Western

Morse-Radio—New Englander

Of very nearly the same name, and approximately the same location, the Morse-Radio automobile, made at Springfield, Mass., by the Morse-Radio Auto Company, offers a chance of much business complication. Not that the chassis details agree, for they do not. The four-cylinder motor has a bore of 4¾ in. and a stroke of 5 in., giving it a displacement of 354 in. and a rating of 36.1. The only model turned out is equipped with a 5-passenger baby tonneau body, which sells at $2,500. Paired cylinders of the L type are used, with valves in pockets on the side, of course. Thermo-siphon cooling is through a cellular radiator with a fan as an auxiliary, the latter being driven by belt. A high tension magneto and dry cells furnish the current respectively for the two ignition systems. The contracting band clutch is of steel on a cast iron drum, while the transmission, which is located on the rear axle affords three speeds and a reverse operated selectively. The wheelbase is 112 in., while the tires are 36 by 3½ in. all around.

Among the Foreign Contingent

The British Napier of which a touring car is illustrated, is made in 9 separate models ranging from 10 to 90 horsepower, within which classification no allowance is made for Napier special chassis work. The Napier cars have water-cooled motors with cylinders arranged in pairs, enclosed half time gears, and the company calls attention to the inlet and exhaust valves operated from a single camshaft on one side and many other features which are retained with a view to inducing silence. The ignition is by high tension magneto, gear driven and mechanically applied, with a view to quick replacement. In the transmission system both the fixed and sliding gears are mounted on castellated shafts. The clutches have metal-to-metal faces, are immersed in lubricant, and are not "fierce."



Pope-Hartford Is a Prominent New England Product, and Consistently Upholds the Valves-in-the-Head Idea

In the Selection of an Automobile

BOSTON will be awarded the last comprehensive opportunity of the year to examine the various makes of automobiles, and in many respects the situation will be unique. In former years it has been the practice of makers to go to Boston with their best selections; to present the best foot, as it were and it is confidentially expected that 1910 will be no exception unless it transpires that this condition may be accentuated.

The New England autoist differs from his type in other sections of the country in many respects; he is imbued with mechanical ideas which are bred in the bone; appropriateness appeals to him, and art is far from a stranger to this section of the country. In a sense, Boston is the place where the makers go with their products for approval, and every attempt is therefore made by them to explain the reasons for the innovations of the year, to tell why some of the tried-out features were dispensed with, and to submit the whole to the court of last resort.

The exhibition at Boston will be under conditions which should prove to be more advantageous than otherwise. Most of the automobiles which will be seen there have been examined and discussed, after having been displayed at the shows elsewhere, and the various makers have been most liberal in their attitude as respects visitors to their plants, so that the information given and exacted has proven to be of a much more reliable character than that which appeared in print in former years.

SELECTION IS ATTENDED BY DIFFICULTIES

The situation, despite the wealth of information at hand, is attended by difficulties, due to the large increase in the production this year, and the budding autoist who goes in for his "first" is bound to be more or less disconcerted. It is one thing to examine a given object and determine as to its value in a predetermined service, but it is quite another matter to go to a show, and, among several hundred automobiles, select the one which will represent all that money can buy.

It will not be easy to devise a system which will adequately serve the purpose, but it may be possible to help the situation, and the aim here will be to classify the motors, and introduce a "point system" which, if it is intelligently applied, may help out sufficiently to be worth while. It is believed that the power plant is of such great importance that it will be better to confine the idea to motors only, rather than to try to cover the whole situation, and, as a rule, the automobile which has a properly applied power plant, is so adaptable in other respects, that the purchaser is very likely to find it equal to all of his needs.

Classification of the Cylinders Used in These Motors

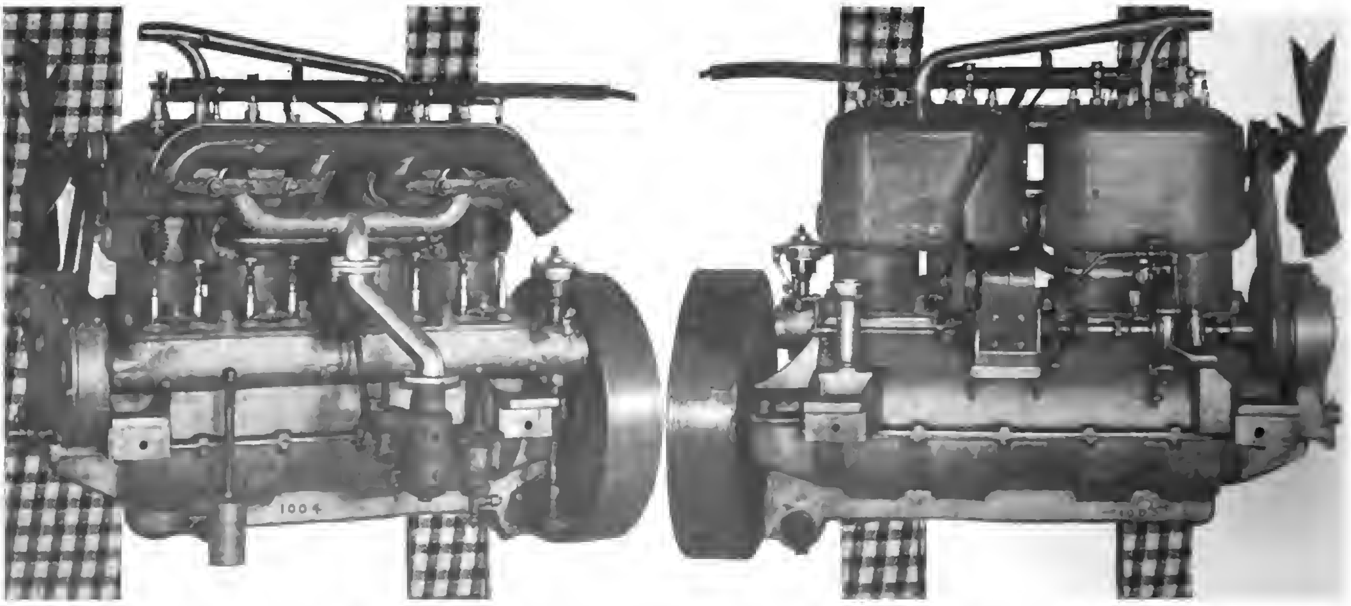
Cast in pairs	215
Cast separately	107
Cast en bloc (4)	26
Cast en bloc (3)	2

What was true at Chicago, comes near to holding for all the products of the year, although, as reported in THE AUTOMOBILE, there were some differences as between averages of the power plants as they were shown at the Palace, Garden, and at Chicago. As for the trend, it is difficult to reach fixed conclusions, but it is possible to say that, at the National Show, the count disclosed a falling off of air-cooled motors from 23 for the previous year to 14 as above recorded, which difference, in all probability, may be traced to the reduction of high-wheeled automobiles, in which type the air-cooled motor is much used.

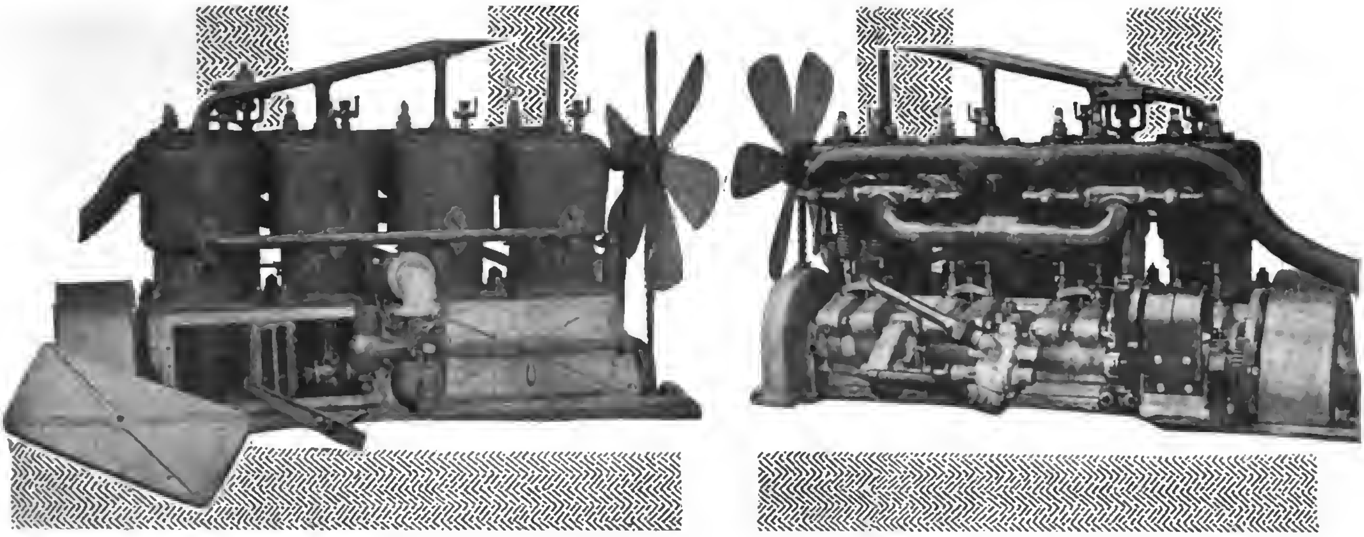
TWO-CYCLE MOTORS ON THE INCREASE

That the two-cycle motor is gaining ground is certain, and a count of the motors of this generic type for two years, shows that where there were ten in 1909, there were fifteen at Chicago.

The two-cycle idea, while it always seemed to be worthy of careful exploiting, had the misfortune to fall into the hands of



Built on Strictly Mechanical Lines, the Selden Motor Appeals to the Engineer More than to the Seeker for Novelty



Corbin, from New Britain, Conn., Believes in Having the Cylinder Stroke Shorter than the Bore

motor boat builders of the class who did low-priced work, and, despite the difference in service demanded in automobiles, these motor designs were retained in some cases, with the result that, while the motors did fairly well, they did not quite come up to the best expectation. The black eye thus administered, although unfair to the good motors which maintained the status of two-cycle work, did exert a retarding influence, and it was not until this year that the atmosphere cleared up sufficiently to enable autoists to judge of the fullest capabilities of this type of motor.

BALL-BEARING CRANKSHAFTS GOOD

It cannot be claimed that this type of crankshaft is being used very much, but the reason does not lie in lack of ability of the type. In every case involving the use of ball bearings, they proved capable, and it is because the plain bearings are also satisfactory that no greater headway has been recorded for the ball-bearing types—plain bearings are less costly.

As to the policy of employing the bearings of the least cost; it comes within the realm of good engineering; an engineer is a man whose skill permits him to get all there is in material, and accomplish the given task at the least possible cost. It is but half of the problem to make a thing work, and in commercial life, it is feared that an engineer without the ability to make material go as far as possible would fail.

PLAIN BEARINGS ARE CAPABLE

Plain bearing crankshafts are used in three ways: (a) With a bearing on each side of each throw; (b) three bearings for a four-throw crankshaft; (c) two bearings only.

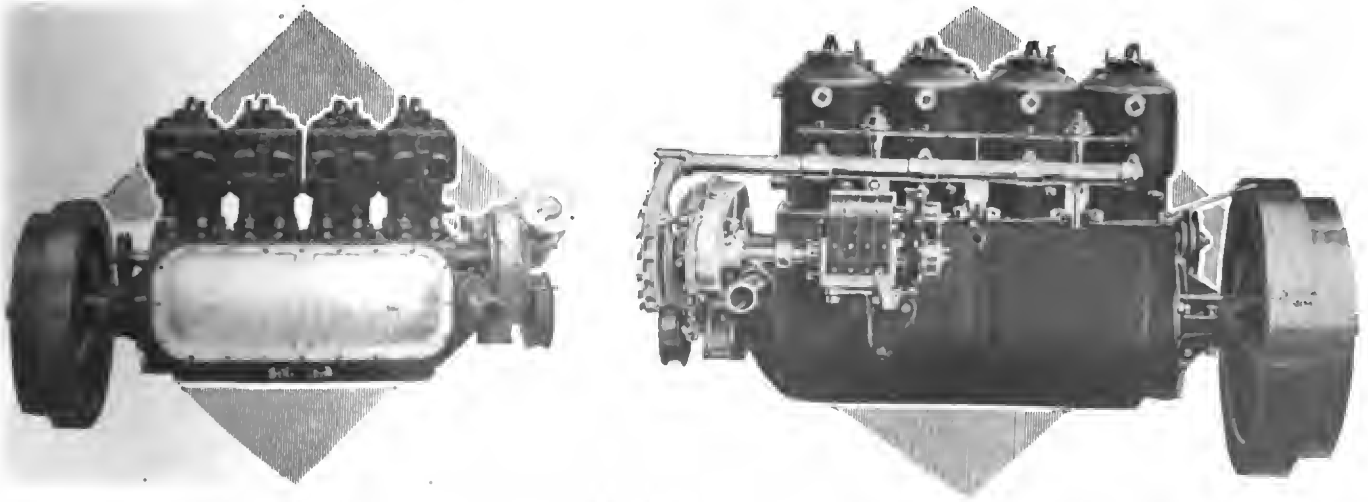
It is useless to argue that one of these types is better than the other without considering the quality of the material, design, and execution. The way to reason out this question is to note the character of the design and the other structural details, and to remember that, as in bridges, which are of divers designs, as cantilevers, suspensions, Howe truss, etc., if the designer takes all the factors into account, the results will be satisfactory.

CAMSHAFTS ARE MUCH IMPROVED

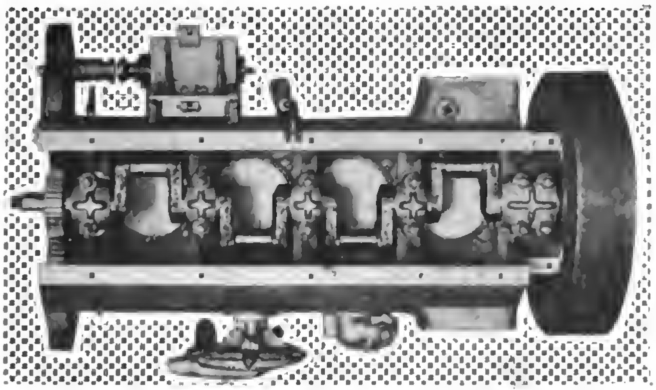
Accuracy of contour of cams, correct angular displacement of them, and matters of this sort, are of far greater importance than it is to have the cam-shapes conform to the constant velocity theory. It would be a nice idea were it possible to so design the cams that the gas would enter and exhaust at a constant velocity, but freak shapes are likely to result in noise and other troubles of a character which is beyond the skill of the autoist to cope with.

By taking advantage of camshaft grinders, which are now to be had, materials of the hardest character may be used. The process of heat treating and straightening may be conducted before the camshafts are finished. The great endurance of the material after hardening is no bar to quick and accurate finishing. It is just possible that the finishing may be hastened, owing to the rigid character of the material which is reason for its ability to stand back of the grinder in the final process, and the tools during machining.

In the setting of valves, overlapping is now practiced as never before, that is to say, the inlet valve is opened before the exhaust valve is closed, and in this way the inertia of the gas is taken



Rambler Secures Accessibility of the Cranks and Cams through an Unusually Large Hand Hole



Good Example of Five-Bearing Crankshaft Construction

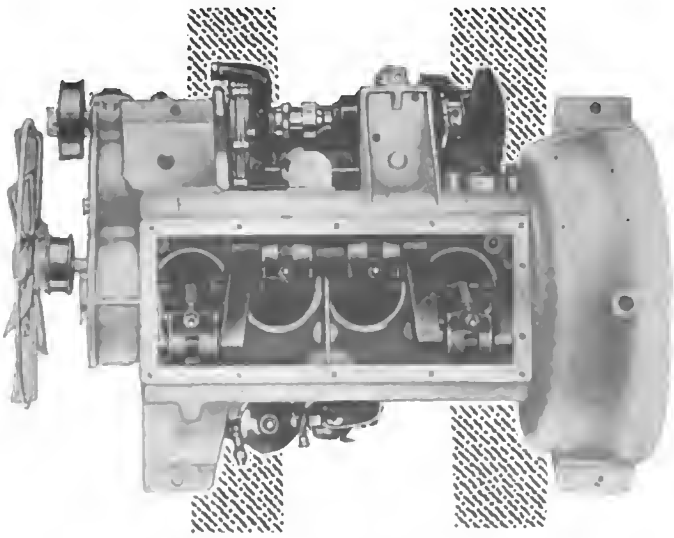
advantage of. This practice demands careful and nice designing, and the very fact that it is practiced is assurance of the growing quality of motors.

The sizes of valves are about on a par with last year; the designers who prefer the large valves make adequate provision to eliminate the noise which is likely to be induced, although, considering high compression, and high speed, which are companions to large valves, the power of the motors for a given bore and stroke, is greater. It is the general practice to so design motors (large valve types) that the valve diameters are equal to half the bore, and bevel seats for valves are prime favorites.

VALVES ARE VARIOUSLY LOCATED

In some of the earlier racing types of motors again in power resulted when the valves were located in the heads. The intense heat in this location made for trouble, but this tendency was counteracted, and it then became commercially possible to take advantage of the noted increase in power. This type of motor is conspicuous this year, and the reports from it are so thoroughly good that it promises to be perpetuated. In some of the designs of this type the valves are in cages, and they may be readily removed when it is found necessary to clean or grind in the valves. In the Knox type, which is a distinct and clever innovation, the head is separable, and when it is desired to clean out the combustion chamber, all that is necessary is to remove the nuts from the holding bolts and lift the heads off; room is then at hand in which to work a scraper.

When the valves are in cages, and with a view to thwarting the ills of excess heat, the cages fetch up on flat seats and have room to expand. The cages are made of cast gray iron of a grade which compares favorably with the iron used in the cylinders and pistons, and packing is done by grinding. The practice,



Chalmers "30" Has Two Bearings of the Annular Type

considering the T and L head cylinders, is not very different from last years; the compression may be a little lower considering a struck average, and the valves may be a little greater in diameter. It is just possible, too, that bushings are more freely employed for the stems to reciprocate in, but it is not admitted by many of the most advanced designers that this practice leads to any special advantage. The valve action seems to be satisfactory in either event, and as for the valves becoming too loose in the guides, there seems to be little chance of it. As an instance of the durability of cast gray iron under the conditions as here reflected, it is enough to point out that motors have been examined after eight years of service and when they were taken down to ascertain the extent of depreciation, the wear of the valve guides was found to be negligible.

Adjustment is more carefully provided than in earlier designs, and it is now the belief that the adjustment should be very nicely made, or the system should be without means. In the absence of a means of adjustment, there is nothing to jar loose. Valve springs are stronger than was formerly considered desirable; this advantage, for such it proves to be, is not attended with a great disadvantage in view of the quality of cams and rollers as now made. It has been determined that the quicker closing of the valves, due to the stronger springs used, adds materially to the power and efficiency of the motors. In some of the earlier types of motors it was nothing to observe a camshaft rotation of even 40 degrees during the seating of the valves. At the present time the camshaft rotation is, in the better examples, on the efficient side of 20 degrees.

RECIPROCATING PARTS ARE LIGHT

When a member is balanced, according to the popular conception, it will stay in any position in which it may be placed, but it is not generally appreciated that this condition of static balance is of no avail. Just so soon as rotation is set up in a member, it then partakes of kinetic properties, and, unless it is in a state of kinetic balance, vibration will set up, and this vibration is but the visible manifestation of a more serious condition—kinetic strains are induced in the member, and they increase as the square of the velocity.

It is this kinetic ill which is at the bottom of most of the crankshaft failures, and in any attempt to determine how good an automobile may be, it is necessary to observe the condition of kinetic balance. Makers, who value their reputation, can scarcely be expected to disregard this highly important matter, and it is this hidden structural consideration which has been attended to by the makers of the best automobiles of the year.

The best condition of the kinetic balance will be observed in the motors which are provided with well-designed reciprocating parts, and especially if each reciprocating part is to an exact standard of weight. Good material then nice design features, and finishing to exact drawing size, is what is aimed at.

TIGHT COMPRESSION DUE TO GRINDING

Cylinder grinding has been in vogue for several years. It was formerly looked upon as a process which was only resorted to in the manufacture of high-priced automobiles. This year, from an actual inspection of fifty-five plants devoted to the manufacture of automobiles, only one was found which was not equipped to grind cylinders. In this case the grinders were actually ordered and it was expected that they would be in hand for the year's work. Grinding is a quicker process, and for this reason alone it is adapted.

Grinding, besides reducing the time of finishing, is the best possible assurance that the bore will be of perfectly uniform diameter, even though there may be hard spots over the surfaces of the cylinders. In casting cylinders the metal will not be of equal hardness all over, and while all possible skill is utilized "chill" conditions will creep in, and white metal will gather at zones over the surfaces.

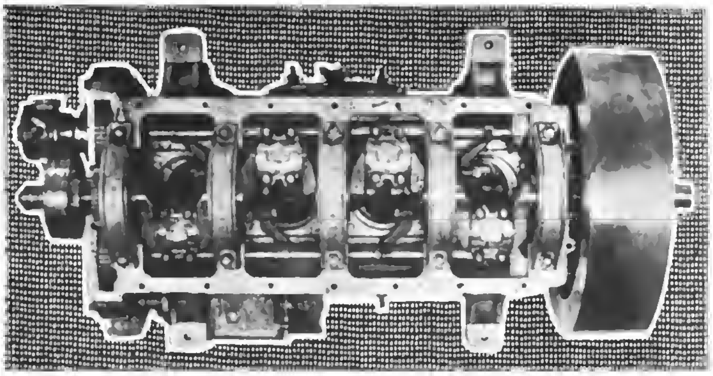
In addition to this condition of chill there is a certain proneness of the metal to remain soft in spots, and in boring the cutter will dig in deeper at soft and back off when hard spots are encountered. Grinding has none of these drawbacks; the surfaces are ground off at the same rate, irrespective of the hardness of the metal, and inequalities, although scarcely noticeable to an observer of little skill, will allow gas to leak by.

Since grinding is the quickest way to finish cylinders, it is the best possible guarantee that this process is followed in the low priced automobiles as well as in the more pretentious efforts. The cylinders are first wrought, bored, and then mounted in a fixture, or bolted to an angle plate on the platen of the grinder, where the final finishing is done. Pistons are also ground, and the allowance for expansion due to heat is very carefully cared for. Expansion allowance has not been reduced to a standard basis, and this, as well as a number of like details, will have to be given a little attention in the long run.

The piston rings, of which most motors are provided with four for each piston, are made of a special mixture of cast gray iron. The rings do not have to be of great section, and so fashioned as to press heavily against the walls of the cylinders. In some of the earlier designs of motors the "pumping losses" reached the enormous figure of 1 1-4 horsepower per piston ring used, and the mechanical losses were excessive.

In the absence of skill borne of experience, this condition is bound to creep in, and "paper experience" when it comes to matters of this sort, is worth very little. It is on account of this, and other similar matters, that motors, if they are given a displacement rating, will scarcely be on a fair basis of comparison. There is no way known to engineers by which the factor "skill" can be introduced into the formula, and in the absence of this, the accurate way to ascertain the true rating is to test it.

This, and many other reasons, are at the bottom of the problem which is bound to confront the man who goes in quest of an automobile nor is it likely that the time will ever come when the search may be conducted without having to allow for the personal equation. The nearer the approach to a standard, the less will be the hazard, and, while it cannot be claimed that automobile motors are even approximately on a standard basis, they are sufficiently perfected, taking them as a whole, to assure purchasers that the difference between the worst example and the best motor is nothing like what it was last year—each successive year brings its quota of refinement in this respect.



Crankshaft with Five Bearings of the Annular Ball Type

POINTS OF MERIT IN SELECTING A MOTOR

Were the whole matter put on a civil service basis, the points of merit might be approximated as follows:

Conditions to be considered.	Points.
For each year of service rendered	5
For a tight compression without an oil seal	10
For each 10 degrees reduction of the temperature of the cooling water below 212 degrees F. (to 170 degrees F.)	10
For each one per cent increase in thermal efficiency	10
For a straight line torque performance up to 1,000 feet per minute of piston travel	20
For accessibility, ease of adjustment, etc.	20
For each reduction of 1,000 pounds per square inch of extreme fiber strain due to secondary moments at 1,000 feet per minute of piston travel, measuring the strain at any point desired on the section of the crankshaft	20
For tight cylinders under a hydrostatic test of 500 pounds per square inch	20
For perfectly round and parallel cylinder bores	10
For noiseless performance	25
For absence of packed joints	10
Per pound per square inch of back pressure removed	20
Per pound of suction depression removed	30
For a securely fastened flywheel	20
For integral or equally secure cams	20
For a satisfactory wipespark system of ignition	20
For a satisfactory system of high tension magneto	20
For a satisfactory dual ignition system of ignition including a magneto	30
For a satisfactory double system of ignition, including magneto and a multi-coil	30
For a satisfactory double system of ignition with a magneto and a uni-sparker	30
For an ignition system in which the wiring is run in a proper conduit system	20
For a carbureter which will deliver gas of uniform density at all speeds of the motor	30
For a motor which can be assembled and taken down without having to use a special wrench or tool	30
For a motor which will not pop back in the carbureter under any condition of mixture	10
For a motor which will start on a quarter turn of the crank in zero weather repeatedly	100
For a motor which will start on the spark repeatedly after it is shut down for a period of 10 hours	100
For general appearance and exterior finish	20
Considering a given gear ratio; for a motor which will accelerate the car it is placed to drive, from a standstill to maximum speed in the shortest time	30
Considering a given gear ratio; for a motor which will drive the car it is placed to drive, up a ten per cent. grade, on "direct" at 1-4 (or better) of the best speed of the same car on a level	100
For a motor which is positively lubricated and capable of running 10 hours without having to be attended to (no addition of lubricating oil)	100
For a motor without any exterior oilholes to be cared for	40
For a motor which will not leak lubricating oil	10
For a motor which will not smoke	10
For an installation which is tight enough to exclude dust (a satisfactory system of pans)	100
For a motor which will deliver the power required on a gasoline consumption of one gallon for each ten miles	10
For each additional mile per gallon	10

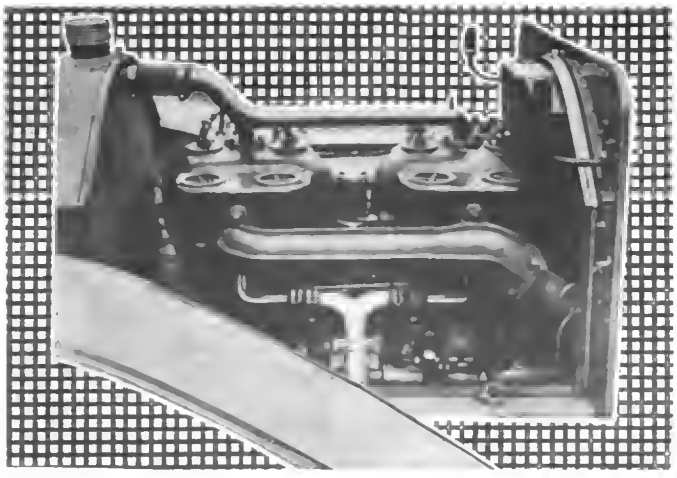
SELECTING A CAR IS A PROBLEM

The above system of rating a motor assumes grave complications; it will take considerable time to so develop it that it will be fairly representative of the true situation, and it is highly improbable that any two engineers would agree that a given number of points will truly represent any given condition. The idea, for illustration, of giving 100 points to positive unattended lubrication for 10 hours, and only 20 points for tight cylinders under a hydrostatic pressure of 500 pounds per square inch, would lead to discussion, and it might be the consensus of opinion that the rating should be reversed.

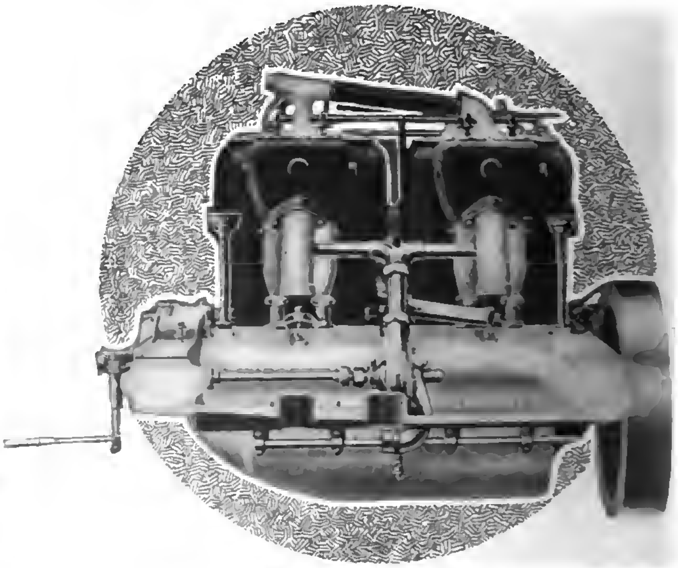
Considering the purchaser, however, he can ascertain for himself, if the lubricating oil will hold out for 10 hours, but he will not be in a position to note the tightness of the cylinders in a hydrostatic test. This being so, and in view of the importance of perfect lubrication, it does not seem out of place to make an arbitrary rating which will enable the purchaser to reach a conclusion which will reflect the life of the motor. The hydrostatic test is not so important to him, because he will be able to fall back on the makers' guarantee, if, after purchasing, the cylinders prove to be defective.

Noise, for illustration, is only rated at 25 points; this seems to be very low, and it would be, were the purchaser dull of hearing. If a motor is noisy the purchaser will be justified in the belief that it is far from mechanically perfect, and he would naturally not care to make an investment. Within certain limits, only, is a purchaser likely to deal in a noise problem, and considering this fact, the noise rating may be put down to a low level.

In the suggested system of ratings, the quality of material was not included. This would have been a very important matter two or three years ago, and from the makers' point of view it is always likely to be a serious matter. The purchaser, however, has no way of knowing the quality of the material used in a given motor, and he must be satisfied with the history of the make of car he decides to purchase, which history is represented in the five points allowed for each year of service the motor may have behind it. This allowance seems to be low, but the materials which can be purchased are all that can be used, no matter who builds the motors, and it is cheaper for the makers to use good selections rather than to risk reputation on the other kind.



Exhaust Side of Lozier Four-Cylinder Motor



Rainier Has Separately Enclosed Valve Springs

Material will have to be handled by the maker, and the purchaser will have to be satisfied to accept the maker's guarantee on this point. Under the circumstances, it would seem useless to include materials in the point system, unless the purchaser can induce the maker to state definitely what the character of the materials are, and in terms which will be understood.

High-Vaulted Armory in Which Baltimore Show Was Held; in the Foreground Appear Mitchell and Stearns

BALTIMORE, Feb. 27—The Baltimore Show, which closed last night after being the center of attraction for five nights and four days, will go down in the city's automobile history as the greatest event of the kind ever held in this locality. It is estimated that not less than 40,000 persons paid their way into the Fifth Regiment Armory to see the big display. And it should be said right here that by all the visiting tradespeople, as well as local automobilists and dealers who have attended shows elsewhere, the Fifth Regiment Armory is considered one of the most suitable buildings for holding a real successful show. Although the exact figures cannot be had because of the tendency of some dealers to keep their sales secret, it is declared by the show officials that they were close to the $250,000 mark.

Although there were only two airship exhibits at the show, they were a new feature here and attracted considerable attention. These were the monoplane of J. H. Smedley, of Connecticut, and the biplane of two Baltimoreans, Dr. Charles S. Evers and William W. Southhard.

Constructive Features of Los Angeles "Dish"

EXPERIENCE with circular tracks to unit radius is but slight, although the principle has been incorporated into bicycle track work, and has always obtained, to some extent, in connection with race tracks in general. It is anticipated that this phase of the circle idea will serve the ends better than will be possible under ordinary conditions, for the reason that the radius of the curve will be greater than that which obtains in tracks composed of curves and tangents.

This will only be true if the radius of curvature of the circle is actually greater than the radius of curvature of the turns in tracks in general. In this case, the track is one mile in circumference, so that the radius of curvature is 840 feet, approximately. This means, however, that the automobiles, when traveling on this track, will always be under the influence of centrifugal force, to whatever extent their weight and speed, considering this radius, will induce—it is probably but slight.

The Indianapolis Speedway differs from the Los Angeles "Dish" to the extent represented by a plan which includes four tangents and four curves. In the Indianapolis undertaking the radius of curvature is minimum at 840 feet. This information permits of making a comparison which will show one point, *i.e.*, the centrifugal force will be greater when a car is making a curve on a track the radius of which is 840 feet than it will be on a track the radius of which is 1,684 feet. This does not necessarily mean that the speed of travel will be very much restricted considering the track of the shorter radius, because the minimum radius considered may not be sufficiently short to seriously influence the car performance.

The illustrations here given are sufficient to clearly bring out the points of construction, and for the rest the banks are uniform for the entire distance of the course in which the vertical height of the outer circumference is 14 feet 6 inches above the dattum line. The surface is made of 2 x 4 scantlings laid on edge, running lengthwise, and quite securely bound. It was the aim of the designer to give to this surface construction the characteristics of a flattened arch, with the idea that the underpinning would scarcely play a part. It is claimed that the surface structure would remain in place, unaltered, and sustain the required weight, were the supports extended between bents.

The grandstands are elevated 4 feet above the track, and the intervening space is a strip 4 feet wide for the entire front distance. A heavy timber construction faces the grandstand, and every provision seems to have been made, not only from the point of view of the safety of spectators, but the contestants as well. The grandstand and bleachers are only five rows deep.

The construction is progressing quite as favorably as could be expected, in view of the difficulty involved in procuring lumber which comes from Vancouver. The illustrations will tell of the progress already made, but there is still a shortage of perhaps 500,000 feet of lumber, and Constructor Prince, with his army of carpenters, eats up each shipment of lumber as fast as it comes in.

CROSSING THE ATLANTIC WITH AN AUTOMOBILE

DIFFICULTIES in the way of transporting an automobile in running order across the Atlantic for a European tour were formerly regarded as almost insuperable; most persons preferred to buy or rent foreign cars after they had reached the other side. Part of these difficulties were due to the failure of the steamship lines to realize the importance of automobiles as an article of freight, and part to the ignorance of the private owners of the various formalities required in the conduct of international traffic. The steamship companies have thoroughly reformed, however, and now offer every facility. Customs formalities and others have been considerably mitigated, and, if desired, can be conducted through the agency of any one of several clubs and corporations.

Thousands of American cars are now taken abroad every year, and each automobilist who tours in this way one Summer is sure to send several others across the next. As a way of enjoyably spending a vacation, and as a means of seeing the countries visited, touring *en auto* needs no further commendation. This season is sure to bring forth more tourists than ever before, and those of the number who are making their first trip will doubtless be glad of all the information and advice that can be offered.

As to the first requisite of an automobile tour, the automobile, little need be said. It will be taken for granted that the machine in question is of proved reliability, and ready for the hardest usage. The perfect roads of France and many other European countries tempt those who like to have the throttle just a trifle wider open than the other fellow, and the strains of long-continued high speed are apt to prove more disastrous to engine and running gear than the roughest American travel. Unless the car is of one of the makes which maintain foreign branches, ample supplies of spares should be taken along, to be ready for any contingency. If it is new this season, delivery should be secured far enough in advance, not only to secure against possible delays, but to run the machine several hundred miles and so to become acquainted with it and its peculiarities.

Little trouble may be expected from the various regulations covering automobile construction. Safety from fire and explosion, effective steering, two sets of brakes and simplicity of control are features of every machine with which one would be likely to attempt a European tour. The driver must be not less than eighteen years of age, and must give satisfactory proof of his ability to handle the car. These are the international rules adopted last Fall by France, Germany, Italy, Belgium, Bulgaria, Roumania, Montenegro, Servia and Monaco. In England, which is conspicuously absent from the list, the regulations are practically the same as in most States of this country; that is, any car can be used, providing the necessary fee is paid and the number carried, and any one can secure a driving license, also on payment of the proper fee.

A single certificate is good in any of the countries listed above as using the international rules, and the certificate can be secured in any one of them convenient to the tourist. In most cases this will be France, both because this is convenient in position, and because of the assistance afforded to the tourist by the Touring Club de France. The various examinations cannot of course be taken until arrival, but through the intermediation of the Touring Club they can be arranged for and the minimum of time wasted.

The customs deposits required before entering various countries can also be made with the Touring Club, which issues international *triptyques,* or certificates. Further than these none of the European countries have any formalities which affect the transportation of automobiles. Unless care is taken to observe the American formalities, however, the tourist on his return will find himself held up for payment of duty before he is allowed to land in his home country.

Most likely to affect the pleasure of the automobilist after his arrival on the other side is the care taken in boxing the car on this side. Satisfactory work in this respect requires no little planning. Few people appreciate the rough treatment which crated articles are likely to receive in loading and unloading. The railroad "baggage-smasher" is a familiar example of what a single man can do to a trunk or similar article; the steamship packers, with the assistance of steam cranes and derricks, can accomplish much the same result with a two-ton automobile. The crating must be done with this in view.

The accompanying drawing shows in longitudinal and lateral section a crate of ample proportions; it will be observed that the framing is considerably more substantial than would be required in the case of a house or shed of similar size. Three heavy beams or skids form the foundation; of these the outer ones are 4 by 6 inches, and the middle one 4 by 4. These are united at each end by a 4 by 4 cross-piece, and by three or four 2 by 4 pieces spaced between, corresponding to the joists of a house.

The vertical risers, or studdings, are 4 by 4 timbers at each corner, and three 2 by 4 pieces on each side. These may be braced by one or more diagonals, if desired, though this is not shown in the drawing. The risers at each corner are joined by 4 by 4 timbers all around. Thus every edge of the crate is a 4 by 4, or heavier. The top has three or four 2 by 4 cross-pieces. Good firm lumber should be used.

For the covering of the crate nothing less than one inch planking will do; this may be in any suitable width. For the top, as shown, in the drawing, 1½-inch material may be used to advantage, in the event of heavy articles being dropped on the top. The bottom planking is protected by two sets of cross-pieces, which in this case are on the outside. In putting the crate together it is well to consider the possibility of using it for the return trip. By a little forethought it may be made possible to have the crate "knocked down" into compact form and stored during the trip. In most cases this will save considerable expense, but of course is not worth while if the return is to be made by a port very far distant from that of entry.

To this end the crate should be considered as composed of six separate pieces, each forming one side. The plank covering of each side can be nailed down to the beams of that side, thus uniting them. Where the beams are joined together, in assembling the several sides, through bolts should be used, both for the sake of strength and for ease in disassembling. This may add slightly to the cost of construction, and it is for the individual to decide whether this is justified in his particular case. In many places iron corner pieces can be used to advantage. The drawing shows the planking for the ends nailed directly to the end verticals; this can be avoided by the use of a couple of vertical planks joining the planking together. The ends can then be bolted on as a whole. This also facilitates removing the car when the destination is reached.

After the crate itself is constructed, the installation of the car is a matter in which no little ingenuity can be exercised. It is necessary to preclude absolutely the possibility of the car breaking loose, no matter to what treatment the crate is subjected. Many steamships have hatches too small to admit a large automobile right side up, and so must lower the crate end on. Not infrequently it is stored during the passage in the same position. The reasons for solid fastenings may then be appreciated.

The drawing shows a method which has been very successful, but individuals are cautioned against adopting it, as it is the subject of a United States patent granted to Edward Weinacht, of the Morris European Express Company, New York City, and used exclusively by that company for the crating of automobiles. The object here is to show the requirements of the case, in order that those who propose to do their own crating can act accordingly. According to this method, the wheels of the automobile are supported clear of the floor by blocks placed under the hub caps, and resting directly on the two main base pieces of the crate. The upper sides of the blocks are suitably recessed to take the hub caps, and are provided with heavy iron straps to bolt over them, thus securing the car. To add even greater security, diagonal pieces are wedged in between the axles of the car and the end cross-pieces of the crate.

For the automobilist who must devise his own method of fastening little advice can be given without the details of the car dimensions and construction. In most cases the plan must be worked out separately for each car. Knowing these requirements, namely, that the car must be so firmly supported as to become practically a part of the crate, a good carpenter can usually give a satisfactory solution.

Another method which is not patented, but the success of which depends largely on the car design, may also be described. Two pairs of internal cross-pieces are provided; one piece passes above and one below the frame of the car at both front and rear ends. The front frame extensions which form the spring hangers offer a convenient support at this end, the cross-pieces being passed between the spokes of the front wheels. The same method may usually be followed at the rear end, provided the car has semi-elliptic springs in the rear with long hangers. If not, the cross-pieces may be passed between the spokes of the wheels, one in front of and one behind the axle; the pieces being made of such width or so spaced that they are firmly wedged in. The cross-pieces both in front and rear may then be attached to the vertical studdings of the frame, which of course would be suitably spaced for this purpose. The cross-pieces, of course, should be padded where they come in contact with the car, so as to avoid marring the finish. This plan is merely a suggestion, but even if it cannot be adopted bodily it may help the individual in arriving at a satisfactory solution.

One highly desirable result is the support of the car weight clear of the tires. Standing in one spot for a week or two does not improve tires anyway, and many garages have arrangements for jacking up cars that are to stay more than a day or two. But in ocean travel the constant vibration and tossing of the ship is sure to develop a little looseness in the fastenings, and so cause the car to move to and fro slightly. This motion, if long continued, will chafe the tires in such a way as to weaken them materially, even if a blowout is not caused at the time.

Common sense requires that all moveable parts of the car should either be packed separately or so firmly fastened in place that there can be no danger of their coming loose. Seat cushions are especially offenders in this line, and are the more troublesome as few would suspect them. Tools, too, are apt to break loose. All gasoline and oil should of course be drained from the tanks before packing, as the steamship companies will not allow the former on board their vessels.

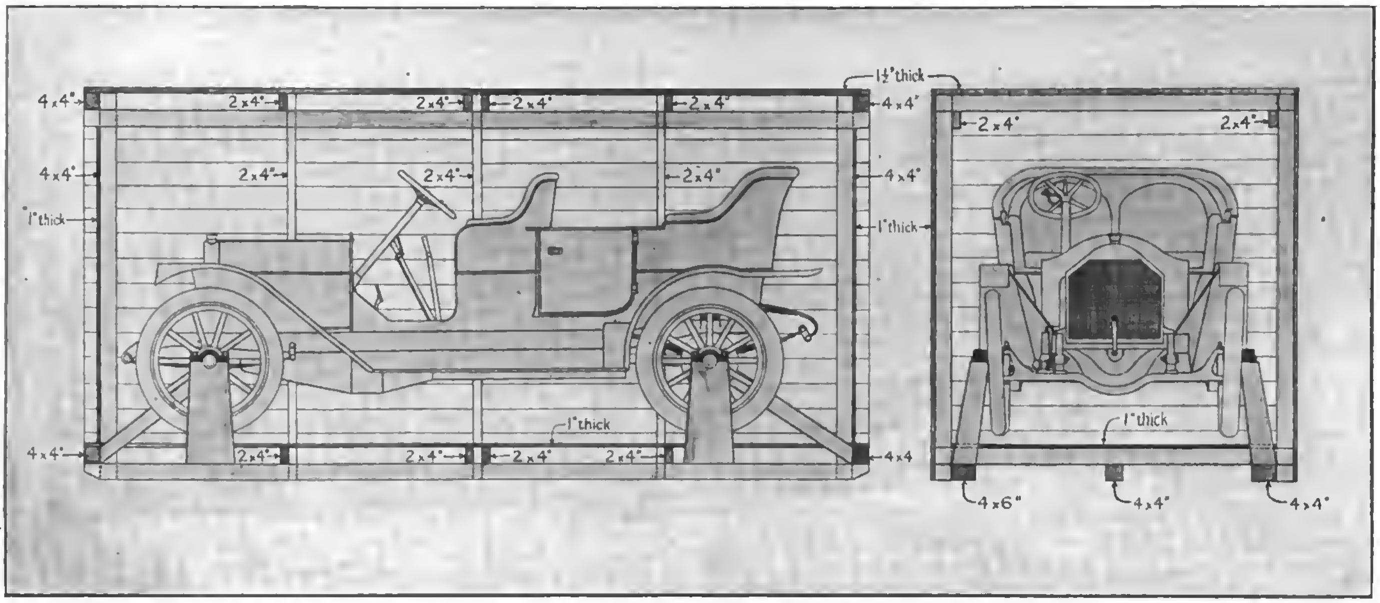
The dimensions of the crate naturally depend so much on those of the car that they cannot be indicated here. Tops and windshields should be taken off and packed as closely as possible. In general, for a car of about 120 inches wheelbase, the material required will be: 32 feet 4 by 6-inch timber; 104 feet 4 by 4-inch; 126 feet 2 by 4-inch; 434 feet (board measure) 1-inch planking, and 112 feet (board measure) 1½-inch planking.

The weight of the crate is a matter of indifference, for the reason that rates on automobile shipments are either made specially for the case, or else, under the "ship's option" privilege, are assessed not on tons of 2240 pounds, but on measurement tons of 40 cubic feet. On the latter basis the shipper will find himself rated at some 20 tons anyway, which leaves a pretty safe margin above the weight of the car itself.

One matter which should be called to the attention of those who intend to ship their cars by railroad to New York, there to be transferred to the steamer, is the custom of giving free lighterage on carload shipments. The railroad and steamship terminals at New York are so widely scattered that the cost of transfer between them often costs more than the freight itself. If an entire car is engaged for the railroad trip, which is often necessary anyway, the shipper is entitled to free transport or lighterage to any steamship pier in New York harbor.

The name and address of the shipper, and the destination, together with the words "touring automobile" or others equivalent, should be marked plainly on at least two adjacent sides of the crate. It is advisable not to mark them on with a brush, but to use a stencil with block letters clearly cut.

Nothing definite can be said about the freight rates which the prospective tourist will be called upon to pay, for the reason that these vary considerably from time to time. It will always be found advisable to have rates directly quoted by the steamship companies themselves, for an automobile of given over-all dimensions, and thus avoid misunderstandings.



Substantial Crate for Automobile Shipment, Showing Application of Weinacht Patent Car Supports Under Axles

FROM THE EUROPEAN MAIL

Flood Stops Work in French Shops

Paris, Feb. 21.—Seventy-five per cent. of the automobile factories in the neighborhood of Paris were entirely closed down by the overflowing of the River Seine or stopped for lack of pure water and light. In the majority of cases the stoppage was directly attributable to their buildings being entirely or partially under water. For ten days 15,000 to 16,000 workmen in the automobile industry alone were without employment, and the damage amounts to several thousands of dollars. The monetary loss is not confined to the manufacturers, but is shared by their workpeople also, most of whom live near the river banks and have lost clothing and furniture in the floods.

At the present time all danger appears to be past, the water having settled so much that work has been partially resumed in several factories and preparations made for driving out the floods in the others. Within Paris the only firms to entirely escape the floods are Panhard and Delahaye, both of whom have their works on high ground far removed from the river. Except for a shortage of pure water, nothing interfered with their normal working. Mors, within the city, had to close down for ten days, with a couple of feet of water in most of the shops; it was impossible to reach the factory entrance except by boat. Sizaire-Naudin, in the immediate neighborhood, had little water within the shops, but such a quantity at the entrance that no workpeople could enter and no finished goods depart.

Most of the factories are situated on the banks of the river just below Paris, and it was here that the greatest damage was done. Renault had to close down entirely, all the surrounding country being under water. The river has now retreated, leaving behind a certain amount of water and still more mud. This is being pumped out and cleaned away, and the shops are being opened up as they become fit.

Gobron-Brillié, having everything on the ground floor, and practically on the river level, had to go under to the depth of four or five feet. Darracq, Saurer, Unic, Mercedes and Charron, all grouped together by the river side, had water in their shops for ten days at a height varying from two to six feet. De Dion-Bouton sought to fight the flood with pumps and motors, but seeing that the task was impossible beat a hasty retreat, raising the dynamos onto temporary platforms, moving the chassis to the rearmost buildings, and carrying whatever machinery could be transported to upper stories. Then the water rushed in, covering most of the shops to a depth of five feet and throwing almost four thousand workpeople into temporary idleness.

Clément-Bayard had six feet of water along the new highway leading to its fine factory. As the river-front buildings, however, are mostly given up to the workmen on the ground floor, the damage was not considerable. One of the steam engines was put out of business, but by building up temporary walls the other was kept in condition and work carried on without much difficulty. Anzani had fortunately removed from the river side to larger premises further inland. The experimental plant and stock left behind were utterly ruined.

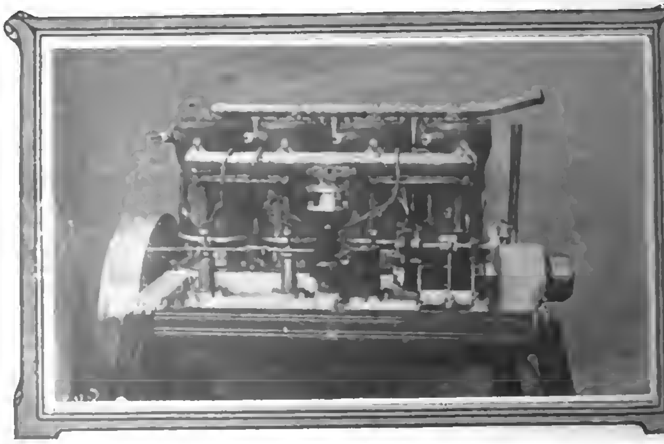
Further down stream, at the Hotchkiss, Delaunay-Belleville, and Aster establishments, considerable damage was done. The greatest sufferer, however, appears to have been Gnome, whose factories were completely submerged by the breaking of a dam. Many new American and English machine tools recently installed for the manufacture of aeronautical motors must have been almost entirely ruined by their fortnight's submersion. The Bosch magneto plant went under to such an extent that all business had to be transferred to the Lyons and other European factories. Nilmélior, among the magneto men, suffered badly, and Continental among the tiremakers.

Joint Auto and Aero Salon in Paris

Paris, Feb. 21.—In their determination to be free from the control of the Automobile Club of France, all the leading automobile constructors have decided to join with the aeronautical manufacturers in the holding of a joint automobile and aero show in the Grand Palais from October 15 to November 2. The aero salon was decided on and the date fixed several months ago, the event to be controlled, as last year, entirely by the manufacturers, without the assistance in any way of the Aero Club or other aeronautical associations.

The combination show is of recent date, and is the outcome of a failure of the automobile manufacturers to come to an understanding with the national club on the control of the annual salon. Possessed with the idea that the club did not adequately represent them as manufacturers, such leading firms as Panhard, Renault, Brasier, Grégoire, Delaunay-Belleville, Peugeot and Turcat-Méry broke away from a trade association under the tutelage of the Automobile Club of France and established the Syndicate of Constructors, to which only car constructors should be admitted, to the exclusion of accessory dealers, tiremakers, agents, body builders, etc.

This group had made a show in Paris impossible last year, but having learned that an annual exhibition is to their benefit, decided to hold one this year on reformed lines. They insisted that the joint committee responsible for the last eleven shows should be so transformed that the Automobile Club of France and its allied associations should be in a minority compared with the actual manufacturers. The club offered to retain only the same number of members as the new manufacturers' association, and to admit the cycle manufacturers, who would thus have a casting vote. The manufacturers refused to agree to anything less than the total submission of the club. This being refused, they approached the aeronautical constructors, who had already made arrangements for their show in the Grand Palais, and agreed to throw in their lot with them. Unless, therefore, the club consents to climb down and organize an automobile show on the lines dictated, this year's Grand Palais will be a combination salon



Germain (Belgian) 100-Horsepower Motor for Dirigibles

The manufacturers have nothing to lose by their persistence in refusing to hold a show with the Automobile Club, for, as they represent not less than 75 per cent of the industry, a rival organization is impossible. The Automobile Club, on the other hand, after relinquishing all effective hold on the industry, is in danger of losing the nominal control the manufacturers are still willing to bestow upon it. If the manufacturers' joint show committee scheme had been carried through, the club would have still furnished the president and figured in the eyes of the public as the leader, although in a minority regarding management and the sharing of profits of the undertaking.

A joint show is not altogether new, for in 1908 the Automobile Club and manufacturers, who were then working together, arranged for two distinct exhibitions, one for pleasure cars only, and a second one, following immediately after, for commercial vehicles and aeroplanes. The shows were a success, although the partners felt that they were not mutually helpful, truck users having little interest in flying machines and aeronautical enthusiasts finding little to interest them in wagons and stationary engines.

Last year's aeronautical exhibition, the first purely aero show in Paris, succeeded in filling half of the Grand Palais, the other half being artfully boarded off. Taking into account the increases of business in matters pertaining to the air, it is certain that the aero section cannot be crowded into less than half of the Grand Palais, leaving only one-half for the automobile section. As in previous years they have found the whole of the large building none too spacious for them, it is difficult to understand how they will all find standing room without the use of an annex.

Voiturette Stroke Again Unlimited

Paris, Feb. 21.—No limit will be placed on the stroke of the small cars taking part in the next voiturette race, scheduled to be held over a distance of 350 to 400 miles on Sunday, June 19. Two years ago the bore was fixed and stroke left unfettered, the result being that cars were produced with single-cylinder motors having a ratio of stroke to bore of 2 1-2 to 1, or 3.9 inches bore by 9.8 inches stroke. Believing that the reasonable limit of long stroke had been attained, the organizers last year limited both bore and stroke, although still maintaining the ratio of 2 1-2 to 1. The change displeased small car specialists, some of whom declared that there was no further incentive to progress, and declined to take part in the race.

This year the old rules have come into force again, the bore of the small racing cars being fixed at 3.9 inches for one cylinder, 3.1 for a twin, and 2.5 inches for a four. The weight limit has been slightly increased to 1,433 pounds, with two-seated body, but without gasoline, oil, water, or spares. Demountable rims and wheels can be employed, and the mechanic can relieve the driver during the race if desired. No outside help must be given.

The race, which has always been won by a single-cylinder of

Four-Cylinder Horizontal Aero Motor Made by Miesse

A Berliet Pumping Out Photographer Branger's Cellar

3.9 inches bore by 9.8 inches stroke, will probably this time be captured by a multiple-cylinder model. Designers are generally of the opinion that they have reached the limit in long-stroke single-cylinder models, but that there is still much to be learned in four-cylinder models with a ratio of stroke to bore that has not previously been thought practicable. Proof of this is found in the fact that one of the single-cylinder long-stroke specialists, who has been victorious in this race, is about to put on the market a commercial model having four cylinders of 2.7 inches bore by 6.6 inches stroke. This is practically a ratio of 2 1-2 to 1, hardly thought possible with racing cars two years ago.

If a motor with such a long stroke can be placed in the hands of the general public, what may be expected of the firm's racing models?

On the day following the race for the small speed monsters a speed test will be held over the same course for the same class of vehicle as sold in quantities to the public. The comparison will be interesting, for it will allow the public to judge of the respective merits of the special long-stroke cars and the medium standard models. If care is taken to see that the stock models are really assembled from series, it will give an excellent opportunity of comparing the special and the ordinary output of the firms competing.

French Imports and Exports Increase

Paris, Feb. 21.—Although French automobile business with the United States has been steadily diminishing for the past three years, the official returns show that 1909 has been a record year in the matter of exports, surpassing even the high-water mark of 1907. During the past year America cut her expenditure for French automobiles by $600,000, and diminished them by $800,000 as compared with 1906. The dimunition can only be attributed to the development of the home industry.

It is the increase of business with England, Russia, Argentine, Belgium and Germany which allowed France to reach the record figure of $29.323,000 for the 12 months of 1909. The figures for the past five years are are as follows:

Exports.		Imports.	
1905	$20,104,200	1905	$879,200
1906	27,570,800	1906	1,721,000
1907	29,072,800	1907	1,736,000
1908	25,459,800	1908	1,281,800
1909	29,323,000	1909	1,505,000

Although the exports have gone up, the imports, too, have increased, at least with relation to the preceding year. Germany and Italy, who formerly succeeded in selling a considerable number of cars in France, have given way to America, with Belgium and England in the rear.

MERITORIOUS IDEAS FROM ABROAD

Relation of Bore and Stroke

In the attempt—successful, by the way—to prove the absurdity of some of the catalog horsepower ratings in vogue in France, *Omnia* publishes an extensive list of cars on the French market, together with the bore and stroke of their cylinders. American readers, however, will be much more interested in the relations between the bore and stroke revealed by some of the figures.

Among the small four-cylinder cars rated at 10 horsepower are the Sinpar, cylinders 65 by 90 millimeters bore and stroke; Isotta, 65 x 100; Le Gui, 65 x 120; De Dion, 66 x 100; Hurtu, 70 x 90; Cottin-Desgouttes, 70 x 100; De Bazelaire, 70 x 110; Corre-La Licorne, 70 x 120; Cornilleau, 70 x 130; Luc Court, 70 x 140; Zedel, 72 x 110; Werner, 75 x 100; Vivinus, 75 x 110; Rapid, 80 x 130. Among the small six-cylinder cars are the Ariès, 60 x 110; Bazelaire, 70 x 110; Luc Court, 70 x 140; Delaunay-Belleville, 72 x 105; Bazelaire, 75 x 110; Ariès, 75 x 120; Peugeot, 80 x 110; De Diétrich, 80 x 120; C. G. V., 80 x 120; Clément-Bayard, 80 x 120; Cottin-Desgouttes, 80 x 120; Grégoire, 80 x 120; Napier, 82 x 127; Unic, 85 x 120; Delaunay-Belleville, 85 x 120; Brasier, 85 x 140.

Especially startling are the dimensions of the Luc Court, made in four- and six-cylinder models with cylinders of 70 millimeters bore by 140 millimeters stroke (2.76 by 5.52 inches). In the list of 58 six-cylinder cars there are but two in which the bore exceeds the stroke; namely, the 90-horsepower Napier, cylinders 6 by 5 inches, and the Rossel, with cylinders 120 by 110 millimeters. On three cars the bore and stroke are equal, the 110 by 110 Rossel, the 120 by 120 Darracq, and the 140 by 140 Itala. The longest stroke found on a six-cylinder car is 160 millimeters (6.3 inches), on the 50-horsepower, 100 by 160 Renault. Other examples of the long stroke are the 90 by 130 Panhard and Gladiator and the 90 by 140 Argyll (English).

Hydrogen for Dirigible Balloons

French military authorities have had a new problem brought before them: how can hydrogen be provided for the military dirigibles in case of war? *L'Automobile* of January 15 has a serious discussion of the question by Jean de Raicevich, parts of which are quoted:

"It has been suggested that the Government draw up a map of France, indicating the location of chemical plants which might, in case of need, furnish hydrogen for our dirigibles. We doubt whether many would be found. Even if there were quite a number, however, the problem would be far from solved, for between the generating of the hydrogen as the product of a chemical reaction and the compressing of it in the steel tubes used for transporting it there is a considerable gap. And after the hydrogen is suitably prepared a service of automobile trucks or railways will be necessary to carry it to the point where it is needed. Capazza affirms that such a service has been organized in Germany. It is possible, for the chemical industries are much better developed on the far side of the Rhine.

"Some figures will suffice to give an idea of the difficulty of transporting hydrogen. The steel bottles in which it is stored weigh about 9 kilograms to the cubic meter of gas (2-3 pound per cubic foot). It is easy to see at what result one would arrive for the reinflation of a dirigible of a capacity of some thousands of cubic meters. For the average dirigible about half a dozen five-ton trucks would be required to transport sufficient gas."

New French Alloy of Aluminum

A complex alloy of aluminum is described by the French journal *L'Electricien* which can be used as a bearing metal in place of brass and bronze. The ingredients are, besides aluminum, antimony, copper, tin, lead and zinc, and the following proportions are recommended: Copper, 1.2 per cent.; tin, 12 per cent.; lead, 0.8 per cent.; aluminum, 35 per cent.; antimony, 10 per cent., and zinc, 41 per cent. The extreme limits are: Copper, 0.4 to 1.25 per cent.; tin, 10 to 15 per cent.; lead, 0.6 to 0.85 per cent.; antimony, 6 to 10 per cent.; aluminum, 15 to 35 per cent., and zinc, 30 to 55 per cent.

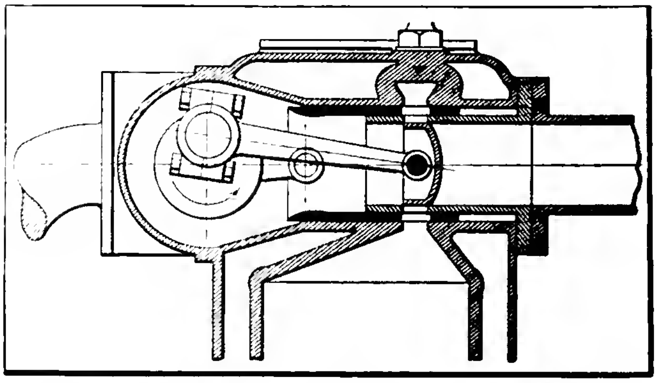
The mixing is accomplished by first melting the copper and adding the other metals one at a time. At each new addition the mixture must be stirred energetically with an iron bar and the fire allowed to go down a little. Toward the end of the operation the mixture is stirred no longer with the iron bar, but with a stick of willow or elder wood, which gives a more uniform mingling and accentuates the properties of the metal.

Drummond-Bostock Piston Valve

Another example of the ingenuity with which English inventors are attacking the valve problem is the system invented by C. E. Drummond and F. J. Bostock, described in *Automotor Journal*, February 5. This valve works in more than theory, for a De Dietrich car so fitted has been on the road since last June.

The valve for each separate cylinder consists of a piston and a sliding sleeve in which the piston works; they are disposed horizontally across the head of the cylinder, and are actuated by a miniature crankshaft lying alongside the cylinders. This shaft has two cranks for each cylinder, one connected with the piston and one with the sleeve. The sleeve cranks are about a quarter of a revolution ahead of the piston cranks. The inlet and exhaust gases pass through the same opening in the head; the combustion chamber is elongated so as to form an annular pocket surrounding the valve mechanism. The idea is that during the compression and expansion strokes the opening is made tight by the sleeve, which is then at the outer limit of its travel; during the exhaust and inlet strokes the sleeve opens a passage, and the direction taken by the gases is then determined by the position of the piston valve.

The housing of the valve crankshaft is utilized as the inlet manifold, the gas being drawn around the lower end of the piston valve, which is then on the outer part of its stroke. The exhaust passes out over the head of the piston valve directly into the exhaust manifold. It will be seen that to maintain tightness it



Drummond and Bostock Valve Idea, with Piston and Sleeve is only necessary to insure that this condition exists around the sleeve. To this end it is provided with external piston rings on its inner end, and internal rings on the outer end surrounding a stationary sleeve. But a very small amount of power is required for driving these valves; in the experimental car the valve shaft was connected with the crankshaft by a chain, and a 1-2 inch size was found perfectly satisfactory for this purpose.

Like most devices of the kind which have been brought out, this valve system lacks the cardinal virtue of simplicity. It has practically the same number of parts as the Knight valve, the difference being that one of the Knight sleeves becomes in this case a piston. The operating crankshaft and the connecting rods are exactly the same. In action it may be expected to be quite silent and to give ample valve openings.

Torbinia Hydraulic Transmission

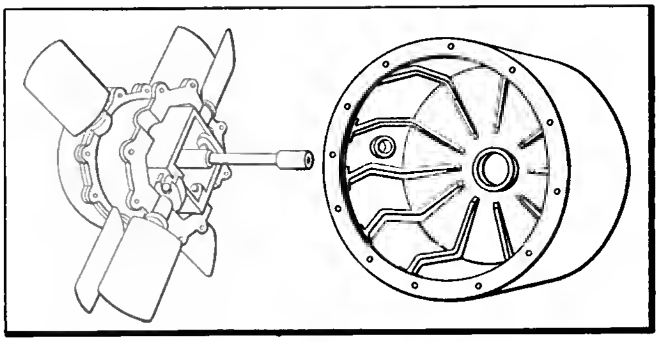
This new form of an old idea, which made its first appearance at the Olympia show at London, is the subject of an interesting article by T. C. Salsbury in *La France Automobile.* It is distinguished among similar devices by having neither pumps, pistons nor valves.

The principal elements of the device are a drum or cylindrical chamber of aluminum, provided on the inside with radial ribs, in which rotates a hub with a double series of blades which can take any pitch angle from zero to 90 degrees. Each set of the blades is practically the same as one of the reversible propellers commonly used on motor boats. When these parts are assembled the case is filled with a mixture of six parts of water to one of oil. The propellers being attached to the motor shaft and the drum to the drive shaft, the power is then transmitted by the drag of the liquid, set in motion by the propellers, on the ribs of the drum.

When the propeller blades are set at right angles to the axis of their shaft—with a pitch angle of zero, as it were—their movement is practically free, and the motor is running light. Giving the blades a slight pitch angle, by means of suitable linkage, enables them to set the liquid in motion, and so turn the drum and the drive shaft. When the blades are set at their maximum angle of 90 degrees, the adjacent edges of each pair meet, making one continuous blade or paddle. As the clearance between these paddles and the ribs of the drum is very small, this amounts practically to a positive direct drive.

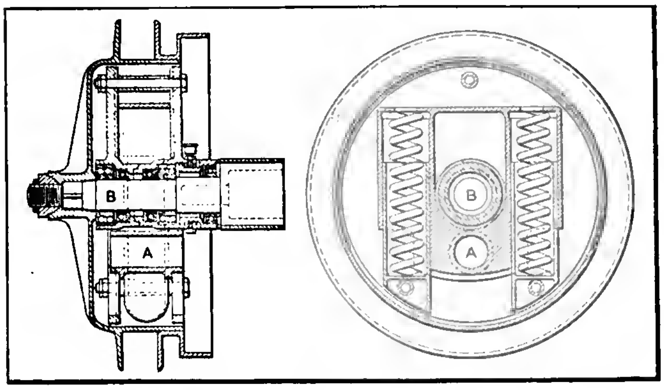
The great novelty and merit of the device is the arrangement of the propeller blades in pairs, with each of the pair working in the opposite direction from the other. In this way the end thrusts which would be set up by the movements of single blades are eliminated. At the same time the high-speed arrangement gives a more positive drive than has ever before been secured with such apparatus.

It is rather surprising, however, to learn that despite the excellence of the theory the makers of the "Torbinia" car, in which this device is used, have found it necessary to provide a low gear of the ordinary sliding type. They found that at low speeds the



Drum, and Paddles with Operating Mechanism, of Torbinia

friction of the blades, moving through the liquid with a very flat angle, absorbed so much power in proportion to the disturbance they set up that it was impossible for a car to pull out on a hill from a standing start.



Genillon Wheel, Rigid, but Flexibly Suspended from Hub

Genillon Spring-Suspended Wheel

This wheel, which is described in the French journal *Omnia,* issue of January 22, is distinctly not a spring wheel in the usual sense of the term. The wheel itself is perfectly rigid, or the usual construction, and is provided with a solid rubber tire. The flexibility and elasticity is all in the attachment of the wheel to the hub. As may be seen best from the drawings, it is in reality suspended, the hub being several inches below the center of the wheel. The load is carried by a pair of stout coil springs, acting in compression. This construction is particularly adapted to live-axle systems in which the weight is carried by a solid axle entirely separate from the driving mechanism, such as that of the De Dion cars.

M. André Walter explains the merits of the wheel as follows: "Every time a wheel meets an obstacle it undergoes a reaction, directed toward its center, which may be divided into horizontal and vertical components. With ordinary suspensions the vertical component alone results in a movement of the wheel, which surmounts the obstacle without slowing perceptibly its horizontal motion. This horizontal reaction is transmitted to the chassis, which by its weight immediately overcomes it. In reality, this horizontal component, the effects of which are not noticed by the passengers of the car unless the height of the obstacle is several inches, nevertheless has a very destructive effect on the wheel and its tire.

"With the Genillon wheel things are quite different. When the wheel meets an obstacle it checks its speed slightly, although the body of the car, by virtue of its inertia, continues at the same speed. This relative movement between the wheel and its hub, which continues with the body of the car, compresses the spring mountings, and when sufficient force is exerted, causes the wheel to leap quickly over the obstacle, coming down, not behind, but ahead of the hub. On account of the increased distance between the center of the wheel and the hub, the body of the car has a very slight vertical movement; its inertia carries it on in practically a straight line, irrespective of the movements of the wheel.

"There is one difficulty, however, when the wheel, meeting an obstacle, slows down with respect to the chassis, its speed of rotation must diminish quite noticeably for some moments, again becoming normal after having made up for lost time by a temporary acceleration. In the case of a front wheel, this makes little difference; but in the case of a driving wheel, the wheel must either slip or the motor and transmission system must follow the variations of speed, multiplied as they are by the gearing. In practice the wheel would probably slip, and the damaging effect of such action on the tires would compensate for any saving that might otherwise be secured. It is to be hoped that the inventor has foreseen this difficulty and provided against it by some means as ingenious as the very clever arrangement of the spring wheel itself. This arrangement should find favor for truck use."

Criticises T. K.'s Airship Scheme

Editor THE AUTOMOBILE:

[2,183]—In your issue of Jan. 20, containing letter number 2,143, T. K. Pittsburgh submits some ideas relative to aerial navigation worthy of study and investigation. In his over confidence, T. K. has taken for granted certain desired results, without reckoning the serious points of opposition. First, his idea of utilizing the combined effect of a horizontal rimbound propeller with adjustable blades for the purpose of raising and balancing the machine is well taken. The gyroscopic effect for balancing has been fully demonstrated in the monorail car. A single horizontal propeller of the diameter indicated in the sketch can never become practical—the great velocity required to lift the machine would cause the same to fly to pieces or twist loose from the hub. Another trouble would be the strong tendency of the large wheel to carry the entire machine around with its own revolutions (a case of the tail wagging the dog). He makes no provision for distributing the frame and forward propeller to equalize the weight to be carried. In my opinion, the forward horizontal and vertical planes should be larger and occupy a place in the rear, and should be operated as a rudder. To obviate the tendency of the machine to revolve with the overhead wheel, two or three smaller wheels, running in opposite directions, would no doubt eliminate the trouble. To obtain a sufficient thrust to lift the device and retain a safe balancing effect, great velocity is necessary. In the absence of large horizontal planes, the lifting propellers would necessarily need to be constructed slightly conical with spaces between the blades closed to get the effect of a parachute in making a descent. The details of T. K.'s sketch are vague and many points are entirely absent. Yet, after all, there is an idea implied that can be worked out for future navigators of the air to rise from the earth perpendicularly and also to be able to stop the machine in midair and retain their position long enough to exchange messages with each other. J. U. BAKER.

Stoutsville, O.

Some of the points are well taken, thus, the matter of rotary speed of the propeller as compared to the bursting speed of the rim. The latter may not attain a lineal speed of more than 6,000 ft. per minute, if of cast iron, and about 10,000 ft. per minute, if of steel. At the comparative size of the man and some other sizes which might be assumed with safety, the flywheel-gyroscope-lifting propeller appeared to be about 60 ft. in diameter, which would give it a circumference of 188.5 ft. Dividing the permissible speed by this, the speed of rotation which the material will allow is but 32 revolutions per minute for iron and 53 for steel. It is conceivable that this speed might possibly be of use somewhere at some time, by somebody, but for flying purposes it is out of the question.

As to the location of the forward propellers, either front or rear is recognized as good practice, the one used being simply dependent upon correct balancing, and changeable at will.

The Motor Jumps and Misses

Editor THE AUTOMOBILE:

[2,184]—Will you please tell me the cause of a puzzling case of missing in my engine. It is a four-cylinder, 15-horsepower motor, and knocks or pounds on all four cylinders when I advance the gas lever to the second notch. But, when I advance it further between the second and fifth notch, it skips, and the motor jumps. Then, to advance it still further than the fifth causes it to settle down to knocking on all four cylinders again. In this latter case, it is going at a speed that is dangerous for such a light weight car. J. T. C.

Bayonne, N. J.

The pounding might be caused by too rich a mixture, which after being fed to the cylinders for some length of time, would also result in missing, through the interior of the cylinders becoming coated with a deposit of carbon. The symptoms of further pounding with an advance beyond that which causes the greatest missing, is very hard to diagnose, but the first-mentioned trouble might well be caused by too rich a fuel supply as stated. To remedy this, loosen up on the spring of the auxiliary air valve. This will allow air to enter sooner, and at high speeds and in hard going, the engine will draw in a greater percentage of air. If after this change is made, the engine still keeps up the pounding and missing, it will be necessary to attend to the adjustment of the needle valve, so that less fuel may enter.

LETTERS INTERESTING

Cylinder Carburetion Troubles

Editor THE AUTOMOBILE:

[2,185]—Will you please answer the following questions? 1. Why is it that a carbureter which will work with an engine of one or two cylinders of say 5-in. bore will not work satisfactorily with an engine of three, four, or six cylinders of the same bore. The same carbureter will work with three and four cylinders of 4 3-4-in. bore and with six-cylinder engines of 4 1-4-in. bore. 2. Will the same carbureter work with both two and four-cycle engines of equal bore and stroke, provided a check valve is used for the two-cycle? ROY WOOD.

Toronto.

Carbureters can only be changed from one engine to another when the cubical capacity of the two engines are alike. The statement that a carbureter would work equally well on motors of three and four cylinders 4 3-4-in. bore, and six cylinders of 4 1-4-in. bore, is ridiculous. The cubical capacity of a four of 4 3-4-in. bore and, say, 5-in. stroke, is 354.4 cubic inches. For a six of 4 1-4-in. bore and 5-in. stroke the capacity is 425.7 cubic inches, an increase of over 20 per cent. Surely if the carbureter was right in the one case, it would be much too small in the other, and inversely if it was large enough for the six, it certainly would be too large for the four.

Actually what must be done is to equate the cubical capacity of the cylinders of the motors in question, as the same vaporizer should be able to supply the same amount of gas to two engines of similar capacity, being otherwise different in number of cylinders making no difference. Thus, if the carbureter was right for a four-cylinder engine of 4 3-4-in. bore and 5-in. stroke, it could be used on the following engines of differing cylinders, but of the same capacity, all fours: 3 3-4 bore by 8-in. stroke; 3 7-8 bore by 7 1-2 stroke; 4 bore by 7 stroke; 4 1-4 bore by 6 1-4 stroke; 4 1-2 by 5 3-8; 4 5-8 by 5 1-4; 4 7-8 by 4 3-4; 5 by 4 1-2; 5 1-8 by 4 1-4; 5 3-8 by 3 7-8; and 5 1-2 by 3 3-4.

Four-Cylinder Engine Power

Editor THE AUTOMOBILE:

[2,186]—Will you please tell me in your columns of "Letters Interesting, Answered and Discussed," how a certain company can get 60-horsepower out of a four-cylinder engine operated with an overhead camshaft and valves inclined at 45 degrees, set in opposite sides of the cylinder heads. Same engine having a 4 3-4-in. bore and 4 3-4-in. stroke, when an engine of such dimensions is rated at 36.4 horsepower? E. G. H.

St. Cloud, Minn.

In the matter of rating, any maker is free to rate his engine as he pleases. Thus, if a manufacturer so desired, he could rate an engine of this size (four cylinders, 4 3-4 by 4 3-4) at 100 horsepower. However, the formula rating method is meeting with much favor, and makers generally are finding out that it pays to rate according to formula. Then, if their engine through superior construction gives much higher power than the formula rating, the buyer is that much ahead, and is correspondingly better satisfied. Every satisfied purchaser becomes a good advertiser, so in the long run the maker giving the most for the money (which is what low or even formula rating amounts to) is the most successful.

As to the particular construction of which mention is made, it is generally admitted that overhead valves will result in superior power from a given size of cylinders, the rest of the construction being up to a fitting standard.

ANSWERED AND DISCUSSED

Adjustment of Air Valves

Editor THE AUTOMOBILE:

[2,187]—I am a subscriber to your valued journal and have gained knowledge far in advance of the subscription price from reading it, especially "Letters Interesting, Answered and Discussed," of which I would be glad to see more. I have had a little problem of my own, which I will ask you to help me out on. I have a Buick Model 10 (1909) on which is used a Schebler carbureter. A little while back the air valve worked loose and the stem and spring dropped down into the pan underneath the motor. In replacing this stem and spring, I am not sure whether I got it back as it was before, that is, the adjustment to give the best results. If possible, please tell me how to go about it to test or correct the setting of this valve. My car is equipped with a four-cylinder 3 3-4 by 3 3-4 motor, ignition is by storage battery for starting and magneto for running. I also notice sometimes that the radiator gets excessively hot and that steam will pass out through the overflow at the bottom, although the radiator has plenty of water. Please advise what causes such a high degree of heat. F. L. TORBERT.

La Fayette, Ala.

Air valves on carbureters should be adjusted to the high speed of the engine, the needle valve to the low speed. Having the latter set to your satisfaction, open the air valve wider and wider until the engine seems to lose speed. Mark this spot so that you can return to it readily, then turn the other way, closing down on the amount of air until your engine again begins to slow down. You will then have two marked points between which the engine runs well, but do not know the exact spot which will give the best all-around results. This will be a subject for further experimentation, and your best plan will be to take an arbitrary setting and try it out both as to speed on the level and pulling qualities, on hills and in heavy going, such as sand or mud. If you find this unsatisfactory under any or all of these conditions, make another trial. Note whether you decrease or increase the air, and if this improves the general average of the motor performance, go a little further in the same direction. If it does not improve it, but, on the contrary, makes it poorer, turn in the reverse direction. All other things being equal, as much air as possible is preferable, for this results not only in more power, but in an increased economy of running, provided the speed range be within that for which the valve is set.

An Old, Old Friend Turns Up

Editor THE AUTOMOBILE:

[2,188]—Will you kindly answer the following question in your columns "Letters Interesting, Answered and Discussed," if space permits? A discussion started here a few days ago as to which wheels of a car, the inside or the outside, would leave the ground in case a car takes a turn at a high enough speed. At first thought it would seem as if the outside wheels would be the ones, but on reasoning it out, it is seen that theoretically it should be the inside wheels that would leave. On the other hand, I think there is a picture of a Chalmers car taking a turn in the last Vanderbilt Cup Race, and the outside wheels are up in the air. Can you tell me if there is any condition under which the outside wheels would leave the ground, and also explain the picture if you know of it? F. W. SEAMAN.

Swarthmore, Pa.

The inside wheels must always rise, and the picture to which reference is made (shown on page 777 of The Automobile for November 4, 1909) shows this very clearly, and not, as suggested, the outer wheels rising from the ground. In this picture, the car is coming around from the far right, the left part of the picture showing the banking of the track at this point.

All About Piston Rings

Editor THE AUTOMOBILE:

[2,189]—What is the best way to remove piston rings from pistons? Is there much danger of breaking them in removing? What is the best way to "set out" the rings? How tight should they fit in the cylinder, when the bore is 3 5-8 in., stroke 3 1-2 in., air cooled? What is the best compression for four-cylinder motors of this size? I have set out large steam piston rings with pean hammer, but motor piston rings are so small, and being of cast iron, I have thought that they might be easily broken by this method. AMATEUR.

North Adams, Mass.

In removing piston rings, lay down on the surface of the piston three or four strips of very thin flat steel. Raise the first ring out of its groove, either by expanding it by means of special tongs or by simply picking it up as best you can. Then slide the flat strips of steel under this and slide the ring along on the strips until the top is reached, when it may be picked off. The reason for the strips of steel is, first, to allow the rings to slide easily, having a uniform surface to slide on, and, second, to prevent the second and later rings from dropping into the open grooves made by the first ring. It is not always convenient to take the bottom ring off first, and even if it were done there would be the other rings to pass over, which is just as difficult as passing over an open ring space.

Cast-iron piston rings may be set out by means of a pean hammer, just as was formerly done with steel steam rings. The only thing is that the work must be done more slowly and more carefully. There are machines on the market in which the rings are turned concentric, and then made elastic enough to spring out and hold against the cylinder walls by hand-peaning on one side of the ring. The number of examples of this are few in America, but a number of French car makers use it.

The tightness is hardly dependent upon the engine size, although the clearance allowed between the piston and walls is usually proportioned to size, a matter of expansion allowance.

Types of Rear Springs

Editor THE AUTOMOBILE:

[2,190]—Will you please advise me through your columns how many automobile manufacturers have adopted the reverse rear spring? Do you not think that in time this spring will be universally adopted, as its easy riding qualities are certainly more pronounced than any other type of spring? E. G.

Montreal.

The form of spring to which the writer above doubtless has reference is that usually known as the platform spring. The reason why this is taken as the one to which reference is had is that but one rear spring is referred to, which is the case in the platform spring, the cross spring being the reverse of that usually used, that is, what is called the opening of the spring is downward, not upward.

Some idea of the number of makers using this type of spring in preference to all others for the rear of the chassis (it is never used elsewhere) may be gleaned from a table of specifications. From such a one which is handy the following figures are taken: 123 makers, with 255 different car models, used 32 platform springs. As to cars, this is just 12.5 per cent., while as to makers, it is 26 per cent. The latter figure is, however, somewhat unfair, for many of the makers used this kind on one model and not on others, so that the real percentage of makers committed to this type as the *only* one would be much less than this; in fact, much closer to the other percentage figure. From this statement, as well as the percentages, the idea may be gathered that no one type of spring can be said with truth to be superior to all others. To state this as a fact, besides lacking proof, would be to insult the intelligence of the makers using other kinds, and using them for good and sufficient reason, too.

From the same table it really would appear as if the three-quarter scroll-ended elliptic spring is held in the highest esteem just now, although this is rather a late improvement, coming into vogue as it did about two years ago.

SOME COIL TROUBLES EXPLAINED

By Stillman Taylor

ALTHOUGH the autoist may at first have some little difficulty in diagnosing troubles which not infrequently result in the spark coil failure, these puzzling matters will soon be understood as one becomes acquainted with the electrical plant and familiar with the idiosyncrasies of the sparking circuit. Coil troubles are, as a general thing, caused by short circuits, and, while the source of the failure may be due to a defect or breakdown in the coil itself, the difficulty is more likely to be caused by poorly insulated wiring, loose terminals, or some other part of the electrical system outside of the coil proper. In fact, there are a number of probable causes which are certain to affect the proper action of the coil, as may be noted from the following list of symptoms and their causes:

Symptoms:—Irregular or intermittent buzzing of the contact breaker or vibrator, metallic clatter or "tinny" sound of vibrator, as distinguished from the usual moderately high-pitched musical buzz. Buzzing sound coming from inside the coil.

Causes:—Pitted or badly worn platinum contacts, loose contact studs, trembler blade adjusted too loose or too stiff, thus affording poor contact, contacts made of inferior platinum alloy, loose terminals, dirt on terminals or coil plates, moisture on plates, defective insulation in connecting wires, defective condenser, coil punctured (insulation broken down inside).

The most prolific cause of failure is due to pitted and improperly adjusted trembler contacts, and in cases of misfiring, evidently due to some failure of the ignition system, the contact breaker of the coil is the first point to be examined. If the contacts are pitted and uneven they should be carefully trimmed up level with a "dead smooth" jeweler's or manicurist's file. In adjusting the tension of the trembler blade, avoid a loose or too stiff tension, as the former will provide a slow contact, and the latter will interfere with the proper action of the coil, and likewise rapidly pit and wear away the platinum. Good coil service cannot be had unless the tremblers of all the units are adjusted as nearly alike as possible. This matter is not always given the attention it deserves, and while an "old hand" may be able to approximate this adjustment very closely by ear, the only exact method is to measure the current consumption of the coil by the aid of a special ammeter sold for this purpose. The manufacturer's directions should be explicitly followed, and each trembler adjusted to draw the recommended amount of current.

The accumulation of moisture or dirt on the terminals of the coil is frequently the cause of short circuits, and a short circuit may also be produced by a weak place in the insulated covering of the wires. Although not always the case, a short in the coil may often be located by excessive sparking at the contacts and in some instances the short will set up a buzzing inside the coil. Excessive sparking may be caused by poor adjustment of the trembler blades, inferior platinum, and less frequently traced to a defective condenser. Proper adjustment will prove a remedy in the first case, new platinum points in the second, while a new condenser or coil will be needed if the fault is in the coil itself.

In the event that the motor develops a case of misfiring, the autoist should first ascertain if all the vibrators are breaking the circuit properly on time. This may be quickly done by turning over the motor until it makes contact with the segment of the timer. If no buzz is forthcoming, examine the wiring and terminals. If the buzz is heard, locate the missing sylinder by cutting out each one until the "dead" cylinder is found. This may be located by the lower temperature, if the motor has been running for some time, or by inserting a bit of pasteboard between the points of all tremblers but the one to be tested. When located, the trouble will generally be found to be in the plug.

In case the primary winding of the coil is suspected to be injured, the defect may be easily located by connecting up the voltmeter to the battery terminals, and, after taking a reading, place one end of the instrument in contact with the terminal of the coil. This simple test will point out any defect in the primary winding, as the current must go through the primary winding before it registers the voltage, through the voltmeter. Short circuits in the winding of the coil are naturally more likely to occur in the high-tension of the secondary wiring, but as this winding is of considerable length, the exact location of the leak can only be determined in the testing room of the manufacturer.

Failure of the condenser is not a common trouble, yet the writer has upon several occasions traced excessive sparking at the points to a grounded condenser. As the autoist may know, the condenser is connected in a shunt in the primary circuit, and if the connections are faulty the condenser may become grounded by reason of the wiring coming into contact with another wire or other conducting body. The trouble may be in either the wire leading from condenser to trembler on one side, or in the connecting wire joining trembler and condenser, or from condenser to ground, on the other side. In cases of this kind, the current cannot reach the condenser, whose function is to absorb the spark, and it accordingly passes by way of the leak or short, thus causing excessive sparking at the tremblers. As the condenser connections are made with very light wires, and as this part of the coil is apt to look very complicated to the average driver, it is best to send the condenser to the makers, in case it has broken down through internal sparking.

Some Common Tire Fallacies Exploded*

ERRONEOUS would be the best word to characterize the common notion of the first point to be raised in connection with the pneumatic tire and the manner in which an automobile is carried by it. The ordinary view of this seems to be that the wheel rests on and is supported by the cushion of air below it—the air, in fact, compressed between the lower portion of the rim and the tread of the tire adjacent to the ground. The objection to this simple view, when one comes to consider it, is that the rim of the wheel is completely surrounded by the air enclosed within the tire. The compressed air not only presses on the under side of the rim, forcing it up, but also on the upper side of the rim, forcing it down; and as the air chamber within the tire is continuous the two pressures are equal. Similarly, the air pressure on the anterior face of the rim forcing it back is equal to that on the posterior face of the rim forcing it forward. Every square inch of the rim is exposed

* Short abstract of paper read before the Royal Automobile Club of Great Britain and Ireland, by D. W. Samways, M.D., D.Sc., M.A.

to an equal number of pounds of air pressure acting perpendicularly to its surface, while the pressure on any square inch is always opposed and balanced by that on the square inch of the bed of the rim diametrically opposite to it. It is manifest, therefore, that the wheel and rim cannot be supported by the pressure of air on the rim.

To illustrate this point, the following experiment was performed: The tire of one wheel of a car weighing with its load 600 lbs. was pumped up to a pressure of 70 lbs. per sq. in, the wheel having previously been jacked up, with the air valve placed in its lowest possible position. The wheel was then turned half round, so that the valve communicated with the air chamber above the wheel. The pressure was still 70 lbs., exactly as before. The wheel was then lowered, and the tire, with its load, rested on the ground. The pressure taken with the valve inferiority was now nearly 72 lbs., a rise of less than 2 lbs. per sq. in., when the air instead of the jack had to carry the load. The same pressure of 72 lbs. was recorded when the wheel was turned half round and the record was that of the pressure in the air chamber above the wheel. The increased pressure of 2 lbs. per sq. in. on the rim beneath the wheel pressing upwards could not possibly carry the wheel, and, moreover, was rendered neutral as a lifting force because the same increase of pressure occurred above the wheel, acting equally as a depressing force upon the rim beneath it.

Of other forces acting on the rim and wheel, there remain only the tensions of the tire walls, whose free borders are fixed under the beading of the rim. The tire is exerting an immense centrifugal pull on the rim. It is trying to burst away into space, and is only held back by its walls, which are anchored to the wheel. On a wheel 870 by 90 every linear inch of the tire wall fastened under the beading of the rim, when the tire is inflated to 70 lbs. pressure, is dragging centrifugally outwards with a force exceeding 100 lbs. When, however, the wheel and tire are jacked up, this pull is equal all round, and there is consequently no reason for the wheel to show any preference to the pull in any direction. If, however, the wheel and tire be rested on the ground, the centrifugal pull of the portion of tire resting on the ground is taken off the rim. The pressure on the tread touching the ground is transferred to the ground and supported by it, instead of as before by the adjacent tire walls which attach the tread to the rim and previously dragged downward on the rim. The effect, therefore, of the ground in carrying a pneumatic tire and its load is to slightly increase the pressure and consequent tensions in the tire, and to relieve more or less completely the vertical component of the tension in the tire walls immediately above the ground. Above the wheel the tire walls continue to pull upwards on the rim with undiminished and now unbalanced force; consequently they pull up the rim, and with it the wheel and car, whose total weight exactly equals the amount of downward tension taken off from the tire walls below the wheel. A motor wheel is, therefore, in all cases suspended from above by its inflated tire. The tire is supported on the ground below it, but the wheel is hung from the portion above it, and is not carried by the cushion of air from below.

If the wheel be hung from the tire arch above it, the next point is to consider what supports this arch. Now we have been told that the air pressure outwards on the whole tread of the tire is exactly equal to the air pressure inwards on the rim of the wheel, and that these balance one another. This obviously is not the case. The tread of the tire is part of a larger circle than the rim of the wheel, and consequently has a larger surface exposed to the pressure of the air within the tire. Thus on a wheel 870 by 90 the rim measures 3 ins. across, and about 88 ins. round. The whole rim has, therfiefore, a surface area of 264 sq. ins. The tire tread measured, not at its margin, but where it also is about 3 ins. across, is about 100 ins. in length, and has consequently a horizontally resolved surface area of about 300 sq. ins., *i. e.*, 36 sq. ins. more than the whole area of the bed of the rim. If the tire be pumped to a pressure of 70 lbs. per sq in, the tread will have to support a centrifugal air pressure of 36 by 70 = 2,520 lbs. more than the centripetal air pressure which the bed of the rim is called upon to support. Of this total excess pressure of 2,520 lbs. on the tread over that on the rim, one-half, *i. e.*, 1,260 lbs., is exerted on the tread above the wheel and the other half on the tread below the wheel.

Now, the air in the upper half of the tire communicates with the air in the lower half across the two sections of tire which unite them, one before and one behind the wheel. These sections have a transverse area of about 9 ins. each, and, therefore, transmit air columns of that section, every square inch of which columns exerts a pressure of 70 lbs. That is, each air column presses upward and downward with a force of 9 by 70=630 lbs. The two columns transmit, therefore, a force or pressure of 1,260 lbs. This coincides with the amount by which we found the pressure on the upper half or vault of the tire tread exceeded the pressure on the half rim of the wheel. In this pressure scheme the wheel itself is but a frame around which the tire is bound. The wheel receives an upthrust x from the air below it, and supports a down thrust x from the air above it, which in turn exerts an upthrust on the vault of the tire of the same amount x. The vault, in addition, receives from the two columns of air spoken of a total upthrust of 1,260 lbs., which is quite sufficient to more than carry the wheel and its load.

These remarks will explain the phenomenon so frequently observed of a tire bursting in its upper half. The foreman of one of the largest Paris garages, which always contains scores, and sometimes a hundred or more cars, told that in the garage tires burst almost always in the upper half. "I speak," said he, "not of ten, but of a thousand cases." The part of a tire least subjected to strain is that between the wheel and ground.

The second question to which attention is called relates to the advantages of a high tire over a low one, especially as regards its dust-raising properties. The Royal Automobile Club is constantly endeavoring to discover in what direction we must look to mitigate the dust nuisance, and the belief is that the encouragement of higher driving-wheels would be one step in the true direction. The tire round a wheel has to support the weight of the wheel and its load, and to do so, with a given pressure in the tire, a definite area of the tire tread must be in contact with the ground. If the length of the contact surface be short, as it necessarily must be with a small wheel, the width of contact must be increased. Hence, it has been found that the small wheels at present used, especially for driving wheels, must have very wide tires. Now, it is the width of contact, and not the length of the contact surface on the ground, which determines the amount of dust a wheel raises. A wide track obviously raises more dust than a narrow one. When the wheel is high, as in some of the cars originally made, the driving wheels can easily take tires as narrow as those on the front wheels. With a high wheel the contact surface is a long narrow oval, and with a low one it is a short wide oval for the same supporting area. One comparatively light car requires tires 810 by 100 on its driving wheels; otherwise they perpetually give trouble, especially through overheating. On a much heavier car exposed to much rougher usage, are tires of 1910 by 90, and though the width of the tires is less than in the lighter car, it behaves almost as if it were over-tired. At the same time it raises much less dust at the same speed, making, as it does, a narrower track. They run much more smoothly; the tire lasts longer, as it touches the ground less often; it probably heats less and certainly cools more freely.

The third problem relative to tires, one affecting us all, is how to prolong their life. The first essential is to have as high wheels as possible on our cars. Experience shows that the life of a tire, other things being equal, goes largely with the height of the wheel, for reasons some of which have been suggested. Tires on large wheels, moreover, support better the application of the brake than those on small ones, for the friction with the ground is along the long axis of the oval surface of contact, and a longer stretch of tire wall supports the strain.

SOME TRANSMISSION MECHANISMS

In

Modern Shaft-Driven Automobiles

By Forrest R. Jones, M. E.

IN modern shaft-driven gasoline automobiles, to which type the great majority of cars now belong, the tendency is to locate the transmission either at the rear axle as an integral part of the differential housing, or as a rigid extension of the crankcase of the motor, and to use only one universal joint or coupling between the motor and rear axle in connection with this arrangement of the transmission mechanisms.

The advantages and disadvantages of these two locations of the change-speed gears are decidedly marked in each case. The use of only one universal joint, as compared with the common earlier practice of using a pair of universal joints in proper relation to each other, is also an important feature, with its own advantages and disadvantages. In both cases the reduction in the number of parts, especially wearing parts, is an important item that should never be omitted in considering such a machine as an automobile, in which lightness and simplicity are of paramount importance, and in which wear is extremely rapid. The rapid wear is due to the lightness or smallness of the parts and the consequent high pressures and speeds to which they are subjected, aside from the dust and grit which reach parts unprotected from them. The absence of dust and grit protectors is not unusual in the less expensive cars. The wear due to dust and grit is notably rapid in automobiles as compared with other classes of transportation machinery. This rapidity of wear is because the automobile travels over roads which are generally dusty or muddy, and the road wheels move so rapidly that gritty substances are constantly stirred up and either drawn or splashed over the running gear, particularly the transmission mechanism, when it is not suitably protected.

When Two Universal Joints Are Used

When two universal joints are used in a shaft transmission, one joint near the rear axle and the other near the change-gear case, the shaft which carries the bevel pinion gear that meshes with the larger gear on the rear axle is necessarily short. This short pinion shaft of course requires the two bearings which support it is to be near together. When the two bearings, both on the same side of the pinion gear, are near together, the pressure on them is much greater than when they are at a considerable distance apart. This can be seen by the aid of Figs. 1, 2 and 3.

Fig. 1 shows a shaft A, to which a load, or side pressure, of 100 pounds is applied near one end at B. The shaft is supported at C and D. The distance between B and C is 2 inches, measured parallel to the length of the shaft; that between C and D is 4 inches, measured in the same manner. The shaft may be considered as a lever, with the fulcrum at C. The pressure, or force, at D, on the longer arm of the lever, bears a ratio to the force at B equal to the inverse ratio of the lengths of the lever arms, which lengths are 2 inches and 4 inches. This is the value of the force that is necessary to hold the shaft in place. The

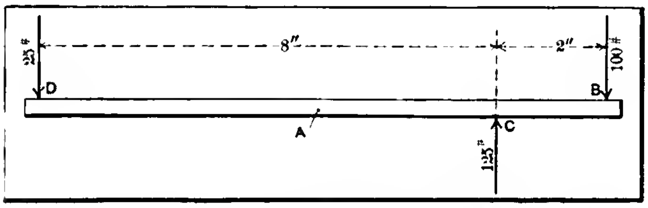


Fig. 1—Shaft with side pressure applied nearer to one end

force at D is therefore $\frac{2}{4}$ of that at B. Its numerical value is $\frac{2}{4} \times 100 = 50$ pounds. The force, or pressure, at C is the sum of those at B and D, and its numerical value is $100 + 50 = 150$ pounds.

By increasing the length of the longer lever arm of the shaft to 8 inches, as in Fig. 2, the pressure at D is decreased in the same proportion. It becomes equal to $\frac{2}{8} \times 100 = 25$ pounds; and the pressure at C is decreased by the same number of pounds as that at D. The numerical value of the pressure at C, Fig. 2, is $100 + 25 = 125$ pounds.

In Fig. 3 the longer lever arm is 40 inches in length. It is ten times as long as in Fig. 1. The pressure at the end of the longer arm is thus reduced to $\frac{2}{40} \times 100 = 5$ pounds; and the pressure at C is reduced to $100 + 5 = 105$ pounds.

The longer lever arm of 40 inches in Fig. 3 gives a pressure at the fulcrum C that is 30 per cent. less than that at the corresponding point in Fig. 1. Or, expressed in reverse order, the pressure at C in Fig. 1 for the short shaft, is more than 42 per cent. greater than that at C in Fig. 3 for the longest shaft. The pressure at D near the end of the shaft is ten times as great for the short shaft as for the long one.

The side pressures on the bearings of the pinion-gear shaft are affected in exactly the manner just given by changing the distance between the bearings which support the shaft when both of the two bearings are on the same side of the pinion. It is quite common, although not the universal practice, to place both bearings in front of the pinion bevel gear which drives the bevel gear on the rear axle, or on the differential case.

Lack of Alignment Worse Than Wear on Bearings

Even if the wear on the bearings of the short pinion shaft is exactly the same in amount as on those of a longer shaft with a greater distance between bearings, the short shaft is thrown out of proper alignment to a greater extent than the long one. This throwing out of alignment destroys proper meshing, or engagement, between the pinion and its mating bevel gear. The teeth of the pinion and gear are thus caused to bear against each other at and near only one end. Noisy running and rapid wear of the gear teeth are the result. It is extremely important that the bevel gears be kept in proper position relative to each other. Displacement from these proper positions has a far greater action to injure and destroy them than in the case of plain spur gears designed to run on shafts parallel to each other.

There are therefore two strong reasons against using a very short shaft for carrying the pinion gear that drives the large bevel gear mounted on the differential of the rear axle. These are, as just stated, the high pressure and consequent great wear that are brought on the bearings on account of the necessity of placing them near together on the short shaft, and the greater amount of displacement of the pinion gear from its proper position to mesh with its mate allowed by the shorter shaft, even when the amount of wear at the bearings is the same for both the short and the long shafts.

It certainly is well worth while to adopt a design which gives a low pressure on the bearings, provided such a design does not bring in other features that are more objectionable than heavy bearing pressures and improper meshing of the bevel gears.

Small Angle Reduces Rotary Irregularity

What may at first seem a very serious objection to the use of only one universal joint in the transmission system, as compared with the use of two such joints, is the uneven, or jerky, action of a single joint in transmitting rotation when the two shafts which it connects are not in line with each other, which is the usual condition. But the considerable length of propeller shaft between the rear axle and a universal joint located well forward toward the motor makes it possible to keep the angle between the propeller shaft and the one which drives it comparatively small, thus reducing to a minimum the irregularity of relative rotation of the two shafts thus connected. Aside from this it is desirable to keep the angle between the two shafts small in order to keep down wear in the joint itself. In fact, in well designed cars with only one universal joint, wear in the joint generally needs more consideration than the jerky motion of the driven shaft due to the action of the universal joint. This wear, as well as the irregularity of rotation, is greater whan the angle between the shafts is large than when it is small.

The long propeller shaft, if of as small a diameter as is allowable with high-grade steel, is elastic enough torsionally to yield by twisting slightly when the rotative effort acting upon it is momentarily increased by the irregular rotative action of the universal joint. This giving, or elastic yielding, of the propeller shaft prevents injuriously heavy stresses in the gears at the rear axle, as well as in all of the other parts of the transmission mechanism.

If the crankshaft of the motor rotates at a uniform speed, the propeller-shaft is driven at a higher speed of rotation than that of the crankshaft twice during each revolution of the propeller shaft, on account of the uneven action of the universal joint. It is during the periods in which the rotative speed of the propeller is increasing relative to that of the crankshaft that the strain comes on the transmission mechanism. The speed of the propeller shaft also drops behind that of the crankshaft twice during each revolution in order to compensate for the more rapid temporary speed. In the statements of this paragraph it is assumed for simplicity that the direct connection is in use between the crankshaft and propeller shaft, so that the average speed of rotation of the two shafts are the same.

Smallest Angle With Transmission on Rear Axle

When the change-speed gears are located just forward of the rear axle, the universal joint can be placed farther forward than when the change-speed gears are placed just in the rear of the motor and clutch. The universal joint can in fact be made a part of the clutch when the change-speed gears are just forward of the rear axle. The latter arrangement is therefore the one by which the angle at the universal coupling between the motor and propeller shaft is the smallest that can be obtained by any arrangement using only one universal coupling. In this arrangement the shafts in the change-gear case are parallel to the propeller shaft and are therefore inclined upward toward the front of the car.

If the propeller shaft makes direct connection with the pinion-gear shaft for high speed of car travel, as is the more usual practice, then the center line, or axis, of the propeller shaft must intersect the axis of the rear axle when the usual conical bevel gears are used at the rear axle part of the transmission system. The length of the inclined propeller shaft is then, in effect so far as its inclination is concerned, from the clutch to the axis of the rear axle. This extreme length of course gives the minimum inclination to the propeller shaft for given relative positions of the motor and rear axle.

The pinion-gear shaft can be made long enough, when the change-speed gears are just forward of the rear axle, to allow a distance between the bearings of the pinion shaft sufficient to keep the bearing pressures comparatively low, unless the form of change-speed gears is such that the gear case is very short, as may be the case with selective gears.

It may at first seem that a smaller diameter of propeller shaft can be used when the change-speed gears are at the rear axle than when they are near the motor. This would be true if the clutch would never grip hard so as to suddenly check the speed of the motor when the clutch is put into engagement to start the car. If the gears are set at high speed and the clutch is engaged while the motor is running fast, sudden seizure of the clutch will cause the road wheels to spin. The torque and stress brought upon the propeller shaft by such an action are the same as if the change-speed gears were near the motor and set at slow speed. A corresponding action occurs when the motor is allowed to stop while the car is descending a hill and the clutch is then engaged to start the motor; the limit of the stress on the propeller shaft is then determined by the skidding of the wheels.

One Disadvantage of Rear Location

A very serious disadvantage of the change-speed gears at the rear axle is the increased dead weight on the axle and wheels. This increase of dead weight varies from probably 50 per cent. to 100 per cent. or more of the dead weight on the rear wheels when the change-speed gears and their casing are carried on the frame of the chassis. Dead weight on the axle and wheels is far more injurious to the tires than the same amount of weight carried on springs. It is especially hard on the tires when both rear wheels strike an obstacle, or a gulley, at the same instant. Street crossings and railway tracks above the level of the road are not unusual, and gulleys are often found in country roads. It is a fixed rule in the older forms of transportation devices to keep dead weight off the axles as far as possible.

When the change-speed gears are located just in the rear of the motor, the distance between the universal joint and the rear axle is necessarily less than when the change-speed gears are at the rear axle. The angle at the universal joint is therefore grater when the change gears are located near the motor, which is a disadvantage. With planetary gears or a short gear case containing sliding gears of the selective type, the distance from the universal joint to the rear axle is not much less than when the change-speed gears are at the rear axle, however.

As a total, the advantages seem to lie in favor of the designs of transmission mechanisms in which short change-speed gears are located in the immediate rear of the motor.

It may also be noted that a motor with its cylinders cast en bloc and having a two-bearing crankshaft support is favorable to increasing the distance between the universal joint and the rear axle, and thus to reducing the angle at the universal joint, since such a motor is shorter than one with individual cylinders.

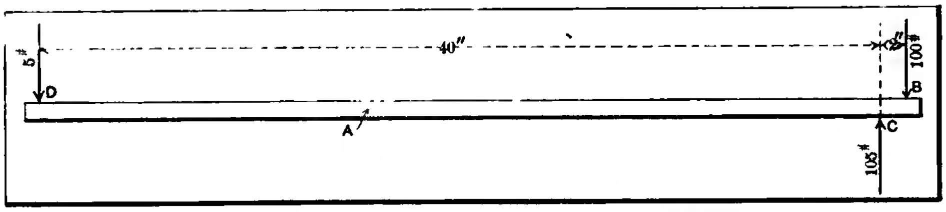

Fig. 3—Longer lever arm arrangement which reduces pressure at a given point

Minneapolis Draws Crowds From Northwest

MINNEAPOLIS, MINN., Feb. 21—A bigger and better automobile show describes Minneapolis' third annual show, which began last Saturday at the National Guard Armory and will continue a week. Visitors from Minnesota, Wisconsin, North and South Dakota, Montana and Western Canada, have been in attendance. There are a greater number of exhibits than have ever been shown before, 110 makes of cars being displayed, which is 50 more than last year. There are upwards of 20 exhibits of automobiles at the show that have never been sold in this territory before this year.

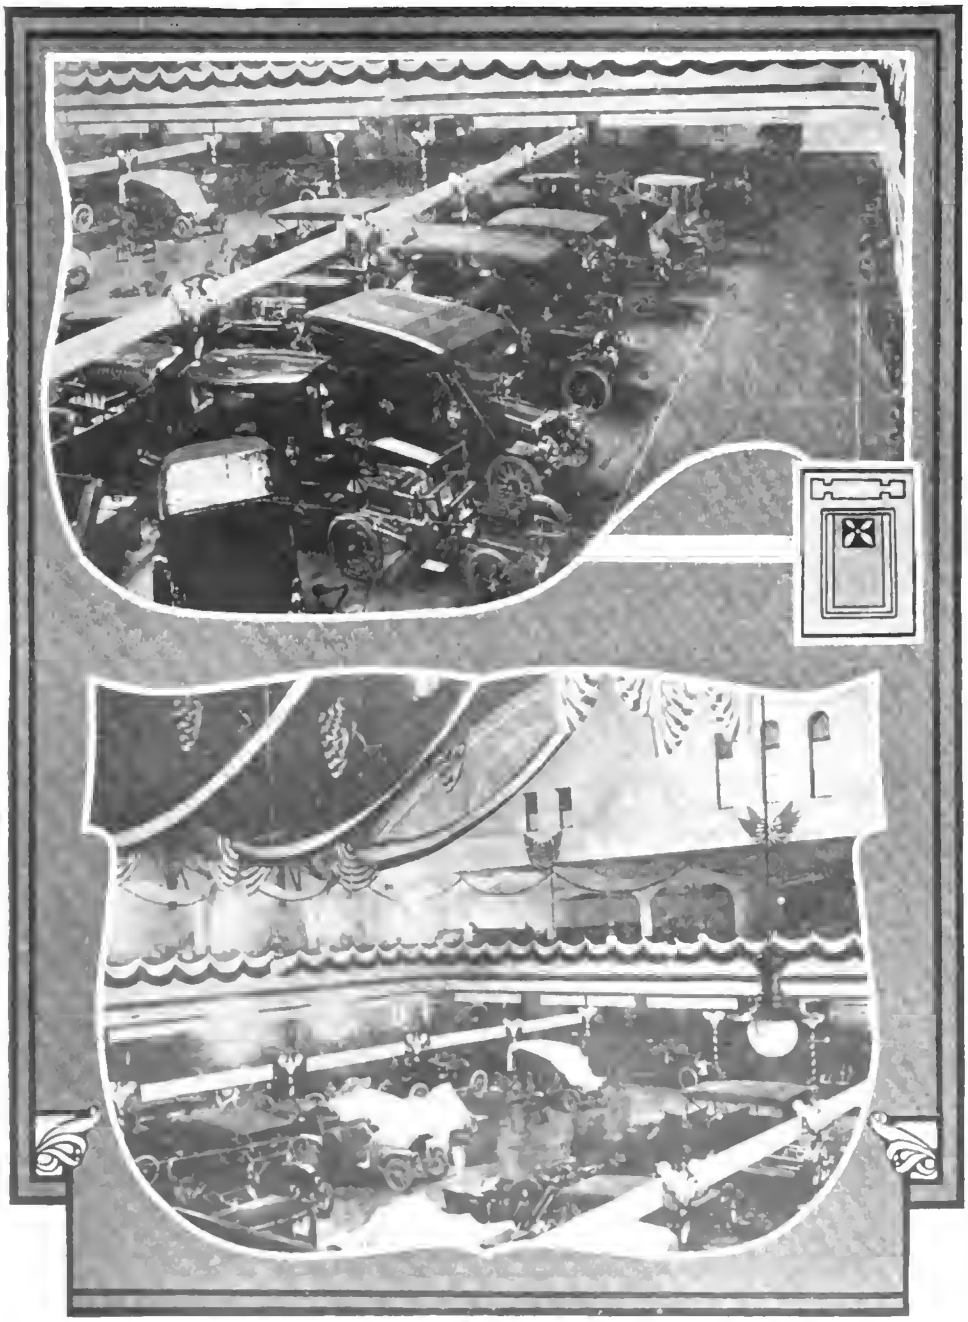
The lighting and decorative features are unusually elaborate. The main floor of the armory is ablaze with lights grouped in immense clusters on twelve posts and thousands of incandescent electric lights stud the ceiling and illumine every booth. Music is furnished afternoon and evening by the First Regiment band.

The liberal display of electric automobiles, commercial trucks and the overflow of pleasure cars are shown in the basement. Judging from the unusually large number of exhibitors, the management will be compelled to secure larger quarters for their show next year.

Walter R. Wilmot is manager of the show and the officers of the Minneapolis Automobile Association are Harry E. Pence of the Pence Auto Company, president; H. E. Wilcox of the H. E. Wilcox Motor Car Company, vice-president; F. E. Murphy, secretary and treasurer. Horace Lowry is president of the Minneapolis Automobile Club, and Reuben Warner of St. Paul is president of the State association.

The exhibitors and exhibits follow:

The Pence Auto Company has a unique exhibit of Buick, Oldsmobile and Oakland cars. It is also showing a collection of Buick trophies valued at $46,000. Louis Chevrolet, of the Buick team, accompanied the trophies to Minneapolis and is in attendance at the show. The Mich-Stair Company shows Overland and Knox 1910 models. The Knox four-passenger runabout and the Knox model R, with torpedo body, both fully equipped, are features of this display. The Knox tonneauette and the Knox six-cylinder, seven-passenger touring car are also being shown.



TOP—MINNEAPOLIS SHOW SEEN FROM THE GALLERY; WINTON IS PROMINENT
BOTTOM—LOFTY ROOF OF THE ARMORY, DRAPED WITH BUNTING AND FLAGS

The Columbus Buggy Company is exhibiting the Mora car, the Columbus electric in its various models and the Firestone Columbus touring car. The Northwestern Auto Company shows a Ford chassis, the engine of which is run by an electric motor. The Goosman & Johnson E-M-F. Company shows the E-M-F 30-horsepower roadster and the five-passenger E-M-F touring car. The Flanders "20" and a Speedwell touring car are also displayed.

The Deere & Webber Company shows a complete exhibit of the Velie "30," model D, 40-horsepower, model E roadster and model F top tonneau. The Northwestern Stearns Company is exhibiting a line of 1910 Stearns touring and roadster cars. The H. E. Wilcox Car Company show the 1910 models of the Wilcox pleasure cars. The Ramaley Auto Company, St. Paul, shows the 1910 models of the National cars.

The Great Northern Implement Company shows for the first time in Minneapolis the "Ohio" in its various models. The Whiting roadster, four-cylinder, 20-horsepower, with full equipment, is also on this stand. An attractive display, including the model 30 Limousine, is that of the Northwestern Cadillac Company. This concern's exhibit also includes a polished chassis with exposed engine. The Luverne Auto Company, Luverne, Minn., exhibits the Luverne "40," its leading model.

and a chassis. P. J. Downs & Company are exhibiting the new 1910 Rambler in three models.

The Tri-State Automobile Company, which recently took on the agency of the Paige-Detroit, has on display one or two models of this car and also the Inter-State four-cylinder car in three styles—baby tonneau, roadster and touring car. The Regal "30" 5-passenger touring car and also a chassis of the same make; the Pennsylvania model C, a six-cylinder chassis; model D, with toy tonneau are the cars which the Haynes Automobile Company has on view. In this booth also is shown the Pennsylvania sectional motor.

The Royal Auto Company has two booths, in which are exhibited the Royal Tourist four-cylinder, both in the limousine and touring car bodies, with chassis; the Glide four-cylinder, seven-passenger with the new 40-inch wheels, and also a chassis of this car with the mechanism of the engine exposed. Two booths are occupied by the Fawkes Auto Company, in which are exhibited three models of the Marmon with full equipment; a Matheson six-cylinder touring car and chassis; a Reo four-cylinder car and an American.

A striking exhibit has been put on by the Maxwell-Briscoe Company. The Hathaway-Stimpson Company has displays of the Hupmobile and the Detroit electric. Mr. Stimpson has made special arrangements to have shipped to have on view a four-passenger Detroit electric brougham done in pearl gray with pure white stripes and gray French whipcord upholstering. The W. H. McIntyre Company has on display model M-2, four-cylinder roadster; model M-4 four-cylinder touring car and a model A-1 runabout. Models of the Halladay are shown by the Heaney Automobile Company, the exhibit being one of the most complete in the entire show. In addition to nine Halladay models, a polished chassis and engine are displayed.

The Barclay Auto Company is displaying the Chalmers 30-horsepower touring car, also the Hudson in two models, the roadster and touring car. The Franklin and Baker electrics are featured by the Robertson Motor Company.

The MacArthur Zollars Company has in its array of cars new 1910 models of the Everett "30," the Corbin, the Anhut Six, the American Simplex, the Black-Crow and the Babcock electric. The Moore Carving Machine Company is showing four or five models of the Elmore, and another feature of this booth is the fine display of Woods electrics. Moore Brothers, Wimbledon, N. D., are showing three cars of their own make. The Pierce-Racine Company shows two models of the Pierce-Racine Model K, a close-coupled toy tonneau and a Pierce-Racine touring car. T. C. Peebles recently took the local agency.

A special exhibit of Peerless and Pope-Hartford cars shipped directly to Minneapolis from the Chicago show has been put on view by the T. M. Anderson Company. The Northland Motor Car Company is showing the Stoddard-Dayton model K, the toy tonneau F-A-L-Car and the Courier roadster.

Joy Brothers have on exhibition in various styles the Packard touring car and one of the new Packard commercial trucks. The Winton Six touring car, accompanied by a chassis and a toy tonneau, are in the booth reserved by the Winton Motor Carriage Company. The Electric Carriage & Battery Company is exhibiting several models of Rauch & Lang electrics. Handsome coupés, broughams and victorias are among those on view. A complete line of the renamed Maytag cars has been put on by the Maytag-Mason Company.

The White garage has three models of White cars on exhibition; two are steamers and one a White gasoline car. The Warren-Detroit Company is exhibiting the Warren-Detroit car in the booth with the Ranger Auto Company. The car is one of the recent makes to invade the Northwest. The Kemp Brothers Automobile Company is showing a complete line of Brush cars fresh from the factory. In its booth the Ranger Auto Company is showing the Auburn touring car.

A. A. A. RACING BOARD PUTS FORTH ITS BEST EFFORT

TRACK, hillclimbing, and long-distance racing rules, as issued by Chairman Butler of the A. A. A., to govern events during the year 1910 differ from the rules which previously obtained. This year stock cars are defined by a percentage system, whereas last year 25 automobiles of a given model were all that had to be designed and constructed in order to bring the model within the classification designated as "stock cars." In the new percentage system, a company which has an annual output of a given model of 50 cars or less, the Commitee must see 25 automobiles, but if the output is 10,000 the minimum number, from the Committee point of view, will have to be 450.

The piston displacement classification remains as before, with the exception that 100 pounds have been dropped from the weight of each class. The options permitted for the stripped stock chassis is but slightly altered, it being provided that bonnet straps must be added, and that part of the dash enclosing the rear of the bonnet, together with all its customary equipment, muts be retained. Drivers will have to obtain a certificate, and be registered with the Contest Board.

Amateurs are defined as those who are not actively engaged, either in the automobile industry directly, or in the accessory business. The new rules seem to be most carefully drawn, and evidently reflect the experience of the last year, and Chairman Butler seems to have taken into account the points of demerit, to the extent that they are eliminated. The following is a brief résumé of the principal amendments of the 1910 contest rules as adopted by the Contest Board, and approved by the Board of Directors of the American Automobile Association, and the Manufacturers' Contest Association at Chicago, February 10, 1910:

Stock Car—"A motor car, the complete description of which, upon the official blank provided for the purpose, has been filed with the main office of the Technical Committee of the Contest Board at least 30 days prior to the date of the contest entered, the quantity production of which bears to the total yearly production of its manufacturer the ratio set forth in the following table, and which is on sale through the regular selling representatives of the manufacturer."

Official blanks for stock car description may he obtained from the chairman of the Contest Board, 437 Fifth avenue, New York City.

Computation in connection wtih the following table shall be based upon a period of time from July 1 to June 30 the following year.

In computing the annual output of a manufacturer, no account shall be taken of his production of taxicabs, delivery wagons or other vehicles designed for commercial use.

At the discretion of the Contest Board any competitor may be required to file a bond of $5,000 that the entry made by him is a bona fide stock car within the meaning of this definition:

Total Output.	Percentage.		Number of Same Model.
10,000 or more	4.5%	equaling	450 minimum
8,000 to 9,999	5.0%	equaling	400 minimum
6,000 to 7,999	6.0%	equaling	360 minimum
4,000 to 5,999	7.0%	equaling	280 minimum
2,000 to 3,999	8.0%	equaling	160 minimum
1,000 to 1,999	9.0%	equaling	90 minimum
500 to 999	10.0%	equaling	50 minimum
250 to 499	16.0%	equaling	40 minimum
100 to 249	30.0%	equaling	30 minimum
50 to 99	50.0%	equaling	25 minimum

Explanation—Percentages are calculated on actual total output. For example: If the total annual output of a manufacturer is 2,500 cars, at least 8 per cent. of said output, or 200 cars, must he of the same model in order to constitute such model a stock car under this definition. The required percentage of output shall in every case be in accordance with the above table and in no event shall it be fewer than 25 cars.

Rule 69. Motor Exhaust—The exhaust must be conducted outside of the bonnet and so directed as not to raise dust.

Rule 70. Loss of Bonnet—The bonnet must be carried throughout a contest. If the bonnet becomes detached or lost from a car, the driver shall be required to bring his car to a stop in the shortest possible distance consistent with safety and remain at a standstill until the bonnet has been recovered and replaced.

In a road race he shall not pass the judge's stand until the bonnet has been so recovered and replaced.

In contests on tracks and speedways, a bonnet lost in one lap may he recovered in the next succeeding lap.

Bona Fide Status of Stock Car—It is the intention of the rules relating to stock car and stock chassis competitions that such competitions shall be restricted to those cars identical in specification, material and design with the manufacturer's product which is manufactured in quantity and is offered for sale and sold in a bona fide manner to the public through the regular selling agencies of the manufacturer.

Evasion of Stock Car Definition—In the event of evasion on the part of entrants of the spirit of the stock car or stock chassis definition concerning points not definitely stated in these rules, the Contest Board shall have full power to render such decision as it may deem for the welfare of the sport and industry.

Technical Committee—In any case where it may be necessary to establish the status of any car alleged to be a stock car under the definition contained in these rules, the Technical Committee of the Contest Board shall have the right to visit the factory of the manufacturer of such car, who shall be required to submit to the committee such evidence as it may require to verify the allegation on which the stock status of the car is based.

The Technical Committee shall also have power to take possession of any competing car at the finish of its competition in any contest and make such examination thereof as may be necessary to establish its stock status.

CLASSIFICATIONS

Class A. Price Classification—The numbering of the divisions in this class has been reversed, division 1A being made the lowest priced cars and seven divisions are provided in this class, instead of six as heretofore:

Class A—Open to any gasoline motor car other than motor cars with solid tires, wheels 36 inches in diameter and over, which complies with the definition stock car, this class to be run in the following divisions:

Division 1A	$ 800 and under
Division 2A	801 to $1,200
Division 3A	1,201 to 1,600
Division 4A	1,601 to 2,000
Division 5A	2,001 to 3,000
Division 6A	3,001 to 4,000
Division 7A	4,000 and over

Extra or optional equipment, listed in the manufacturer's catalog as such, used upon a car competing under price classification, must have its list price added to the list price of the car, and this total price shall determine the classification of the car. No extra equipment shall be permitted other than that listed as such in the manufacturer's catalog.

No car shall compete in any class above that to which its price entitles it.

Class B. Piston Displacement and Minimum Weight Stock Cars—The numbering of the divisions in this class has been reversed. division 1B being made the smallest piston displacement, 160 cubic inches and under, and a sixth division has been added for the larger cars. It should also be noted that in this piston displacement class it is intended that cars should compete at their normal minimum chassis weights, the adding or attaching of any dead weight to the car as ballast to enable it to compete in any other division than that to which its normal chassis weights entitle it, being prohibited.

To meet this prohibition against ballast, the minimum chassis weights have been reduced 100 pounds in each of the six divisions.

Class B—Open to any chassis of a gasoline car which is in accordance with the definition of a stock chassis; to be governed by the following table of piston displacement and minimum chassis weights:

Division.	Piston displacement in cubic inches.	Minimum weight in pounds
1B	160 and under	1,100
2B	161 to 230	1,400
3B	231 to 300	1,700
4B	301 to 450	2,000
5B	451 to 600	2,300
6B	601 to 750	2,500

No car shall compete in any class above that to which its weight entitles it.

No dead weight of any description shall be added to a car or attached thereto in any manner as ballast.

Class C. Piston Displacement Without Minimum Weight Restrictions or Stock Car Qualifications—This class has been added to afford an opportunity for competition between motors of approximately equal size, six divisions being provided according to piston displacement but without stock car qualification or minimum weight restrictions.

This class might be considered the experimental or development class.

Class C—Open to any gasoline car or chassis made by a factory which has during the 12 months prior to the date of contest produced at least 50 motor cars, not necessarily of the same model. Eligible for entry under the piston displacement limitations of class B, but without minimum weight restrictions.

Division.	Piston displacement in cubic inches.
1C	160 and under
2C	161 to 230
3C	231 to 300
4C	301 to 450
5C	451 to 600
6C	601 to 750

No car shall compete in any class above that to which its piston displacement entitles it.

The other classes are amended as follows:

Class D—Open to any gasoline car which complies with the definition of a motor car without restriction as to piston displacement. weight, price or quantity produced. There may not be more than two events under class D upon a day's program without special permission of the Contest Board.

Class E—Special events other than those above specified held in connection with any motor car meet or contest, and approved by the Contest Board of which there may not be more than three upon a day's program without special permission of the Contest Board.

Class F—Open to gasoline stock cars of the high-wheeled, solid-tired buggy type, diameter of wheels 36 inches or over. Entries subject to price limitations of class A. There may not be more than two events under class F upon a day's program without special permission of the Contest Board.

Class G—Open to electric stock cars only. Subject to the price limitations of class A.

Class H—Open to commercial cars, cabs and trucks. Division limitations to be obtained from the Contest Board.

Match Races—Matches may be held as contests of any kind covered by any of these rules and may be run under any of the classes or divisions.

GENERAL AND SPECIAL RULES

The contest rules have been rearranged and classified into: (a) General rules applicable to all contests, and (b) special rules for each of the various forms of contests as follows: Special rules for road races. Special rules for track races. Special rules for long distance track and 24-hour track races. Special rules for hill-climbs. Special rules for reliability contests and tours.

GENERAL RULES

First—Provisions have been made for the appointment by the Contest Board of the referee for every contest, from a selected list of men of undoubted standing, familiarity with and ability to administer the contest rules, located in every locality where contests will be held and known to the promoting clubs and associations in those localities.

Second—To the further end of establishing and maintaining the strict compliance of all entrants with the stock car requirements of the rules, a technical committee is provided, of which the associate member of the A. A. A. Technical Committee in the district where the contest is held, shall be chairman, together with such other technical members as the promoter may appoint, to technically inspect all cars offered for competition and to prevent the entrance of other than bona fide stock cars.

Third—The third element to complete the organization of the Contest Board is found in the official representative of the board previously provided for, who will be in attendance at every contest to co-operate with the referee and the Technical Committee in the strict enforcement of all the Contest Board rules.

Entries—The promoter is prohibited, under pain of disqualification, from advertising the proposed competition of any entrant in a contest until his entry has been actually made. The promoter is also required to secure a signed entry blank and entry fee from a proposed entrant, in order to bring such entrant within the jurisdiction of the Contest Board's discipline in case of his failure to appear.

Supplementary Regulations—In order that the governmental functions and supervision of the Contest Board may extend to every form of contest, a promoter desiring to make regulations for some particular form of contest not included in the published rules of the Contest Board, may do so upon submitting such supplementary regulations to and receiving the approval of the Contest Board.

Certified Trials—To put the stamp of authenticity upon any special form of road trial or test of an individual motor car or accessory, the maker, owner, agent or dealer may secure from the Contest Board an official sanction for such trial, which will be carried on under the supervision of a representative of the Contest Board under the general rules and the special rules of the board in such case provided.

Advertising—To prevent the holding of contests which could not, in any way, redound to the benefit of the sport and idustry, the following rule has been adopted.

"Any owner, manufacturer, dealer, agent or driver taking part in or directly connected with any contest otherwise than under these rules, and obtaining extensive advertising therefrom, shall be deemed to be guilty of a breach of these rules."

Records—To prevent the indiscriminate advertising and improper comparison or performances or alleged records, all claims for records must be made to the Contest Board within 10 days of their accomplishment and no record shall be advertised until accepted and allowed by the Contest Board. The board may reject any claim which in its opinion would not promote the best interests of the sport.

No claim for a record at a distance under 1 mile and up to 5 miles will be allowed unless taken with a recording automatic timing device and the actual recorded evidence submitted.

Provision is made for a register of records to be kept by the Contest Board.

Racing Drivers' Register—All racing drivers are required to register with the Contest Board and receive a registration card, such registration expiring on December 31 of each year. A detailed record of each driver's participation in contests throughout the year will be kept. Drivers are required to exhibit their registration cards to the referee on demand at any meeting.

An unregistered driver may not compete in any sanctioned event.

Amateur Definition—The definition of an amateur is amended by adding an additional restriction so that "no one who is actively engaged in the motor car or accessory industry" may compete as an amateur.

Amateur Drivers' Register—For the protection of the amateur driver and to afford bona fide amateur competition, an amateur drivers' register has been established, requiring annual registration with the issuance of a registration card by the Contest Board.

An unregistered amateur may not compete in sanctioned events.

Amateur Entries—An amateur shall neither enter for nor drive in any contest a car which is the property of any person or corporation actively engaged in the motor car or accessory industry.

Powers of Referee—For the safety of all concerned, the referee's powers have been broadened, as follows:

He shall prohibit any driver or mechanic from entering or continuing in any contest who, in his opinion, is physically unfit.

He shall have the right to stop a race before its scheduled termination if emergency demand such action, and in such a case no award shall be made.

He may order the postponement of an event for any reason which, in his judgment, after consultation with the promoter and representative of the Contest Board, may be valid.

At his request, a driver or mechanic must furnish a physician's certificate as to his physical and optical fitness to enter a race, or may be required to submit to a test to determine such fitness.

The following provision has also been added to the duties of the referee:

"The referee may disqualify any driver, mechanic, entrant or entrant's representative who shows discourtesy toward any official."

Delivery of Prizes—In the event of a protest, or an appeal to the Contest Board from the decision of the referee, no prizes shall be delivered until an official decision is rendered.

Promoter's Liability—Promoters are required to use every precaution in the proper preparation of the track or course and the proper safeguarding of same during practice or the running of a contest, and shall be held responsible for any accidents resulting from their negligence in these matters.

Unadulterated Fuel Supply—Stringent regulations are provided for the testing of contestant's gasoline and to insure the use of a standard and unadulterated fuel supply. Disqualification of the owner, entrant, driver and car, or all of them, is the penalty.

SPECIAL RULES FOR ROAD RACES

The protection of the public and of the contestants being the paramount consideration in the running of a road race, the following rules have been adopted:

Permits to Use Road—Before official sanction will be granted for a road race, hill-climb or speed trial, or any other competition on the public highway, a promoter shall first obtain the properly authorized permission of any and all local authorities for the use of such highway and shall file the original or a certified copy of such permission with the Contest Board.

MILESTONES FOR THE AUTOMOBILIST

Feb. 24-Mar. 8...Toronto, St. Lawrence Arena, Canadian Automobile Show, Ontario Motor League. E. M. Wilcox, Mgr.

Feb. 28-Mar. 5...Omaha, Neb., Auditorium, Automobile Show, Omaha and Council Bluffs Automobile Dealers.

Feb. 28-Mar. 5...Kansas City, Convention Hall, Fourth Annual Automobile Show, Automobile Dealers' Ass'n.

Mar. 5-12.........Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.

Mar. 5-12.........Cleveland, Central Armory, Cleveland Automobile Club, Eighth Annual Show.

Mar. 5-12.........Des Moines, Ia., Coliseum, First Annual Automobile Show, Des Moines Automobile Dealers' Ass'n.

Mar. 7-12.........Albany, N. Y., Armory, Automobile Show.

Mar. 15-19........Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

Mar. 15-19........Bridgeport, Conn., Automobile and Aeronautic Show, Bridgeport Automobile Dealers' Ass'n.

Mar. 17-19........Louisville, Ky., Automobile Show, Louisville Automobile Dealers' Association, in the Louisville Armory. Hubert Levy, Secretary.

Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo Launch Club. D. H. Lewis, Mgr., 760 Main St.

Mar. 21-28........Denver, Col., Convention Hall, Denver Motor Club's Annual Automobile Show.

Mar. 26-Apr. 2....Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

Mar. 26-Apr. 2...Montreal Automobile and Motor Boat Show, Official Motor and Sportsmen's Show Committee of the Automobile and Aero Club of Canada, in the Coliseum. E. M. Wilcox, Manager, 123 Bay St., Toronto.

Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

RACES, HILL-CLIMBS, ETC.

Feb. 19-20.......Los Angeles, Ascot Park Track, Track Races of Los Angeles Motor Racing Association.

Feb. 22..........Oakland, Cal., Hill Climb, Auto Trades Association of Oakland and Alameda County, Cal.

Mar. 5...........New York to Boston, Voting Trophy Contest, T. F. Moore, Manager, 91 West 103d St., New York City.

Mar. 19..........Altadena, Cal., Hill Climb, Licensed Motor Car Dealers' Association, Los Angeles, Cal.

FOREIGN SHOWS AND RACES

Feb. 18-26........Manchester, England, Automobile Show.

Feb. 20-23........Swedish Automobile Races and Trials.

Mar. 19-Apr. 3...Berlin Automobile Show.

Mar. 22..........Monte Carlo Elegance Competition.

Mar. 27-Apr. 4...Prague, Austria, Hungary, Automobile Show.

Mar. 28..........Brooklands, England, Easter Meeting.

Mar. 31-Apr. 8...French Spring Wheel Competition.

Apr. 2-24........Turin, Italy, Automobile Show.

Apr. 27-28........Brooklands, England, Two-Day Meeting.

May 1-Oct. 1.....Vienna, Austria,-Hungary, Automobile and Aviation Exposition.

May 28-June 9...St. Petersburg, Russia, Automobile Exhibition.

June 2-8.........Prince Henry (German) Touring Competition.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

Autoing in foreign lands presents the advantage to one of becoming ultimately acquainted with the byways, the natives in their simple aspect, and the vagaries of the countryside. It is a pleasureable pastime, and as remote from the boredom of conventional forms of doing other lands as anything can be.

The anticipation of pleasure in this form is not in the absence of other and equally attention-drawing phases. If reliance is placed upon "cars to hire" in the industrial haunts of the many lands, it demands self-restraint almost in excess, to keep down the qualms which foreshadow remorse, and, in the long run, the cost is likely to be overmuch.

If the automobile is to be taken along, it may, or may not, be necessary to include a chauffeur; the skill and inclination of the owner will settle this important phase. At all events, the automobile must be properly boxed for transportation, and this essential is so frequently left to a carpenter of no enterprise, that the end is plainly not pleasant to contemplate. To be sure that an automobile will survive a voyage, is to box it properly, and a man of some knowledge and experience should be entrusted with the undertaking.

Insurance must be taken out, with permission to go abroad, and this is not a detail which can be disposed of offhand. Insurance underwriters are disinclined to act in haste.

Custom requirements differ in the several countries, and tariff regulations must be observed on the frontier of every principality. In the absence of knowledge of the laws, customs, and inclination of the "natives," it is a task of moment; the score will mount up, and the pleasure which should attend a tour, will be dimmed by sad experiences. As a rule, courtesy and firmness will make headway against the bickerings of an obdurate official, but firmness is only to be fortified when knowledge is a companion.

Autoists, after they run an automobile through its second season, perhaps are, in quite a number of instances, conscious of a something which falls short of due explanation. The original sweet-running qualities lapse, and scrubbing the carbon from off the combustion chamber surfaces fails to effect a cure. After a few trips to the repair shop, the discovery is made that it is the cooling system which must be corrected, and how to rehabilitate the same is a problem. A little investigation in proper channels is enough to disclose a condition of incrustation, and, within the confines of a radiator the hard crust persists despite treatment. There is no room for a scraper, and there seems to be no other way to remove the coating. This form of trouble is least in radiators which are of sufficient area to keep the water well below the boiling point, and autoists, if they will not run on a retarded spark, will lengthen the useful life of the cooling system.

When an automobile is to be left unused, by the curb, to stop the motor is advisable, not only because it is economical of fuel, but in order to prevent overheating of the cooling water.

There should be some way of aiding autoists, or those who desire to purchase, which would enable them to reach conclusions which would be in accord with the facts and in harmony with their respective situations. As it is, they are prone to take too much time discussing "selling points" and very little time consulting their own needs. The real situation is that the needs are first and the supply must satisfy the demand. If a system of "points" could be devised on a basis which would serve the needs of the mechanically disinclined, it would be a relatively easy matter for the budding autoist to go into a show and examine such of the several hundred models as would promise to come within the requirements.

There are two angles to take, however, and the point system would have to be so contrived as to satisfy the situation bearing this matter in mind. The man who has a limited amount of money wants an automobile with a limit to its first cost and he naturally will be interested in the cost of maintenance. Since the speed of a car will largely influence the cost of maintenance (independent of the quality of the material and workmanship to a considerable extent) the system to use is one which will allow for speed as it induces depreciation, and at the same time reflect the presence of material as it is good, or otherwise, and appropriateness of design from the point of view of the prospective user considering his needs. The average intending purchaser is very prone to think that a design is not very good, if, in his judgment, it falls short of his own particular needs, and in thus hastily reaching a conclusion, he fails to remember that some other possible user will find what he may want in the very automobile so hastily judged.

LOCAL SHOWS FLOURISH THE COUNTRY OVER

CINCINNATI SHOW REPORTS MANY SALES

Cincinnati, Feb. 27—Music Hall closed its doors at 11 o'clock last night on the most successful automobile show ever held in this vicinity, after a jollification in which Anna Held and her company played a prominent part. There can be no doubt that henceforth the automobile shows under the auspices of the Cincinnati Automobile Club will be held annually.

It was the most complete exhibition of cars the residents of the city and its neighborhood have ever seen, and the decorations enhanced the effect. An army of out-of-town salesmen was here, and all found time to compliment the management on its work. As most of them had made the round of New York, Buffalo and Chicago, their judgment should be valuable.

It would be hard to give the exact number of sales made during the week, but the records would speak well for everybody. The Jungclas Automobile Company, which is the local agent for the Mitchell, showed the signatures of 36 actual buyers, 16 of them credited to subagencies. The Enger Company, a new manufacturing firm of this city, sold 50 cars in one day to subagencies, besides making a number of individual sales. The Cadillac Company reports that it sold 16 cars during the week. The Cino and Ohio, other new local products, also disposed of a large number. Powel Crosley, of the Haberer Company, which makes the Cino, booked an agency in Indianapolis which has contracted for 25 cars. The Cino will be exhibited at the Kansas City, Mo., show, and the Ohio is on exhibition at Cleveland and Boston.

MILWAUKEE'S SHOW TAXED TO CAPACITY

Milwaukee, Wis., Feb. 28—Milwaukee has again outdone her former achievements in the matter of an automobile show which opened there on February 22 under the auspices of the Milwaukee Automobile Club, and, according to consensus of opinion, this exhibition is said to have been a fine and most varied exposition of the automobile industries.

The show practically opened in the afternoon, when General Manager Clarke S. Drake and the show committee, consisting of M. C. Moore, Christ Schlotka, L. A. Dearholt, O. F. Fishedick, Dr. Louis Fuldner, gave a reception to members of the Milwaukee Automobile Club and a number of guests. This function took the form of a "private view" and was followed by a luncheon.

This exhibition covered about 40,000 square feet of floor space, and the auditorium in which the show was held was beautifully decorated. All of the sixty-two boxes encircling the arena was occupied by Milwaukee and Wisconsin society people, while the 4,000 seats in parquet and balcony were free to visitors at all times.

In the matter of exhibitions, it is said that applications for space far exceeded the capacity of the auditorium and every nook and corner was utilized by the exhibitors.

PORTLAND MADE GOOD WITH 1910 SHOW

Portland, Me., Feb. 28—The show ended Saturday to the entire satisfaction of the management, and will be reserved in the minds of local automobile enthusiasts for a considerable time to come as one of the real situations, portraying a condition of stability, and the healthy growth of the automobile industry. The auditorium in which the show was held was appropriately spruced up for the occasion, and it was common accord among the visitors that Frederick M. Prescott has reached a point in his managerial career where experience and acumen is scarcely to be enlarged upon. The attendance seems to have been on a sufficient basis to infringe upon comfort, a condition, by the way, which is scarcely to be counted when confronted by the enthusiasm which was displayed by the veteran autoists who have always lent support to Portland's effort, and the keenness of the prospectives who hovered over the automobiles which reached more nearly to the level of their respective ideals. The exhibitors, a number of which represented important local industries, included in their wares a class of cars which measure up to the exacting requirements of the keen New Englanders.

THE EXHIBITORS AND THEIR WARES AT PORTLAND

Apperson	Russell & Company
Buick	Buick Motor Company
Cadillac	Mank-Stuart Motor Company
Elmore	F. R. Parker & Company
E-M-F	Maine Motor Carriage Company
Ford	Spear Auto Company
Flanders "20"	Maine Motor Carriage Company
Fuller	Fuller Auto Company
Grout	Portland Motor Mart
Inter-State	Portland Motor Mart
Knox	The Portland Company
Maxwell	Stoughton-Folkins Company
Marion	Frank F. Wentworth
Mitchell	L. C. Gilson Automobile Company
Oakland	Stoughton-Folkins Company
Overland	Frank F. Wentworth
Oldsmobile	Stoughton-Folkins Company
Palmer-Singer	Taxicab Cab Company of Maine
Paterson "30"	W. A. Paterson Company
Peerless	Maine Motor Carriage Company
Pope-Hartford	Maine Motor Carriage Company
Premier	L. C. Gilson Automobile Company
Rambler	Stoughton-Folkins Company
Regal	Portland Motor Mart
Reo	F. Burgess
Selden	F. A. Nickerson Company
Stanley	L. C. Gilson Automobile Company
Speedwell	Portland Motor Mart
Stevens-Duryea	Maine Motor Carriage Company
Studebaker	Bullock-Goodwin Company
Velie	Pine Tree Auto Company
White	Portland Motor Mart
Warren-Detroit	Harrison & Tenney

BIG EASTER SHOW FOR PITTSBURG

The fact that the fourth automobile show in Pittsburg will be an Easter event has led the committee to provide a unique feature in the opening ceremony. A monstrous Easter egg suspended in the middle of the great auditorium and on the stroke of eight on opening night Mayor William A. Magee will pull a string opening the Easter egg and showering Easter blossoms on the crowd.

This show given under the auspices of the Automobile Club of Pittsburg opens in Duquesne Garden, Saturday, March 26, and indications point to the most successful exhibition of this kind ever held in smoky city. The committee in charge will spend more than the usual amount for lighting purposes alone, and the brilliancy of the Garden will surpass any previous illuminating effect. Entries for the show to date are large, 36 automobile firms have engaged space and about 30 accessory exhibitors will be taken care of. Following is a complete list:

Arlington Automobile Company, Center avenue, Pittsburg; Buick Motor Car Company, Baum street, Pittsburg; East End Automobile Company, Baum street, Pittsburg; Ford Motor Car Company, Highland avenue, Pittsburg; Fort Pitt Motor Manufacturing Company, New Kensington, Pa.; Franklin Automobile Company, Baum street, Pittsburg; L. Giesenkamp Company, Penn avenue, Pittsburg; the Hiland Automobile Company, Center avenue, Pittsburg; Inter-State Sales Agency, Center avenue, Pittsburg; Keystone Automobile Company, Center avenue, Pittsburg; Kline-Kar Motor Company, Hay street, Williamsburg, Pa.; H. Lang Wagon Company, S. St. Clair street, Pittsburg; Larimer & Lowry, West Newton, Pa.; Liberty Automobile Company, Center avenue, Pittsburg; Martin & Mars, Forbes street, Pittsburg; Maxwell-Briscoe Company, Forbes, and Meyran avenue, Pittsburg; Mutual Motor Car Company, 5518 Walnut street, Pittsburg; McAlister Brothers, Penn avenue, Pittsburg; McCurdy-May Automobile Company, Baum street, Pittsburg; Pennwood Auto Supply Company, Fulton Building, Pittsburg; Pioneer Auto Company, Baum street, Pittsburg; Pittsburg Automobile Company, Grant boulevard, Pittsburg; Pittsburg-Mitchell Company, Baum street, Pittsburg; Pittsburg Speedway Motor Company, Ltd., Wilkinsburg, Pa.; Premier Sales Company, Beatty street, Pittsburg; Pullman Motor Car Company, York, Pa.; Sebring Motor Car Company, Sebring, O.; Speedwell Automobile Company, Center avenue, Pittsburg; Standard Automobile Company, Baum street, Pittsburg; Studebaker Auto Company, Forbes Field, Pittsburg; E. J. Thompson & Company, Penn avenue, Pittsburg; Urling & Company, Center avenue, Pittsburg; Vestal Motor Car Company, Highland avenue, Pittsburg; The White Company, Beatty street, Pittsburg; Wilkinsburg Auto Garage, Wilkinsburg, Pa.; the Winton Company, Beatty street, Pittsburg.

CHALMERS OFFICIAL GLIDDEN PATHFINDER

After a careful consideration of the competitive proposals submitted by a number of manufacturers for the privilege of furnishing the Official Pathfinding Car for the 1910 Glidden Tour, the Contest Board has awarded this privilege to the Chalmers Motor Company, of Detroit.

The Chalmers car which is to lay out the route will commence its work sometime during the month of April, as soon as the roads are in a fit condition to determine the most practicable route.

The futility of the efforts of a car of another make than the Chalmers, now attempting to go unofficially over the road, and the unreliability of the road information which such car can obtain at this season of the year is self-evident. The roads over the proposed route of the tour are in such condition at the present time that the route which any car would have to take would of necessity include many detours and be entirely at variance with the route which will be selected by the Chalmers Official Pathfinding Car when it goes over the territory in the proper season.

Intending entrants in the tour should not be misled by the road reports from any self-appointed or unofficial pathfinding car making an unseasonable run, but should wait for the reliable and authentic information which will be contained in the reports of the "official pathfinder."

The Contest Board also contemplates the changing of the tentative route in some of its important particulars.

Contest Board, American Automobile Association,
S. M. Butler,
February 28, 1910. Chairman.

WISCONSIN STATE A. A. TOUR

The Wisconsin State Automobile Association is planning for the first annual state tour, with President Moore as a leading promoter. The American Automobile Association has granted the Wisconsin State Automobile Association an official sanction. The tour will probably start at the Public Library, Milwaukee, thence to Whitewater, and along the north shore of Lake Geneva to Beloit, where the first night control will be established. The second day's run is from Beloit through Janesville, Monroe to Madison for overnight stop. Madison to La Crosse is planned for the third day's run. Eau Claire to Chippewa Falls on the fourth day; thence to Marshfield to Wausau, Merrill on the fifth; the sixth to Appleton; thence from Appleton to Green Bay, Manitowoc, Sheboygan to Milwaukee on the seventh. This tour is to be open to private owners as well as dealers and manufacturers and the profit derived will be used exclusively for measuring roads, placing signboards and marking turns, also for working up legislation, prosecution of reckless drivers, protection of members and the creation of a legal fund.

IMPORTANT R.R. SHIPPING CONCESSION

In the matter of automobile shipment, J. S. Marvin, general traffic manager of the National Association of Automobile Manufacturers, announces a change in the rules which will simplify matters considerably in securing cars at the factories for automobile transportation.

It is known that many factories require freight cars no longer than 36 feet; also that railroads frequently supply 40-foot cars with a proportionately higher charge. Rather than wait indefinitely for 36-foot cars, many manufacturers, to effect prompt delivery, have used 40-foot cars at considerable additional expense in the matter of freight charges. The new ruling effective April 1, 1910, provides that when factories order 36-foot cars and the railroads are unable to furnish cars of that length said railroads will send instead 40-foot cars, with freight charges computed on the 36-foot basis, provided, of course, that machines loaded in the 40-foot cars are small enough to have been shipped inside of a 36-foot car.

BUDLONG ACCEPTS HEAD OF N.Y. DEALERS

At a special interview with M. J. Budlong, president of the Packard Automobile Company of New York, the representative from The Automobile ascertained that the delay on the part of Mr. Budlong in accepting the presidency of the Licensed Automobile Dealers' Association of New York was due to press of business, and the aggregate of private interests, which, as Mr. Budlong stated, absorbed so much of his time that he felt called upon to explain to his associates that he would have to more or less neglect important matters, were he to accept the presidency of the association. Events proved too strong for Mr. Budlong, and the unaminous demand on the part of the members of the association, which was vigorously supported by the committee, resulted in his reconsideration of the situation and the final acceptance of the presidency of the association. It is too early in the life of this new member of the association family to expect action which could be construed as anything more than routine, and from what the new president states, it is logical to conclude that the good of the industry will be consulted, in every case, before a serious campaign will be inaugurated.

George W. Bennett, New York manager of the White Company, has been made vice-president; C. P. Skinner, New York agent for the Mitchell car was elected secretary and treasurer.

N. Y. AUTO TRADE ASS'N EXPANDS

Plans were launched for a very material expansion in the membership and scope of the New York Automobile Trade Association at the meeting of the board of directors, held recently, and a vigorous campaign has been started to bring the membership up to the standard and in keeping with the number of concerns handling automobiles and supplies and operating garages in New York City. It is expected that 40 or 50 concerns will become members during the next few weeks. The association's credit department will be enlarged and broader plans are on foot for making more effective standardization of the garage division. In this latter work, a special committee in charge has plans under way to standardize the prices of garage charges, in the matter of storing cars and the prices of gasoline oil and other supplies.

An auxiliary committee will be established for the purpose of correcting many abuses and will work with the city authorities to stop irregularities, and to secure proper legislation on matters of interest in the automobile fraternity.

NUCKOLS TO BE PRESIDENT OF E. V. CO.

The latest inside report from Hartford, which, however, is not officially confirmed, gives to H. W. Nuckols the presidency of the Electric Vehicle Company, which concern, it will be remembered, recently joined the coterie which made up the United States Motor Company with an aggregate capitalization of $16,000,000. Mr. Nuckols has been with the E. V. Company from its inception, and occupied the position of treasurer and secretary up to the time of the receivership, and was appointed receiver, in which position his skill and efficiency brought the company out of the woods. Benjamin Briscoe, president of the Maxwell-Briscoe Company, and the prime mover in the big United States corporation, was not to be reached before going to press, but he will no doubt come out with an official statement confirming the above within a short time.

STREET CAR STRIKE KEEPS AUTOS BUSY

The automobile is again proving its worth in Philadelphia, where, for a time, the entire stoppage of the trolley service—due to the strike—practically tied up the city. Not alone were the police officials and roundsmen transferred from point to point, but the taxicab service was worked to the limit night and day; in fact, aside from the use of several hundreds of horse-drawn vehicles, automobiles were practically the only means in transportation service that turned a wheel.

GOODRICH IS WELL HOUSED IN BOSTON

In the commercial progress of New England during the past ten years the tire and rubber business has undergone a wonderful development, and a shining example of the individual prosperity of one firm is shown in the remarkable growth of the business of the B. F. Goodrich Company, which has recently taken possession of its new six-story building at 851-857 Boylston street. The home of the B. F. Goodrich Company is in Akron, Ohio, and throughout the United States it maintains a number of central distributing plants with Boston as a base of supplies for New England territory. When the automobile industry was in its infancy about nine years ago, Howard Limric came to Boston in charge of the Goodrich branch, which was then located on the second floor of a business block on Kingston street and the entire force of the tire department consisted of four men. As the automobile began to grow in popularity there was a corresponding increase in the demand for Goodrich tires and with the increase in business the company moved to Columbus avenue where it soon outgrew its facilities for doing business and finally made plans for the erection of a building designed for its particular branch of trade. The little acorn planted on Kingston street has now grown to be one of the giants in its line employing a force of sixty men in the handsomely new appointed building which with its six floors and basement gives a total of 30,000 square feet of floor space. The building has a 44 foot front on Boylston street and is 97 feet deep with a 15 foot sidewalk set back. The building is of reinforced concrete with granolithic floors and is as near fireproof as up-to-date construction methods will permit. In general design the building is after the modern French style and the architects, Kendall & Taylor, have worked out a very pleasing front of white glazed terra cotta and a rich effect is produced by the use of marble dados for the two entrances. The salesroom is on the first floor, taking up almost the entire width of the building. This salesroom is finished with an eight foot wainscoting of Central America mahogany and the floor covering is of rubber interlocking tiling. It is a very pretentious looking salesroom and no expense has been spared in its equipment. In the rear of the salesroom is the shipping room which is so arranged that all deliveries are made through one door and the goods received come in by another door so as to avoid any confusion. In the delivery department the express company messengers receive their goods from individual compartments and in order to facilitate matters a private shipping court runs into the building affording ample room for automobiles and express wagons without blocking the alleyway in the rear of the building. The general office and private offices are located on the second floor. These rooms are finely equipped for the purposes for which they are intended and in the private offices the furniture is of fumed oak.

The third and fourth floors are used exclusively for the storing of tires. The different sizes are kept on separate racks and these are adjustable so that they can be used for any size of tire. These floors have a capacity for storing 9,000 tires.

The fifth floor is a huge storeroom for the extensive line of mechanical and specialty rubber goods manufactured by the B. F. Goodrich Company. These articles include most everything made of rubber except mackintoshes. The top floor is used for a repair and adjustment department with an equipment that meets the requirements of the business in a very satisfactory manner. The basement of the building is used for bicycle and automobile sundries with a complete list of articles that come under the classification of accessories. In designing the building the architects have sought to produce the best of facilities for the handling of this business and the elevator service is all that could be wished for with an electric passenger elevator in the front of the building and a freight elevator in the rear, in addition to an electric lift.

BIG MILEAGES IN WESTERN BAD LANDS

From New Mexico comes the story of James Stocker, a mailman, of Torrence, New Mexico. Stocker has three 1905 two-cylinder opposed horizontal engined Buicks with which he claims to make the 110 miles between Torrence and Rockwell, New Mexico, every day with the Government mails. He says that from January 15, 1906, to the present these three cars have missed but three days and have always been on time. According to Stocker's story, the only time the cars were ever tied up was during a three-day blizzard when the snow became too deep for anything but snow-shoes or skis. Stocker has a government mail contract and his cars run every day having each made 165,000 miles since being placed in commission.

BRIDGEPORT CLIMB TO HAVE MORE ENTRIES

At Bridgeport, Conn., will occur the fifth annual hill climbing contest of the Automobile Club of Bridgeport on May 30. Preparations are being made to have this event more elaborate than ever before, and additional safeguards will be provided for both spectators and contestants, with the State Militia to guard the course. The McMurty electric timing system will be used as before, and along the rack, at 1/8 mile intervals telephones will be placed. It is expected that there will be one hundred entries for this event—at least fifty more than last year.

Farewell banquet given at Yates Hotel by Automobile Dealers' Association of Syracuse on occasion of departure of F. R. Bump, sales manager of the H. H. Franklin Mfg. Company to become sales manager of the Owen Motor Car Company, of Detroit, Mich.

WITH THE AGENCIES

One of the cars of which Massachusetts is proud; a Grout car, under the guidance of William Adams, chief tester of the Grout Automobile Company, Orange, Mass. The snow almost hub-deep makes little difference to this sturdy and powerful car.

The Swinehart Tire & Rubber Company have just opened a new branch in Philadelphia at 1437 Vine street, with D. Thos. Keenan as manager. A complete line of solid and pneumatic tires will be carried in stock at the new branch, and Mr. Keenan is well known, having been identified with the automobile and accessory business for several years. With its increased factory facilities the Swinehart Company will be able to handle a large volume of business during the year of 1910, and some good contracts have been received by the company from manufacturers located in the Philadelphia territory.

George B. Craven, formerly of Detroit, has been appointed distributor of the E-M-F and the Flanders cars. He will have headquarters at Cleveland. Twenty-one E-M-F cars have been received by the branch and these will be placed on exhibition in one of the most commodious salesrooms in Cleveland. Mr. Craven has been connected with the automobile industry since its inception, and for some time was a member of the staff of the General Motors Company at Detroit.

Chase motor wagons have entered the San Francisco market. William H. Durphy, formerly sales manager of the Chase Company, has opened an agency in that city. In this connection it is said that A. M. Chase, president of the Chase Motor Truck Company, reports that it has closed a deal with Leyland Motors, Ltd., of London, England, for 1,200 Chase wagons, to be taken in five years.

Fred R. Hill and Harry Weber are now connected with the Stewart & Clark Mfg. Co. traveling forces. Mr. Hill will make his headquarters in Philadelphia, covering Pennsylvania and Southern territory. Mr. Weber will be in Kansas City to cover the Southwest in the matter of handling Stewart speedometers. Both were formerly with Herz & Company.

Edward Miller has opened a salesroom at 705 Ann street, Columbus, O., where he handles the Premier. Mr. Miller was formerly associated with W. K. Mathews in the Miller-Mathews Company which handled the Jackson and Premier. After the partnership was dissolved the O. G. Roberts Company took the Central Ohio agency for the Jackson.

The Seamless Rubber Co., of New Haven, Conn., has just opened a New York branch office, located at 2002 Broadway, where a full line of this company's goods will be handled. Principally the Bragg stitched tire will be handled, or at least pushed, this tire having made a big hit at the recent New York shows.

The Ohio Auto Sales Company is the name of a new sales agency for Columbus, O., which has established a temporary office at 27 West Russell street. Later it will move into a room at Goodale and Front streets. W. B. Zimmerman is general manager, and the company is Central Ohio agent for the Ford.

The Automobile Accessories Company, of Pittsburgh, is opening at Centre avenue and Beatty street. This concern has the exclusive agency for the Pennsylvania tire in the Pittsburgh district. Wm. B. Yoder is manager.

The Weaver-Ebling Automobile Company, 2230 Broadway, New York, have taken an agency for the Harley-Davidson motorcycle. Their territory includes New York, Long Island, Staten Island, Westchester and vicinity.

H. C. Whittaker, president of the Wheeling Corrugating Company, has taken the agency for the Rainier car in the northwestern section of West Virginia and the southeastern section of Ohio, with headquarters in Wheeling.

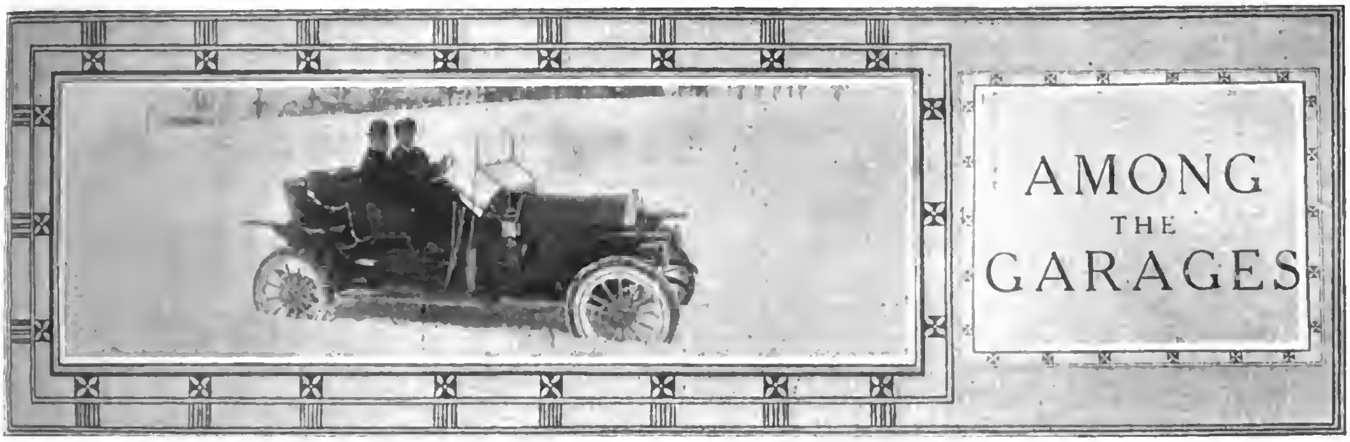
The Early Automobile Company, of Columbus, O., added two more agencies to its line by taking the Southern Ohio rights for the Whiting and the Warren-Detroit. Delaware County is also included in the territory.

George D. Knox, local agent for the Peerless and the Hudson in Hartford, Conn., has completed alterations in the general offices, 210 Pearl street, which will permit of the display of cars on the office floor.

The Way-Mitchell-Rigden Company, Cleveland, Ohio, agents for Republic tires and Stromberg carbureters, has secured the agency for Harris oils.

Wayne Davis, well known in the Philadelphia trade, has secured the agency for the Everitt "30."

J. Fortesque, secretary of the Bay State Automobile Association, one of the men who have helped it to its present success.



A typical Winter scene, in which a Speedwell roadster plays a prominent part. Automobiling is coming more and more into prominence as a Winter sport, and the number of owners who lay up their cars during this season is diminishing every year.

Mobile, Ala., has a new garage, conducted by the Ross Motor Company. Alfred G. Ross, the manager, has been with Bloch Brothers and the Mobile Auto Company for the past four years, so is no stranger to the selling end. He is also the secretary of the Mobile Automobile Club and vice-president of the Alabama Automobile Association. The Ross Company has an up-to-date garage, and will handle the Moon and the Rapid commercials.

Halladay automobiles will be handled in Georgia by Boyd-Patterson Company, with headquarters at 287 Edgewood street, Atlanta. The Streator Motor Car Company, maker of this well-known automobile, is pushing out, and in selecting this company as distributor, wisdom has been displayed. The establishment in Atlanta is well equipped with every facility, including tools, mechanics, and a wealth of experience.

The new garage building for the Ford Automobile Agency, of Wichita, Kansas, now in course of construction, will measure 140 ft deep by 50 ft. wide, and three stories high. The first floor will be the salesroom for cars and accessories, while the second will be storage and machine shop, this being very complete. The top floor will be for general repairs and painting.

The garage and salesrooms of A. Vernon Hart, Rochester, N. Y., were badly damaged by fire recently, and several cars were scorched and otherwise injured. The estimated loss is $10,000. Mr. Hart handles the Thomas Flyer, Oakland and Columbus electric.

David J. Post, president of the Post & Lester Company and treasurer of the Veeder Mfg. Co., both of Hartford, Conn.

Kaeser & Wilbur, of West Hartford, Conn., have taken the agency for that vicinity of the Empire 20. The firm is located in a large garage on Farmington avenue, and has already made some desirable sales.

F. W. Conrad, of the Pacific Garage, Montesano, Wash., states that he used Diamond tires on a six-cylinder Franklin car, with an average considerably over nine thousand miles per tire.

PERSONAL TRADE MENTION

The Carpenter Steel Company announces that Fred A. Bigelow, formerly its representative in New England, has assumed charge of its Cleveland branch at 1304 West Sixth street. This is to be taken as a sign of much activity around Cleveland, especially in connection with steel as it is used in automobile work.

Tom Moore, formerly secretary of the Cleveland park department, has become connected with the Vail Motor Sales Company, of Cleveland, and will have personal charge of the selling end of the Clark car, for which the company has just taken the agency. The Vail Company is also Cleveland agent for the Empire.

P. D. Wagoner has been elected president of the General Vehicle Company, Long Island City, N. Y., succeeding Howard Hanson, who has withdrawn from the company. Mr. Wagoner brings to his new work a wide experience in engineering and commercial affairs, and under his administration the outlook for the future of the General Vehicle Company appears very bright.

Albert L. Bennett has joined the Colt-Stratton Company, Broadway and Sixty-eighth street, New York City, in the capacity of sales manager. He will direct the sales of the Cole "30" and Paige-Detroit, both represented in this territory by the Colt-Stratton Company.

G. W. Stephens, formerly advertising manager of the G & J Tire Company, of Indianapolis, has severed his connection with that company, and will enter business for himself in Chicago. Mr. Stephens will handle tires and accessories, possibly locating on Michigan avenue.

T. C. Whitcomb, formerly Rambler agent at Cleveland, has accepted a position with the Overland Motor Car Company, at Toledo. He will become assistant to General Sales Manager F. A. Barker.

E. C. Johnson, formerly sales manager of the Philadelphia branch of the White and Packard companies, will become general sales manager of the Bergdoll Motor Car Company on March 15. Mr. Johnson is at present in Jamaica.

C. H. Foster, patentee of articles manufactured by the Gabriel Horn Mfg. Co., of Cleveland, will be succeeded by H. D. Preston as sales manager. Mr. Foster finds it necessary to devote more time to the manufacturing end of this increasing business.

REALM OF THE MAKERS

The Knox Automobile Company has a large, modern plant in the suburbs of Springfield, Mass., a hustling Bay State town, which is celebrated for manufactures. The Knox factory is one of which any city, even Detroit, might be proud

Following a record month of production, in which not only the monthly but also the daily and every other Chalmers manufacturing record was broken, General Superintendent Reddig, of the Chalmers Motor Company, Thursday evening, tendered a dinner to 22 foremen and inspectors of the production dept.

The affair was a complete surprise to the men. Thursday morning H. L. Bill, assistant superintendent, spoke to each of the men, telling them to report in the office at 6 o'clock for a lecture from Mr. Redding. All were told to send word to their families that they might be kept late. Then, when all were assembled, they were led to waiting automobiles and whirled to Dobson's roadhouse, Grosse Pointe, where the dinner was served at 6:30.

Hugh Chalmers, president and general manager of the company, was called out of the city and so could not attend the dinner. A letter from him to the men was read by Mr. Reddig.

"The car luxurious"—a strikingly handsome landaulet body mounted on the 15-30 horsepower Stearns chassis, was one of the most attractive features of the immense automobile show in the Coliseum at Chicago recently. The comfortable and roomy body, attractively finished in whipcord, contained all the little luxuries so desired by those of good taste. Speaking tube, clock, note pad, cigar lighter, ash tray, interior electric light (Tungsten burner), toilet set, vanity case and other little conveniences united in producing one of the handsomest landaulets ever exhibited in the Windy City. This car, being a landaulet, opens in Summer, providing an ideal car for fair weather use. Practically the same body is furnished in the limousine type. The Stearns exhibit also embraced touring cars, toy tonneau runabouts and polished chassis of both the 15-30 and 30-60 models.

George Pope, treasurer of the Pope Mfg. Co., which makes the Pope-Hartford, a well-known New England product.

A two-cylinder Maxwell Junior climbed the front steps of the Tarrant County court house, Fort Worth, Tex., went through and glided down the north steps, in the presence of a crowd of 500 people, passing through the severe test without even a flattened tire, scratch or break of any kind. Tom Abbott, of the Mulkey Auto Company, drove the car and he with one passenger pronounced the climb and steep descent pleasant and comfortable. It is said that no other car has ever performed this feat, although a four-cylinder machine mounted the front steps, but stopped there.

The Thomas Motor Cab Co., Buffalo, is in full possession of the new plant at 1738 Elmwood avenue, which is devoted entirely to the manufacture of Thomas taxicabs. It is reported that the demand for Model G taxicabs is so pressing that the new facilities are just in time, and, under the better conditions now available, it is expected that the output will maintain some kind of a pace with the strong demand.

The Gabriel Auto Company has been incorporated under the laws of Ohio, and in addition to making a thirty-horsepower car, to be known as the Gabriel, will act as state agents for the K-R-I-T. The Grabowsky truck will also be added to the line. The company is an outgrowth of the W. H. Gabriel Carriage & Wagon Company, which has operated a large plant in Cleveland for years.

On or about June 1 the Fal Motor Co., of Chicago, will have a new factory ready for occupancy. This will give the company 250,000 square feet of much-needed floor space, with its own power plant, and, best of all, a half-mile testing track. When the new factory is occupied the company will gradually work into the manufacture of all parts going to make up the Fal-Car.

O. B. Henderson, sales manager of the Baker Motor Vehicle Company, states that sales for 1910 delivery show the greatest increase in the history of the business. The new shaft-drive models are the most popular, and it is said that agents for this car have nearly doubled their orders for 1910 over 1909.

The Pierce-Arrow Motor Car Company, of Buffalo, contrary to its custom, announces the placing on the market of the new model soon after the beginning of the year. It is said that owing to the necessity of time for the manufacturing of these cars, orders for them will not be accepted after April 1.

It is said that during the coming year George Robertson, the noted racing pilot, will use Continental tires and demountable rims on various cars he will drive.

Systematic and economical organization is the keynote in all modern automobile plants, and is necessary no less in the administrative offices than in the workshops. This is a view of the Goodrich Boston branch.

Members of the Maryland Legislature have taken a number of exceptions to the automobile bill prepared by Col. Sherlock Swann for the Automobile Commission. A number of the legislators object to the provision for the Motor Vehicle Commissioner at $3,000 a year. It is said that these objections are made upon the ground that it seems that the salary of the Secretary of State, who they believe to be a greatly underpaid official, should be increased, and by amending the bill this can be done, provided no Motor Vehicle Commissioner is appointed.

From Los Angeles comes a report that arrangements have been made whereby Ralph De Palma will in the future pilot a 200-horsepower Fiat car owned by W. C. Arnold. The next appearance of the speed monster with De Palma at the wheel will be at the inaugural meet of the new board motordrome near Los Angeles. In view of this, it is possible that Oldfield and his Benz may be matched with the Fiat, although, as previously noted, negotiations in this direction are for the time being suspended.

Lieutenant Shackleton, the British South Pole seeker, is an ardent motorist. During his recent journey into the unknown South he used an automobile, and in a coming lecture in New York he expects to make public some of the details in this particular. Benj. Briscoe, president of the Maxwell-Briscoe Motor Company, has expressed a desire to build for the lieutenant a car which will surmount all possible difficulties of the polar journey.

The Delaware Aero Club has been incorporated under the laws of Delaware, with a capital of $100,000, by the following: David Snellenburg, George W. Crowe, Grantley P. Posteles, William L. Dockstader, John A. Montgomery, John G. Gray and Robie Seidlinger, all of Wilmington. Mr. Seidlinger has invented an aeroplane which it is proposed to build and test, and if it proves a success it will be exploited.

The Folsom Manufacturing Company, South Bend, Ind., maker of automobile accessories, has contracts with the Moon Motor Company, of St. Louis; Haynes, of Kokomo; Buckeye, Rider-Lewis and a number of other companies. for under-pans, tanks, and other sheet metal work for automobiles.

A. Leubner & Son, liverymen at Wausau, Wis., have decided to add several automobiles to their equipment, realizing that the horse-drawn vehicle is fast passing. Two cars are being used at the start, but the demand for the self-propelled vehicles is so great that more must be added.

The Pittsburg Automobile Academy is a new school for drivers at 6211 Howe street. W. H. Schmitz, president of the company, is an old Pittsburg automobile dealer, and H. P. Johnston, former automobile editor of the Pittsburg *Press*, is also connected with the school.

The Todd Rubber Company, Hartford, Conn., has removed from 30 Church street to 279 Trumbull street to more commodious and central quarters. Aside from the repair of tires a general accessory business is done.

The Silent-Motor Car Company, of Pittsburg, Pa., has been formed by Carl C. Conkle, Pittsburg, Pa.; Julius Sturtevant, New Kensington, Pa.; John W. Maesch, Beaver Falls, Pa., and G. W. Dorsey, Jr., of Wilmington, Del. It has a capital of $300,000, and will manufacture automobile parts.

The Great Western "30" will be entered in a large number of track races and hill climbs during the coming season. F. B. Thornburgh, the representative of Wheeler & Schebler, will drive.

The Pittsburg Auto Equipment Company, of Pittsburg, has bought the entire plant of the Union Auto Repair Company, on Collins avenue, East End, whose wind shield it has been selling for six months.

The Derain Motor Company, of Cleveland, has increased its capital stock from $40,000 to $60,000 by papers filed with the Secretary of State recently.

The Schoellkopf Auto Radiator Company, of Cleveland, has been incorporated with a capital stock of $25,000 by William Schoellkopf and others.

The Queen City Motor Car Company, of Cincinnati, has been incorporated with a capital stock of $10,000 by F. M. Bering and others.

The Cleveland Auto Trading Company, of Cleveland, has been incorporated with a capital of $5,000 by C. K. Halle and others.

Alfred Reeves, late of the American Motor Car Manufacturers' Association, now general manager of the A. L. A. M.

PROMINENT ACCESSORIES

The Diamond Chain & Mfg. Co. calls attention to the new method of housing and adjusting the douhle Diamond chain drives of 1910 Chadwick cars as a most practical arrangement for making chains give good service.

The radius rod, which is a manganese hronze casting, forms the greater portion of the inside of the case and is provided with a slide to permit chain adjustment. The centers of the radius rod are respectively the centers of the jack shaft and rear axle, so that there is no tightening or loosening of the chain from the up-and-down spring movement, and the chain can be correctly adjusted at any position of the springs. This construction has another advantage in that the case can be built very narrow without the danger of side slapping and its attendant noise.

Link of Diamond chain

A special Diamond chrome nickel steel chain is used and the sprockets are shaped to avoid "huzz" as the chain rollers strike the teeth. This noise is usually caused hy insufficient luhrication after the chain has become filled with dust and dirt. The chains of a Chadwick car are first adjusted to make the drive as nearly noiseless as possihle and are then luhricated with a heavy grease, which the case retains.

The addition of the aluminum cases tends to muffle the noise still further. A felt washer where the case encloses the rear wheel drum further prevents dust from reaching the chains.

The chain drives of Chadwick cars enahle the use of an I-heam section rear axle which is enormously strong and very light in weight, the differential heing placed up in the car in order to load the springs and promote easy riding. With this construction the heavy dead weight of the differential is not directly supported by the rear tires, a feature which materially decreases tire trouhles and expense.

The direct forward pull from the top of the sprockets on each side also gives easier riding qualities than the tipping action in shaft-driven cars. Further it is impossihle for road shocks or ohstructions to throw the rear axle out of alignment, which may happen in shaft-driven cars with a consequent power loss.

DeLuxe gas tip burner

Prominent among the acetylene hurners on the market is the Alco, which is not connected with the automobile of that name, hut is the product of the American Lava Company, of Chattanooga, Tenn. This embodies the usual principles of acetylene hurners; that is. it is forked in shape, with a passage for the gas in each branch, so arranged that the two streams of gas impinge on each other to give a fan-shaped flame. The gas passages are slightly enlarged at their ends and have holes drilled in to admit air, so that the gas is diluted or mixed with part of the air necessary before it issues from the nozzles.

The pillars of the jets are turned from solid hrass, heavily nickel plated. The hurner proper, the branched part, is screwed into the pillar and is cemented in place, so as to make leaks absolutely impossihle. The hurner is made of genuine Nuremberg steatite, which is the hest and most reliable material for the purpose.

Volier horn, a new variety

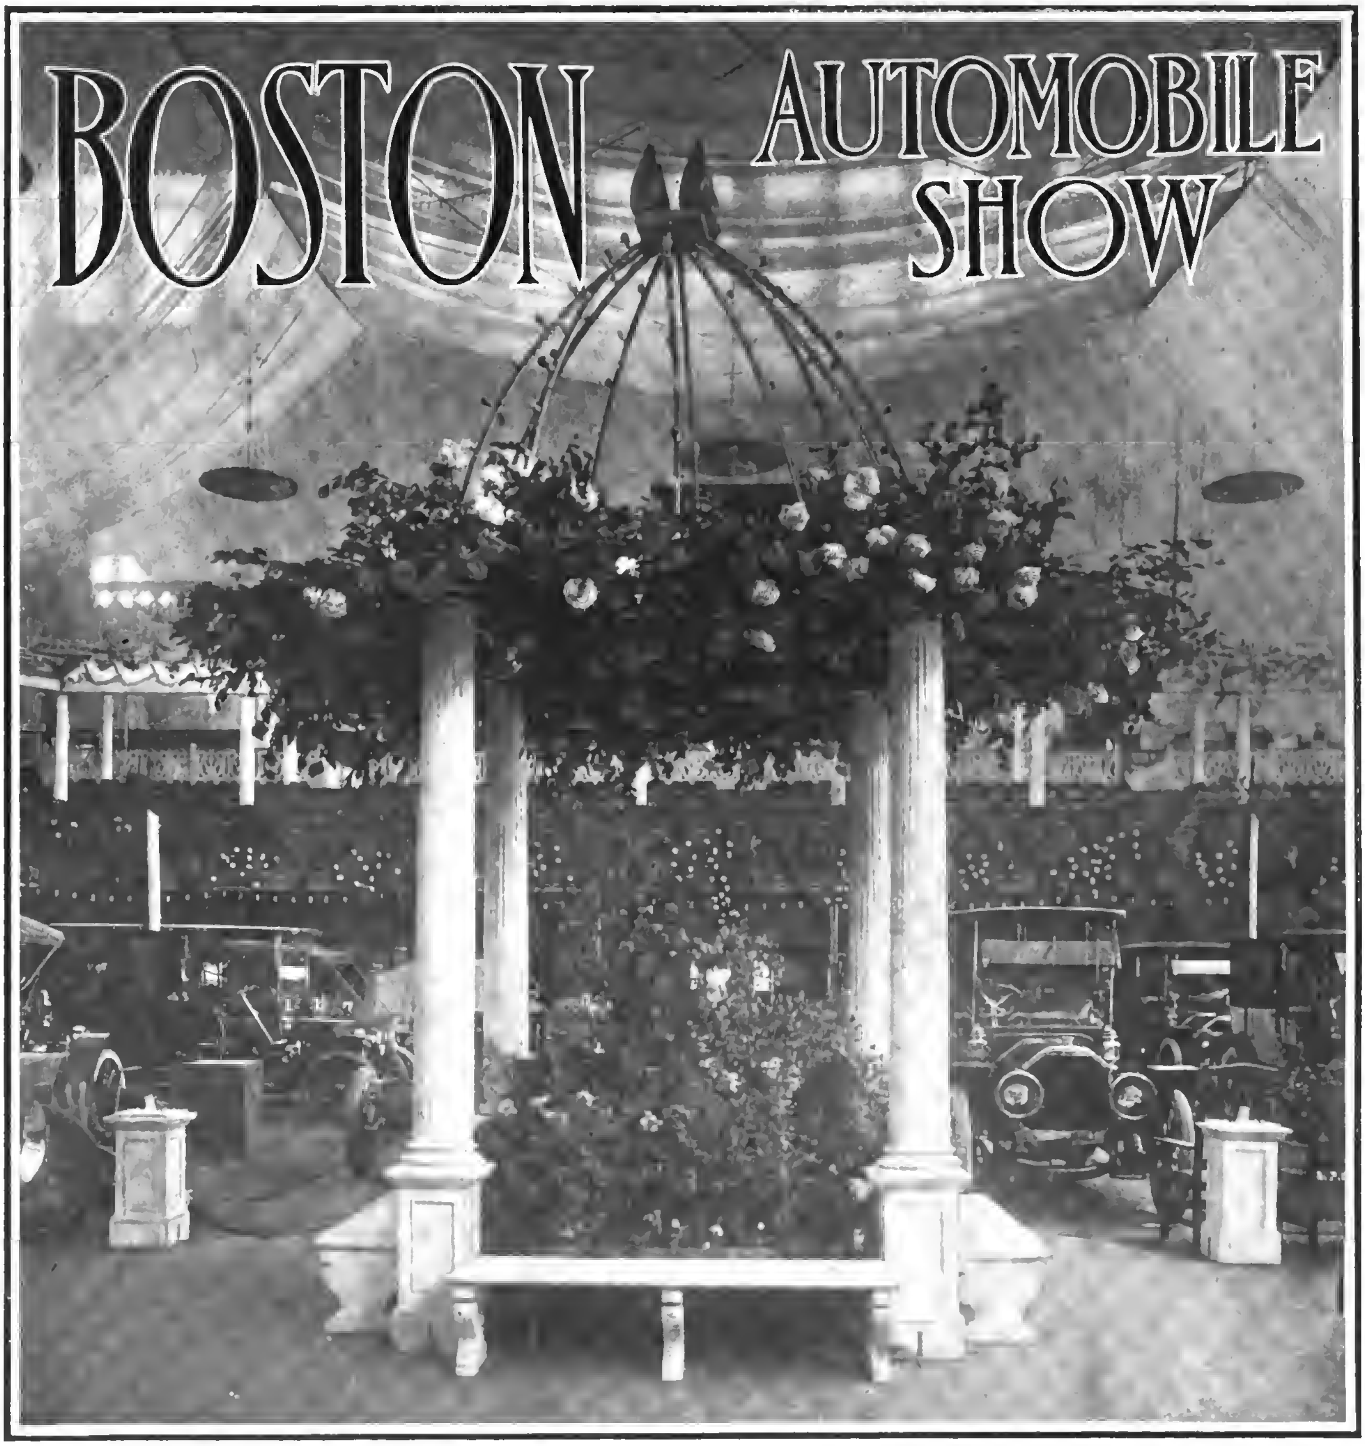
The 1910 models of the Volier horns, formerly handled by the American Brass Products Company, of Hartford, Conn., are now made by that company in its American factory in accordance with French methods. This horn is claimed hy the maker to mark the perfection of graceful design; in both finish and workmanship it is equal to the hest French product.

The most favored model is the double-turn horn, the double-turn feature of design making the note very deep and musical. This quality makes them a dangerous competitor of the recently invented mechanical horns and sirens, which otherwise would have a clear field for automohiles intended for touring. It takes a good loud noise to clear the road in many cases, and the douhle-turn horn is the only one of the hulh-operated variety that is capable of producing it. All Volier horns are fitted with chemically cured hulbs and with reeds of a special non-corrosive metal. The horn proper is of spun hrass of sufficiently heavy section, and the five pieces are securely joined together. The horn is made in the usual styles, with or without the flexihle tube.

E. E. Sweet, engineer for the Cadillac Motor Car Company

Vol. XXII NEW YORK—THURSDAY, MARCH 10, 1910—CHICAGO No. 10

THE AUTOMOBILE

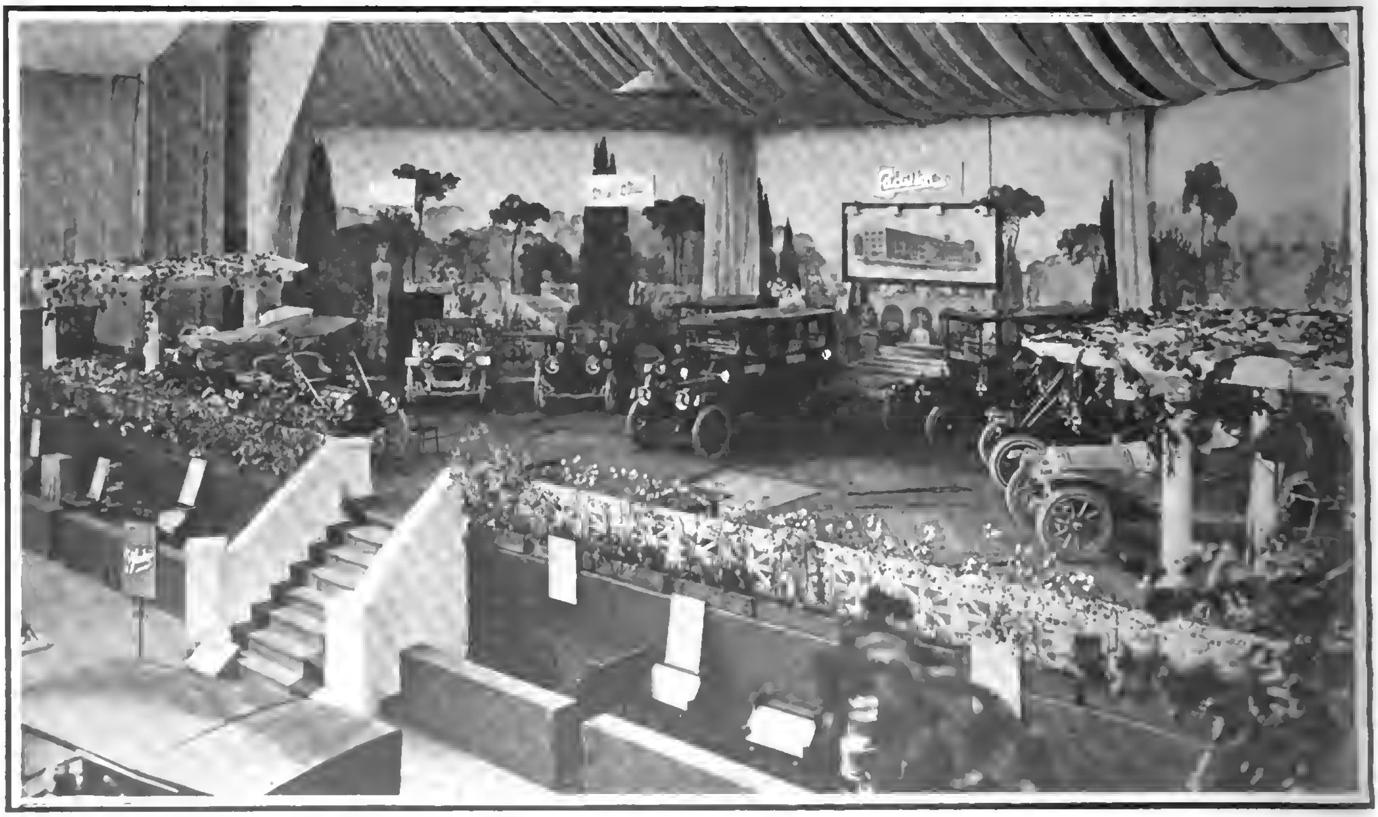


BOSTON welcomed the Eighth Annual Automobile Show which is being run under the auspices of the Boston Automobile Dealers' Association, under the direct management of Chester I. Campbell, whose success last year as a show manager was so marked that he was given carte blanche by the Board of Directors, when it was decided to make this year's event an epoch-making example. It was thought last year that the show decorations, since they were modeled after an art motif which

Two Paths through the Apple Orchard; Beneath the Blossoms and Leafy Branches Appears the Selden Exhibit

was selected from abroad after a long and painstaking search, were scarcely to be exceeded, but the transplanted motif, however good it may have been, falls flat in the face of the effort this year. New England scenery in the Springtime offers many advantages, and in accepting it as the art motif, Manager Campbell, with his native instinct, struck the responsive chord and added the atmosphere, as it were, which brought an apparent illusion up to the standard of a reality.

The spectators, as they pass the entrance, come into view of an old New England apple orchard which was improvised by the simple expedient of transferring the bark of old apple trees to the columns which support the Hall, and the limbs of the trees were fastened to the columns in a way to complete the illusion. It took a hundred thousand clusters of apple blossoms, which look so real that one can scarcely tell that they were improvised. The old rail fences which were brought down from New England farms, complete the spectacle, but the daffodils which were in much profusion, arranged in boxes at points of vantage, added the finishing touch to the Springtime scenic undertaking. There were other floral effects and decorations to



Alvan T. Fuller, Showing the Packard and Cadillac, Occupied the Stage with Some Handsome Machines match, and each of the halls were given a sufficient dash of variation to induce mingled feelings of surprise and pleasurable anticipation to the enthusiastic and large audience, which awaited the opening promptly at 8 o'clock P. M. on Saturday, March 5, without formality, so that the spectators were wholly unprepared for what is now counted, by the show veterans of the greatest experience, as being a demonstration in force of the elegance which comes from simplicity and appropriateness, responding to the directions of the master hand.

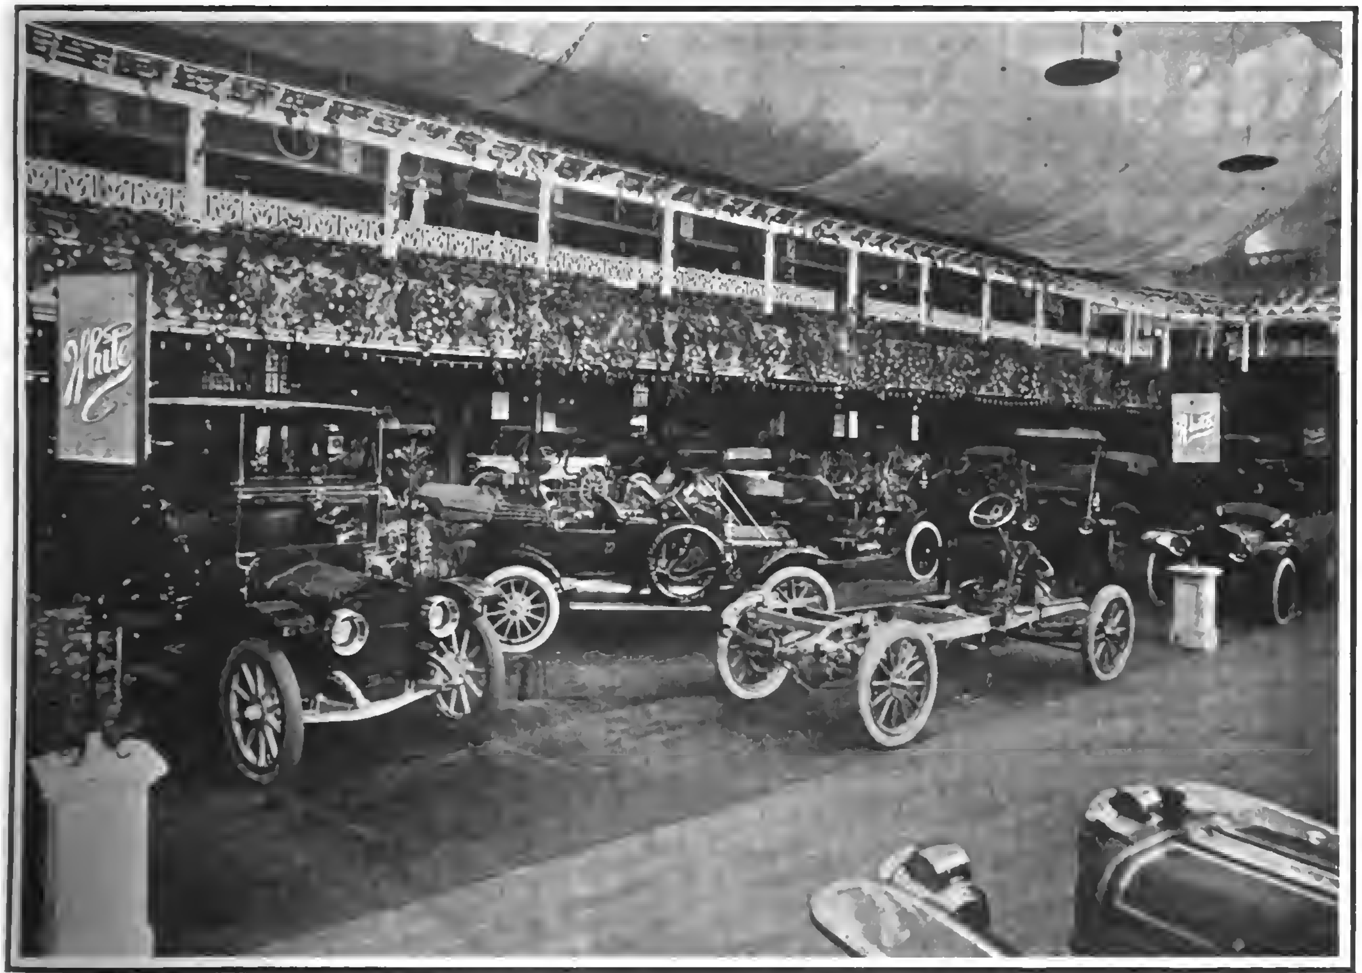
NEW ENGLANDERS OF NOTE OFFICIATE

To illustrate the breadth of character of the management of the Boston Automobile Dealers' Association, it is only necessary to point out that while the show is on, thus enabling the management to contact intimately with the respective makers and their agents, an organized effort is being made to borrow enough automobiles. drawing upon demonstrating cars heavily, to give all the poor children in Boston and its suburbs a ride which will survive in juvenile memory until prosperity overtakes the juveniles, when they may be able to ride in their own automobiles. It is this broad and varied effort on the part of the Dealers' Association and its members which has attracted public notice, and which resulted in a patronage on Saturday night when the show opened, that covered every foot of available space, and represented the substantials of this metropolitan community. Not only that, which was somewhat to be expected, but on later days the attendance was fully up to expectations.

The Board of Directors of the Boston Automobile Trade Association comprise: J. H. MacAlman, president; J. S. Hathaway, vice-president; A. F. Hinchliff, treasurer; Chas. E. Fay, director; J. W. Maguire, director; C. F. Whitney, director; E. A. Gilmore, director; F. E. Wing, director; A. P. Underhill, director; Chester I. Campbell, general manager.

There are 31 active members in the association: J. H. MacAlman, J. S. Hathaway, F. A. Hinchliff, George H. Lowe, Harry Fosdick, J. W. Maguire, Charles E. Fay, K. M. Blake, John L. Snow, Fred S. Smith, L. B. Butler, A. P. Underhill, F. E. Wing, A. T. Fuller, W. M. Jenkins, F. J. Tyler, J. M. Linscott, N. S. H. Sanders, C. F. Whitney, E. D. Dodge, J. W. Bowman, E. A. Gilmore, S. H. Baker, R. W. Daniels, Paul R. Curtis, Henry L. Johnson, A. B. Henley, Roy A. Faye, C. P. Rockwell and V. A. Charles.

The association was formed in 1902 and its first president was Kenneth A. Skinner. The first year resulted in a substantial foundation, and when J. H. MacAlman was elected to the presidency, the policy of the association was so crystallized that it has obtained in substantial form from that day to this, resulting in much good to the automobile industry, besides inspiring confidence. It is the policy of the association to maintain its membership strictly among dealers, and this policy is so rigidly enforced that prominence is never a sufficient excuse for membership—the first requisite lies in being a dealer. The obligations imposed upon the members are such that the public is adequately protected from every point of view.



The White Exhibit As Seen from the Stage, with a Gasoline Limousine and Chassis in the Foreground

AUTOMOBILES EXHIBITED AT BOSTON

On the opening night when the doors were swung back, an eager throng, rapidly filled the several Exhibition Halls and the 116 separate models of automobiles which were then ready for inspection became the main centers of attraction. The New England makes of automobiles were the first to be examined, among which the Columbia assumed extra importance, in

Looking Diagonally Across the Main Hall; the Galleries Were Pergolas Half-Hidden with Rose Blossoms

view of the recent combination of this make of car with the Maxwell and the other interests which form the United States Motor Company. The Locomobile from Bridgeport had its coterie of adherents, and the Knox, both in the commercial as well as in the pleasure section, was thoroughly engaged. Then, there was the Corbin of "full jewel" fame, and the Pope-Hartford besides.

The Alco exhibit created much favorable comment, due to the refinements which have been steadily going on despite the original high character of the Berliet, from which the Alco sprung.

View of Main Hall in the Direction of the Stage, with the Peerless Closed Cars in the Foreground

The two-cycle contingent made pilgrimage to the section occupied by the Atlas Company, where they were entertained sufficiently to gratify their desires. In the meantime the Stevens-Duryea booth was the center of attention of the many who take a particular fancy to the unit power plant, three point suspension, flywheel in front, and the perfect symmetry of the crankcase and extension which naturally follows. There was still a large number of the admirers of New England makes of automobiles and they gathered around the Metz booth where they were entertained instructively; the Metz is an unassembled product, and the company furnished everything necessary to the automobile enthusiast who prefers to be his own mechanic. So much for the product of the New England factories.

Excepting for the Anderson car which was listed to be exhibited but which failed to put in appearance in the Kline Kar booth up to the time of going to press, and the Morse, which is described elsewhere at some length, there were none which had not already been seen at New York or Chicago. That the showing was truly representative of the industry may be seen from the following list of the various classes. The automobiles actually on exhibition, counting makes, are as follows:

ELECTRIC PLEASURE CARS

Baker, Bailey, Columbia, Detroit, Firestone-Columbus, Rauch & Lang, Studebaker and Waverley.

STEAM PLEASURE CARS

White and Stanley.

GASOLINE PLEASURE CARS

Alco, Allen-Kingston, Autocar, Apperson, American, Austin, Atlas, American Simplex, Abbot-Detroit, Buick, Berkshire, British Napier, Black-Crow, Brush, Cadillac, Chalmers, Columbia, Corbin, DeMot, Paige-Detroit, Everitt, E-M-F and Flanders "20," Elmore, Empire, Fuller, Fiat, Ford, Franklin, Garford, Grout, Hudson, Haynes, Hupmobile, Herreshoff, Inter-State, Isotta, Jackson, KisselKar, Krit, Kline Kar, Locomobile, Lancia, Lozier, Lambert, Mercer, Mitchell, Mora, Matheson, Maxwell, Marmon, Marion, Morse, McCue, Midland, Ohio, Oldsmobile, Oakland, Overland, Packard, Pope-Hartford, Peerless, Pierce-Arrow, Premier, Pierce-Racine, Palmer-Singer, Paterson, Pullman, Royal Tourist, Rambler, Rainier, Reo, Regal, Renault, Stevens-Duryea, Studebaker, Stearns, Selden, Speedwell, Simplex, Schacht, Standard, Stoddard-Dayton, Thomas Flyer, Velie, Warren-Detroit, Welch, Winton, and White.

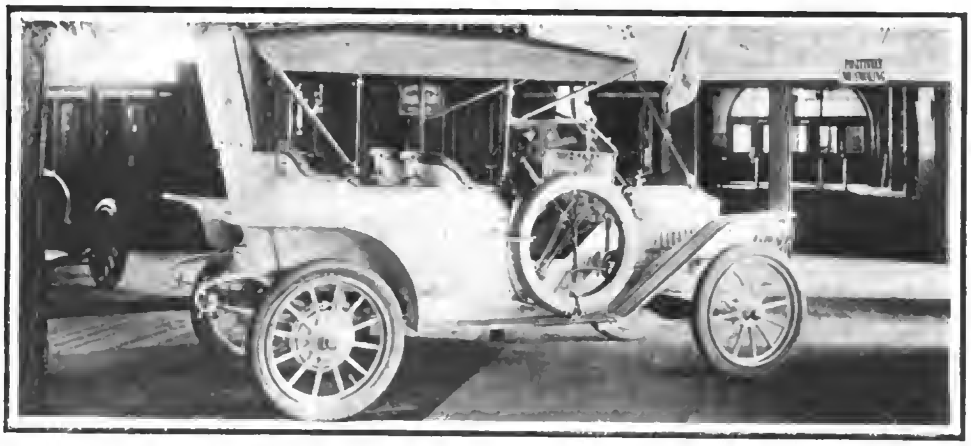
COMMERCIAL AUTOMOBILES

Alco, Autocar, Brush, Buick, Butler, Buffalo, Chase, Couple-Gear, Electric Commercial, Fuller, Frayer-Miller, Gramm, Garford, Grabowsky, General Vehicle, Hart-Kraft, Knox, Martin, Morgan, Pope-Hartford, Randolph, Rapid, Reliance, Studebaker, Sampson, and White.

In addition to the automobiles as above enumerated, there were twelve makes of motor cycles on exhibition, as follows: American Simplex, American, Crouch, Emblem, Excelsior, Indian, Merkel, Light, Pierce, Racycle, Reading Standard, Thor and Yale.

Marmon Exhibit Included Various Types of Torpedo, Touring Car and Roadster

In the Main Hall, Pierce-Arrow Exhibited a Chassis, besides Complete Cars



Attractive Maxwell in Pure White with Striping and Seat Covers in Soft Gray

Around the Galleries, Where Many Tire Manufacturers Exhibited; Foreground Occupied by Bragg

Accessories Occupy a Prominent Place

THE statistics of the automobile industry, excepting in a limited way, have been compiled with a view to picturing the automobiles complete, and little has been said about the accessory makers, who depend upon the automobile proper for returns. The makers number slightly under 300, not counting a hundred or more embryo propositions. Neglecting the embryos it may be stated that the 300 makers of cars on a more or less large scale support accessory companies about as follows:

ACCESSORY MAKERS SUPPORTED BY AUTOMOBILES

Tops, 140; Spark Plugs, 133; Aluminum and Brass Castings, 160; Bodies, 172; Axles, 55; Ball and Roller Bearings, 152; Brake Linings, 24; Batteries (dry), 61; Batteries (storage), 104; Bumpers, 22; Carburetors, 84; Chains (sprocket), 11; Non-skid Chains, 24; Clutches, 30; Spark Coils, 52; Commutators, 14; Crankshafts, 35; Dashboards, 40; Fans, 20; Carburetor Parts, 12; Drop Forgings, 98; Frames (chassis), 14; Gear Blanks and like parts, 35; Transmission Systems, 72; Mudguards, Aprons, etc., 60; Tire Holders, 52; Lamps (gas), 36; Lamps (oil), 28; Lamps (electric), 12; Mechanical Oilers, 18; Magnetos (some imported), 63; Motors, 80; Mufflers, 32; Foot Pedals and like parts, 19; Radiators, 32; Suspension Springs, 45; Valves and Mechanism, 42; Road Wheels (wood), 24.

The above list is an approximation which does not include a great many manufacturers in a small way who confine their efforts to work which is farmed out. It would be impossible to state the percentage of the total work which is accomplished by the farming process and which keeps many small shops constantly engaged, but it might be reasonable to assume that 20 per cent of all the accessory work is done in this way. It is all accomplished by sub-contractors who do not resort to publicity.

BOSTON and its encircling cities and suburbs produce many articles which the automobilist uses daily. True, the Hub was never named with regard to the automobile industry, and to many it may seem strange to think of the city of culture as a center of busy factories and salesrooms. The visitor will soon learn his mistake. Automobile row, on Boylston street, will not suffer by comparison with the other automobile rows on Broadway and Michigan avenue; and in the number and importance of its manufacturing plants the Bay State capital assumes a high rank.

Twenty minutes' ride by trolley from Mechanics Hall, in Cambridgeport, is the plant of the Dover Stamping & Manufacturing Company, from which come funnels, oil cans, tanks, drip pans and many other manufactures of sheet metal. Every housewife knows the Dover egg beater, and the Dover line of automobile accessories is almost as proverbial in its excellence.

Back in 1833 the Dover Stamping & Manufacturing Company was first organized in Dover, N. H., taking its name from its native town. Successive enlargements finally ended in the establishment of the present plant in Cambridgeport, on Putnam avenue. It occupies a group of seven buildings. The largest, which houses most of the heavy machinery, is a three-story brick structure 43 by 155 feet, standing on the corner of the block. Extending in line with this are two other frame buildings, one of two stories, 40 by 125 feet, and one of one story, 32 by 82 feet, used for galvanizing. At the side of the main building is the office, and in the angle thus formed is the power plant, 45 by 42 feet; a brick tinning room, 61 by 31 feet; a three-story brick forge shop, 73 by 30 feet, and stables and sheds.

On the first floor of the main building are several presses, each approaching 15 tons in weight, for drawing sheet metal into various forms. These are capable of shaping a bowl two feet in diameter and eight or ten inches deep out of a single piece of flat sheet metal, the resulting product being without seam and smooth and flawless in its texture. Here, too, are a half-ton drop hammer for stamping out parts which in general contour are flat, and a multitude of cutting dies for those articles which must be built up of several pieces.

The roughly formed parts are taken from their dies and presses to the assembling room on the second floor. Many ingenious machines form the equipment of this room. There is a seamer which will take the stamped-out bottom piece of a gasoline pail or a graduated can and apply it to the body of the vessel far more quickly and neatly than the most skilled hand worker. Another binds the stiffening wires around the tops of pails and funnels, and turns the sheet metal back smoothly over them.

Monarch Shock Absorber Applied to a Packard Car

Other machines, resembling ordinary lathes, but with blunted tools, true up the cylindrical and conical parts. Finally the pails and funnels are taken to the finishing room to have their handles and spouts applied.

Although the product of the Dover works, as intimated above, is by no means confined to automobile accessories, the attention which the company is paying to this end of its line may well be demonstrated by the ingenuity and novelty of the articles for automobile use. Pails and funnels in themselves are simple things, but the Dover company has a combined pail and funnel which does away with one pouring of the gasoline. It is a funnel provided with an automatic valve, which is normally closed, but opens when the funnel is set into the filling hole of the tank. A ball, which seats in the bottom of the funnel, with a stem projecting through the nozzle, and a spider on the end of the stem, with arms bent back over the outside of the nozzle, so that the funnel rests on them while in the filling hole—these do the trick. Incidentally, they provide an air vent, and so still further facilitate filling.

For garage use there are funnels of a bowl-like shape, a foot or more in diameter, and holding a couple of gallons. Their particular beauty is that the chamois strainer in the bottom is the full diameter of the bowl, and as the speed with which a tank can be filled depends usually on the rate the gasoline strains

Inspecting Room of the Hopewell Brothers' Factory at Newton, Where Hopewell Tire Covers Are Made

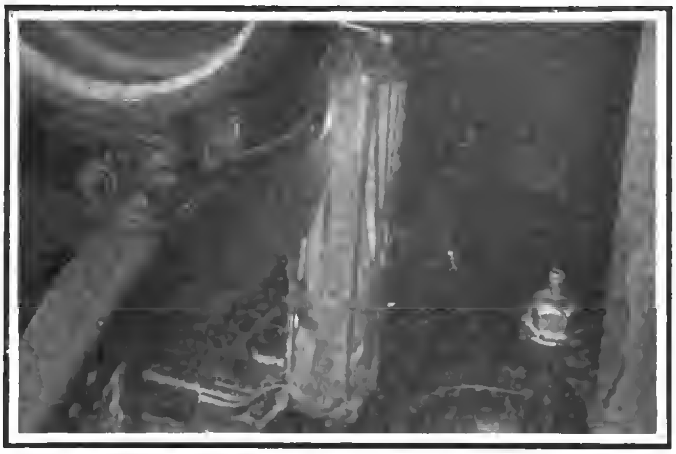
After 65,000 Miles on Flentje Shock Absorbers

through the chamois, time is economized still further. Space does not permit description of the many other funnels, gasoline cans, oilers and such articles from the Dover plant, save only an offset funnel which will be found useful on many cars with gasoline tanks hung from the frame in the rear. For the rest, the automobilist may be assured that anything else in this line can be had with the Dover trademark.

Turn now to another article of an importance best realized when a tire bursts miles from a garage—as tires still will do. When this misfortune befalls, lucky is the automobilist who has carried his spare shoe in a waterproof case, and so has it firm and sound to take the place of the one that has failed. Tire cases, and especially waterproof ones, are the province of Hopewell Brothers, who have just moved into the new factory in Newton, which they occupy in conjunction with L. C. Chase & Company's robe manufacturing department.

In the equipment of this new brick building no trouble was spared to secure the most modern tools and appliances. Electricity is used throughout, both for lighting and as motive power. One ingenious application of the electric current is found in the knives by which the fabric for the tire cases is cut according to pattern. These work vertically, being reciprocated by the little motor on top of the device; under the guiding hand of their operators they eat their way through 40 thicknesses of the heavy coated fabric as easily as a tailor cuts his cloth. The fabric comes in such lengths that five of the circular halves can be cut from each piece, and as 40 pieces are cut at once by a single movement of the knife, that means 200 halves, or 100 complete cases.

A whole battery of sewing machines is employed to sew together the halves and hem their edges with the endless coil springs in place in each hem. These springs are the feature of the Hopewell case which makes it waterproof. It will be understood that the finished case is but a single piece, without straps or flaps; it is simply a cylindrical piece of fabric with a slender coil spring on each edge tending to draw it into the annular shape of a tire. When it is wrapped around a tire, the coil springs draw the fabric down on all sides with an even tension, smoothing out all wrinkles and making their overlap waterproof.



How the Kilgore Shock Absorber Looks on a Matheson

Springs for these cases are quite an item in themselves. These are about a quarter of an inch in diameter, and of lengths suitable to the size of the tire which the case is to fit. The springs for each case weigh about half a pound, and some idea of the quantity of the output can be gained from the fact that 2,500 pounds of springs are used in a week. Half a mile of fabric is cut up in the course of a normal working day.

After the cases are finished they pass through a rigid inspection, both for finish and for dimensions. In cutting the fabric, the pattern is followed within an eighth of an inch. The case, after being sewn up, must be within a quarter of an inch of the correct circumferential length. Slight errors, of course, are taken up naturally by the springs; and besides, the dimensions of

Shawmut Tires, Both Shoes and Inner Tubes, Undergo a Rigid Inspection Before Leaving the Factory

Finishing Room of the Dover Plant, Where Spouts and Handles Are Fitted to the Buckets and Funnels

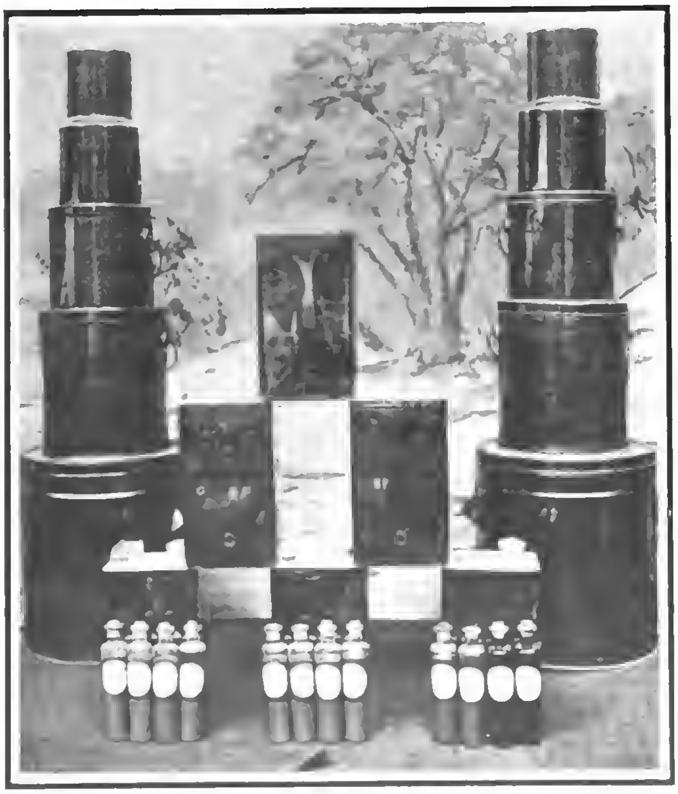
the tire cannot always be depended on for extreme accuracy. Patterns in most cases are based on the sizes of the standard rims, but many special cases are met with, especially since the vogue of the demountable rim. One of the latest products of the Hopewell factory is a cover to fit a Stepney spare rim and tire, with the clamping bolts all in place.

Business in Hopewell tire cases showed last year an increase of 250 per cent. over the year preceding, and the first two months of 1910 have yielded another 50 per cent. on the final figures for 1909. The capacity of the new factory, with its present equipment, is 50,000 cases a year, but arrangements have been made to triple this, increasing by degrees as necessary without disturbing the daily routine. For instance, the sewing machines are arranged in groups of five, mounted on a single table with an electric motor to drive them, and the groups can be moved around to suit the needs of the moment.

From tire cases it is a natural step to tires, and from the Hopewell factory in Newton it is but a short journey to the home of the Shawmut tire, in Watertown. The Shawmut Tire Company occupies a part of the enormous plant of the Hood Rubber Company, whose product is world-wide in its use. The advantages of the arrangement are obvious.

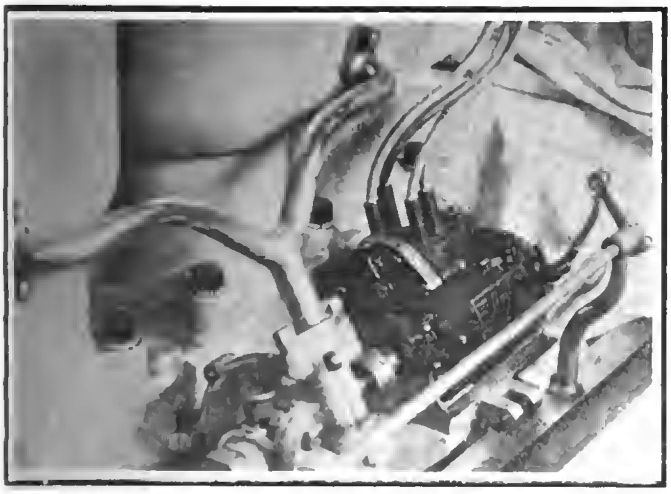
The manufacture of a tire is one of the most interesting processes in the automobile industry. The first wonder is that it is possible to make a slender bandage of a vegetable gum, inflated with air, which will support a two-ton mass of steel moving at velocities of a mile, or two miles, a minute. In the Shawmut factory each step of the process may be followed. The base on which the tire is molded is a heavy ring or core of cast iron, shaped to the proper size for the interior of the shoe. For the workman's convenience this is mounted on a hub with three adjustable spokes, which may be screwed out until they clamp it firmly. On this as a foundation the carcass is built up with successive layers of rubber and fabric, each rolled down until it becomes an integral part of those underneath.

The next step of the process is the vulcanizing. For this the carcass is put in a cast-iron mold, covering it completely, and with a number of other carcasses in similar condition is placed in an oven, carefully heated by steam to the desired temperature. This is the most lengthy process, as the heating lasts for six hours.

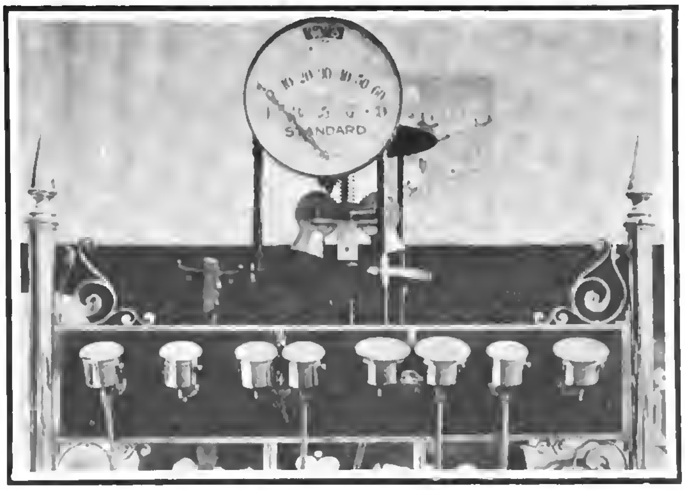


Motorol's Show Exhibit against an Artistic Background

Harris Oils Had a Comprehensive Exhibit at the Show



Mea Magneto, a New England Product, on a Parker Motor



Show Exhibit of Standard Speedometers Was Interesting

From the vulcanizing ovens the carcass is again taken to the workbench to have its tread wrapped on. This is of a grade of rubber differing greatly from that which forms the carcass; whereas the latter is compounded for resilience, the tread is compounded for toughness and wearing qualities. This tread layer applied, a second plunge into the oven gives the final cure. For this the tire, now complete, is wrapped in coarse sacking and exposed in live steam under the proper conditions of temperature and pressure. Metal molds, if used in this last operation, would be likely to burn the rubber; hence the exposure to the steam direct.

The equipment of the Shawmut plant comprises a number of ovens, of both the horizontal and the vertical types, and ranging in capacity from seven to twenty-five tires at one loading. Overhead trolleys are provided for handling, this being especially necessary for the first vulcanizing, in which the molds are used, as the weight of the molds ranges from 1,000 to 1,400 pounds.

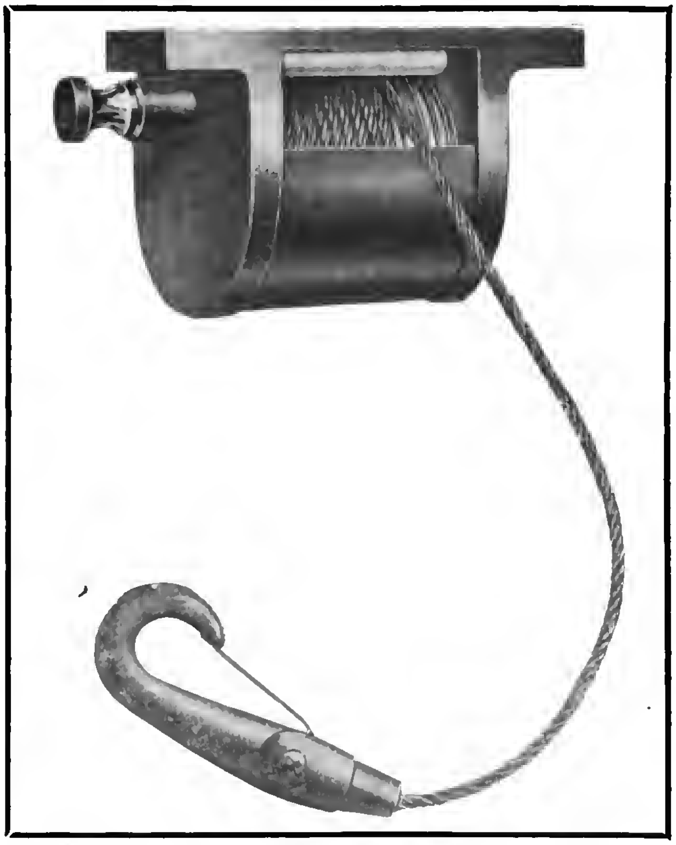
Shawmut tires are now entering upon their third season on the market. The growth of the company and the increase in the quantity of its product has been normal, though rapid. At present the capacity is 100 tires a day; although this does not entitle it to a rank among the giants of the industry, it is no small figure, as it means a total value of output of $1,000,000 a year. In addition to its separate equipment for such processes as concern tire making exclusively, the Shawmut company has all the facilities of the Hood Rubber Co. in the production of raw materials.

Within a few blocks of Harvard University, in Cambridge, Ernst Flentje has located the machine shop in which he makes the Flentje "shock preventer." His invention was the outgrowth of tests and experiments made with the idea of improving the riding qualities of his car, which he found very uncomfortable on rough roads. At the time he had no intention of putting the device on the market, but at the solicitation of friends who had ridden in his car he made and attached a number of sets. He finally undertook to manufacture them in quantities and offer them for sale, and patented the device in September, 1908.

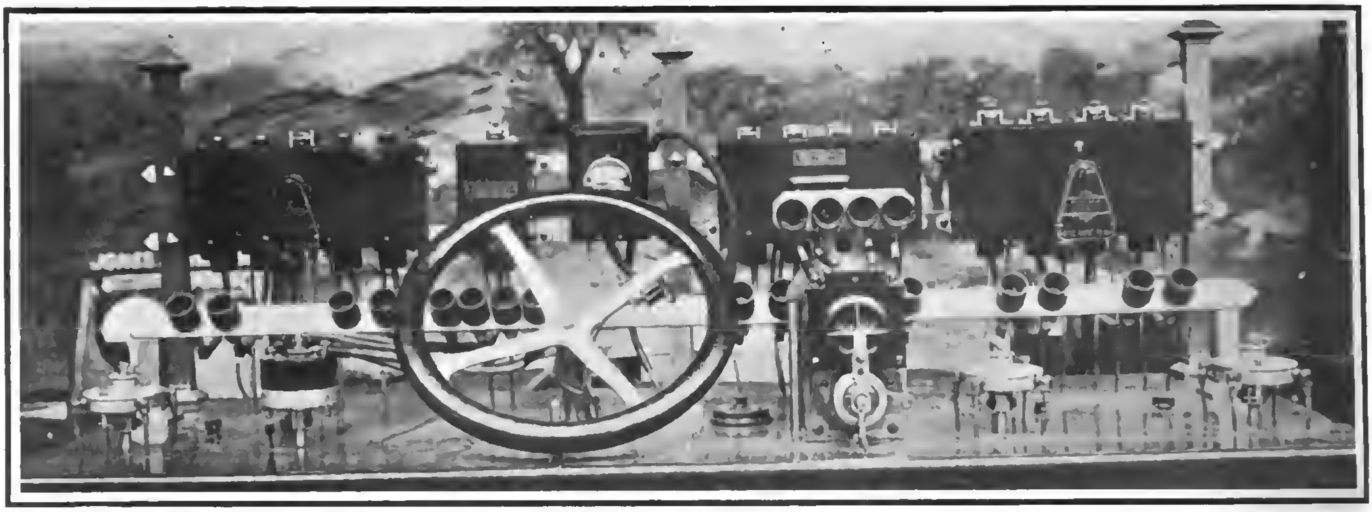
The principle on which the Flentje shock absorber works is familiar to all. It is, generally speaking, a hydraulic device; the liquid used is glycerine. A cylinder, filled with glycerine, is attached to the axle of the car, at each spring seat; in the cylinder works a piston, with suitable perforations for the passage of the glycerine from one side to the other. The piston rod is attached to the frame of the car. Both cylinder and piston rod are, of course, attached in such manner as to allow the sidewise movement due to the swaying of the car body.

Any vertical movement of the car body and frame relative to the axles must result in a movement of the piston within the cylinder, and the consequent passage of glycerine from one side

At the Show; the United Manufacturers' Varied Exhibit



Emil Grossman's Spring-Actuated Reel for Top Cables



Connecticut Electric Company, from Meriden, Conn., Had a Good Exhibit of its Ignition Appliances

of the piston to the other. As glycerine is practically non-compressible, the movement is limited by the rate of its passage through the perforations in the piston. The proper size of the perforations can be determined once for all for a given car.

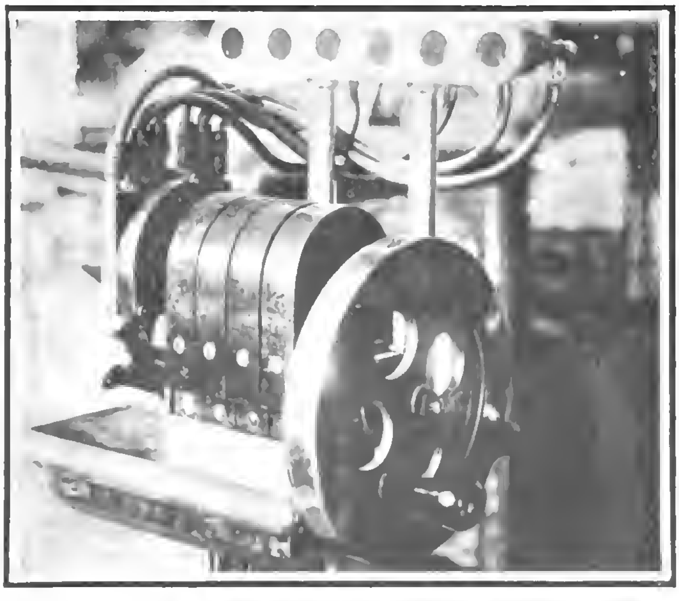
For the manufacture of these shock absorbers Mr. Flentje built a good-sized machine shop in the rear of his Cambridge residence, but the growth of the business has since forced him to have a large part of the machine work done in another Cambridge shop, where good facilities have been secured. The home shop does the lighter work, including the assembling, the insertion of the piston-pin packing, the finishing and final inspection. The construction is solid and substantial; the cylinder and end pieces are of bronze, and the piston and rods of steel.

Doctors are generally supposed not to like their own medicine; but the saying does not apply to this case. Mr. Flentje's own car, which has a record of 65,000 miles, witnesses the fact that this inventor uses his own invention and enjoys it.

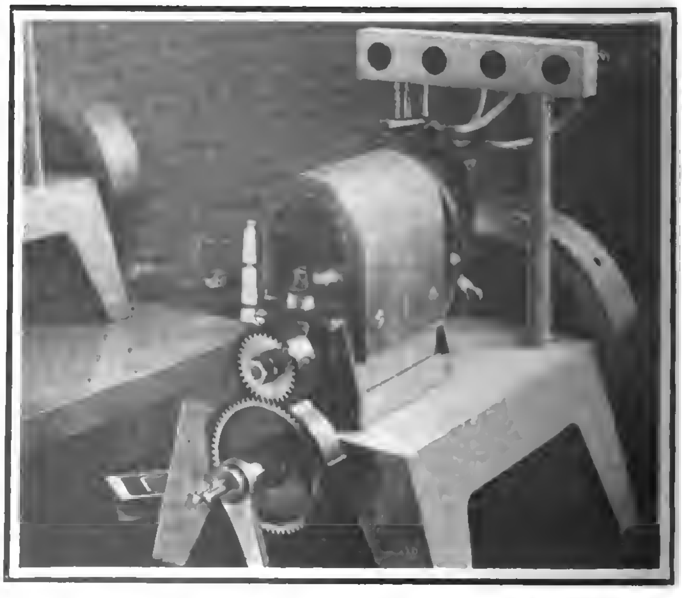
The Hoffecker Company, manufacturer of the speedometers with the "steady hand," has a commodious shop in the Motor Mart, a large building on Park square, Boston, exclusively devoted to the various industries connected with the automobile. The company has its offices and a large machine shop on the second floor, and an assembling and inspection room on the third floor. The machine shop is well equipped with the necessary drill presses and lathes; these are mostly light tools, as the work on the small speedometer parts resembles closely the operations of watch making. An exception, however, is a 6500-pound punch used for stamping out the top plates complete, with all perforations and bearing seats. This results in a great economy of labor and expense, as compared with hand work, and the finished product has the additional merit of being exactly to size and interchangeable.

The assembling department has a light and airy room, adapted to securing the best results in the way of careful and conscientious work. Micrometers are much in evidence here, showing the accuracy with which the parts are fitted. Highly skilled workmen are employed for this, and the analogy to clock-making is carried still further. When the instruments are assembled the dial is put on and calibrated by hand, each instrument separately, so that all are absolutely correct in their readings. After the case is put on and the final finishing done, another test is made before the instrument is allowed to pass to the sales department.

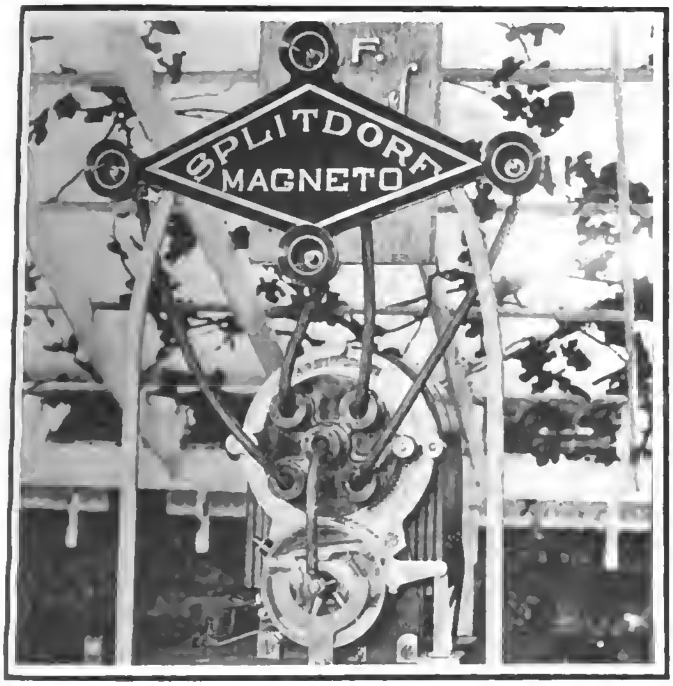
All Hoffecker speedometers operate according to the principle of centrifugal force, in the same way that the speed of a stationary steam engine is regulated. The front wheel of the car, through a flexible shaft, drives the "expander," a miniature ball-type governor. The indicating hand is absolutely controlled by this governor, which is built on correst principles, perfectly balanced and running on ball bearings. The special feature of the Hoffecker, however, which is covered by exclusive patents, is the lever connection between the governor and the indicating



Eisemann Magneto Exhibit for Hand-Power Demonstration



Bosch Exhibit Was Interesting to All Who Passed By



Ingenious Working Exhibit of the Splitdorf Magneto

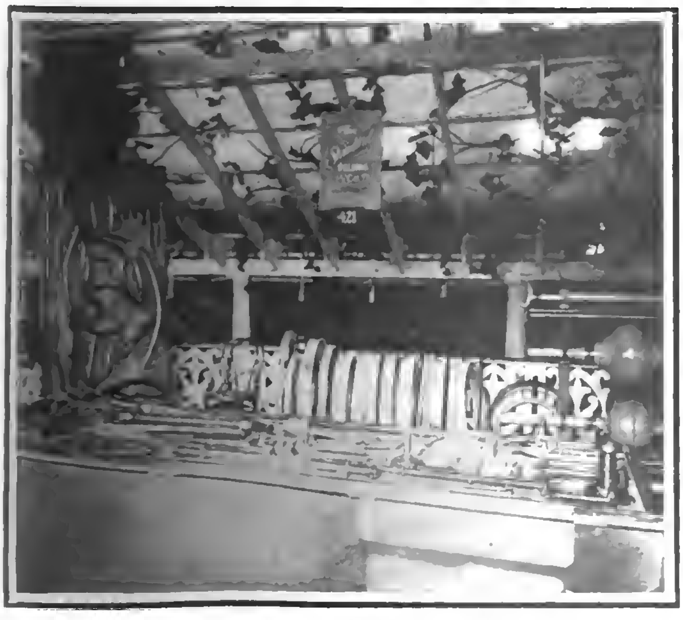
Pyramid of Hoffecker Speedometers of the "Steady Hand"

hand. The connection is controlled and interrupted by these levers in such a manner as to prevent the vacillation of the hand from any cause other than an actual change in the speed.

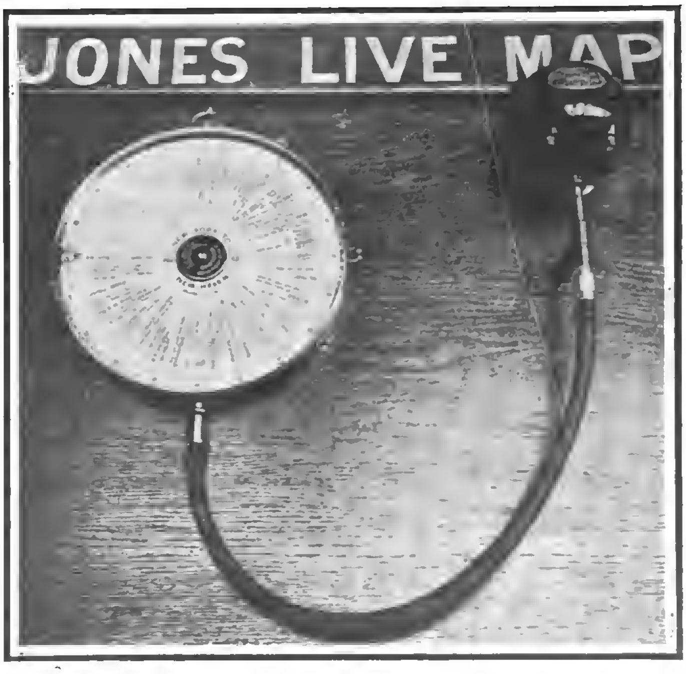
Hoffecker speedometers have a distinctive appearance, being cylindrical in shape and set with the dial end up, the fixture attaching them to the dashboard being arranged so as to give them an angle convenient for reading from the seat. The flexible shaft is connected through bevel gears at one side. The dial has another distinctive feature, in that the odometer trip mileage is indicated by a hand moving over a circular scale, concentric with the speedometer scale.

Another shop located in Boston proper, the product of which is familiar to most automobilists, is that of the Kilgore Mfg. Co., at 9 George street. Here the Kilgore pneumatic shock absorbers are made. A complete equipment of machine tools permits the manufacture of all the parts entering into this device. The materials used are Government specification bronze, for the cylinder and piston; cold-drawn seamless brass tubing, for the outer shell or mud shield, and tool steel castings for the brackets and clamps.

The operation of the Kilgore device depends on the elasticity of the air with which the cylinder is filled. The cylinder, to start with, is attached to the axle, and the piston to the frame of the car. The piston is solid, without holes opening from one side to the other. Were this all, a progressively increasing resistance would be secured to any movement of the spring in either direction. But such a resistance is not desired; what is really wanted is to leave the spring movement free for a considerable distance up and down, before the resistance is added. For this purpose a by-pass passage is provided in the cylinder wall which allows the air to move from one side to the other with considerable freedom when the piston is near the center of the cylinder; but a further movement of the piston covers up the opening, and the air thus entrapped between the piston and the upper or lower cylinder head, as the case may be, is compressed until the movement is checked. The by-pass is adjustable for area, and as it is quite small in proportion to the cylinder area, a considerable resistance is still interposed to any



Standard Welding Company Showed Axle Casings and Rims



Jones "Live-Map" Was a Drawing Card, As Often Before

Lancia Steering Wheel showing a rotary star shaped member concentric with one of the arms adjacent to the rim by means of which the mixture is adjusted to suit the requirements—ignition is fixed and requires no controlling lever

too rapid movement of the piston, even when near the center. A very good feature of the Kilgore is the double protection afforded against dust. The piston rod, besides being provided with the usual packing, is enclosed in a flexible leather boot, like that used on the drive shaft universal joints; and outside of this is a light brass shell which slides over the outside of the cylinder, and is provided with another packing ring.

Above the machine shop floor of the Kilgore factory are the assembling room and stock room. The shock absorbers are made in three sizes, the 2½-inch (cylinder diameter) for cars weighing not over 2,000 pounds; the 3-inch for cars weighing up to 3,000, and the 3½-inch, for very heavy cars. Thus a considerable number of parts must be kept in stock. The company had a very handsome exhibit at the Boston show, the feature of which was a stand hung with the different sizes of shock absorbers in polished brass, against a background of maroon.

For some unknown reason no dry-cell factory had been established in New England until the Universal Carbon Company brought out the "Diamo" brand, and built its factory at Ashland. This new plant has 120,000 square feet of floor space, and a modern equipment of machinery. Contrary to the usual practice, which calls for a large amount of hand work, the "Diamo" cells are made almost entirely by machinery, this being necessarily of several special designs. In this way uniformity and reliability are guaranteed.

Great care is taken to secure the best of material for the cells, and careful analysis is made of all, to secure them as nearly as practicable chemically pure. One test made quite recently by the Massachusetts Institute of Technology on the carbon used revealed that it was practically pure carbon; on ignition it left a residue of 0.10 per cent, consisting of silicia and traces of iron. In other words, the carbon was 99.9 per cent pure.

Casgrain speedometers, another distinctively New England product, have their inception in the factory of the Couch & Seeley Company, at 10 Thacher street, within a few blocks of the North Station in downtown Boston. Much stress is laid on the length of the scale of these speedometers, being no less than 28 inches, and on the fact that there is an individual number on the scale for each successive mile per hour, from 1 to 65. The instruments are calibrated and the numbers applied by hand, and the calibrating stand is a most interesting feature.

An electric motor drives through friction wheels a shaft which in turn drives six speedometers. The friction wheels are similar in arrangement to those used for changing the gear ratio on several well known makes of automobiles; one large face wheel is on the motor shaft, and a smaller wheel is mounted on the side shaft with its periphery against the face of the other, in such a manner that it may be slid back and forth to vary the speed of the side shaft. Of the six speedometers driven from the side shaft one is the master instrument, calibrated originally from a tachometer.

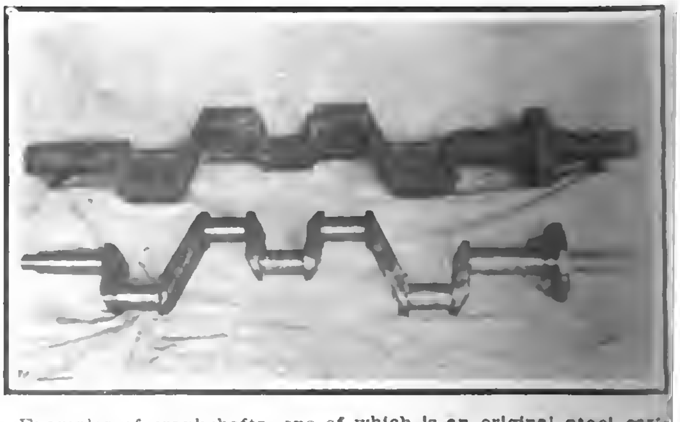
Given this equipment, the process of calibrating becomes very simple. The man in charge adjusts the driven friction wheel to a position quite near the center of the driver, to give a low rate of speed, until the master instrument reads one mile an hour. All the other speedometers are then turning at exactly the same speed, and the figure 1 is affixed to their scales at the spot indicated by the pointers of the instrument. Then the driven friction wheel is moved out a little further until the master speedometer reads two miles an hour, and the figure 2 is affixed to the scales of the other five. The process is continued for every figure up to 65, which is as high as the standard Casgrain reads. The figures are about ⅜-inch high.

Naturally it is a matter of interest how the makers of the Casgrain are able to obtain room for such a scale on an instrument of any reasonable dimensions. The answer is that the figures are placed spirally around a cylinder, which moves to correspond with the speed and brings the figures in succession before a window in the outer case of the instrument. The row of figures encircles the cylinder four times, and a brief calculation will show that the diameter of the cylinder itself, for a 28-inch scale, need be only a little over 2 inches.

The cylinder bearing the figures is rotated by liquid friction. Inside of it turns a shaft with paddle wheels, which carry along with them the liquid with which the case is filled. The cylinder has no direct mechanical connection with the shaft or paddles, but is turned by the friction of the liquid against its inner surface, against the tension of a spring. The force exerted by the friction is of course proportional to the speed of the inner shaft, which is driven by the usual connection with the front wheels. The design is such that there is not the slightest possibility of any of the liquid leaking out or evaporating.

Oil guns, grease guns and gasoline tank gauges, in addition to the "Jericho" horn, come from the Randall-Faichney Company's factory at 251 Causeway street. The latter differs from most exhaust horns in that it is always attached to the rear of the muffler, on the end of the exhaust outlet, and so its application does not require cutting the pipe. The horns simply clamps on, and ordinarily does not obstruct the free passage of the exhaust gases. When a hay wagon obstructs the road, however, the driver simply presses a pedal, which closes up the main outlet and diverts the gas through the horn, with effective results.

Another Randall-Faichney product is the "Webster" gauge, a float-operated device. The float is attached to a horizontal shaft, which turns the vertical indicating shaft by means of a



Examples of crankshafts, one of which is an original steel casting, the other being a finished crankshaft. This illustration is offered to indicate the advances which are being made in steel casting work, although there must be a speculative condition crown gear and pinion. The gauge is attached without soldering, and may be done without emptying the gasoline from the tank. The line of "B-rail" oil guns is too well known for comment.

The "Monarch" shock absorber depends for its absorbing and checking action on the pressure of a heavy coil spring against a cam which is rotated by any movement of the car frame relative to the axle. The cam is mounted on the frame, and is connected to the axle by a crank and connecting rod. A hardened steel plunger, backed by the coil spring, bears against the face of the cam. On that part of its face which the plunger bears against when the springs are in normal action, the cam is perfectly round, and so no resistance is offered to any movement of the springs a slight distance either side of center. A continued movement, however, brings the cam into action on the coil spring.

When the springs are in normal condition, the crank is horizontal, and so the axle has the greater leverage against the spring; but as the car moves up or down, its leverage decreases, until finally, in the case of a very violent shock, the crank is on dead center, and so brings the spring movement to an absolute stop. It is claimed to be impossible to break any spring fitted with this shock absorber. Charles M. Green, at 1036 Old South Building, Boston, acts as general distributor.

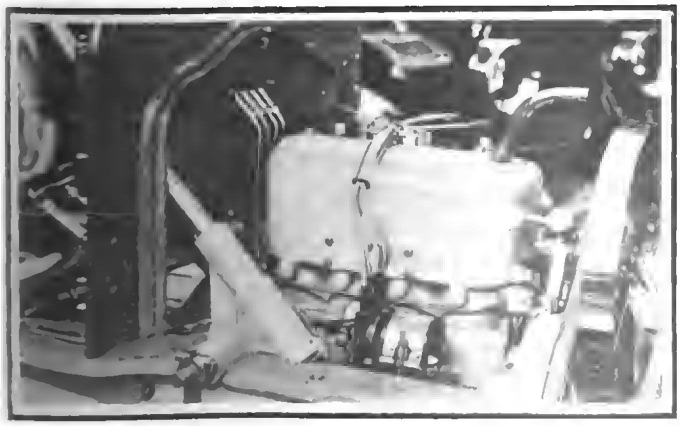
A gasoline tank gauge which works by magnetism is made by the Boston Auto Gage Company, at 8 Waltham street, under the trade name of the "Triumph." The noteworthy feature is the absence of any opening between the inside and outside part of the gauge. There is a vertical brass tube inside the tank, with a metal float inside which works in a spiral slot in such manner that it must revolve as it moves up and down with the varying level of the fuel. The indicating part of the gauge is entirely separate. Magnetism makes the connection between the two. If the glass over the indicating hand and scale should be broken, there still could be no escape of gasoline or air pressure.

White foot pedals showing the means of adjustment whereby the operator is enabled to lengthen the pedal stems to suit his own individual requirements; also the accelerator pedal and the connections of the Bosch dual ignition system

Some Features the Camera Caught at Boston

NOVELTIES at Boston were no fewer or less important than at the New York shows. New England is well recognized as the home of inventors, and new ideas keep cropping up there quite frequently. What was perhaps the most important new development was not a product of New, but of Old England.

After several years' absence from the American market, the Napiers made famous by S. F. Edge, the world's champion publicity man, bowed anew to the Boston enthusiasts. The famous English firm is now represented in Boston, for the United States, by British Napier Motors, Inc., at 47 Union avenue, Jamaica Plain. These cars were the first to adopt the six-cylinder motor, but after using this type exclusively for a time, found it necessary to bring out two- and four-cylinder models in order to cover the whole field. The Napier line now consists of a 10-horsepower, two-cylinder, a 15-horsepower, four-cylinder, and six-cylinder cars of 30, 45, 60, and 65 horsepower.



White Steamer showing the right side of the motor of the block type, nesting of the magneto, adjustable fan bearings, and the location of the steering gear housing with the arm passing above the chassis frame

The two- and four-cylinder cars are especially adapted for town work. They have the unit form of construction, the gear case surrounding the clutch and bolting to the rear end of the crankcase. The flywheel is placed in front. Cylinders are cast in pairs, with all valves on the left side. The distinctive Napier hood and radiator, the latter with its long tubular filling cap, are found on these small cars as well as on the sixes.

The 15-horsepower model finds extensive use in London as a taxicab, being found very satisfactory and economical in this service. This chassis, as well as the two-cylinder, also makes a good light delivery wagon.

A prominent feature, and one which quickly caught the eye of the visitor as he entered the show, was the new Herring-Burgess aeroplane hanging from the ceiling. This air-craft is the design of A. M. Herring, formerly the partner of Glenn Curtiss, and was built by W. Starling Burgess, the yacht-builder of Marblehead, Mass. In its detail it shows the effect of the mariner's training and instinct, being far superior to the majority of aeroplanes. This aeroplane also has the distinction of being the first to fly in New England.

This flight was made at Hamilton, February 28. It was regarded as of great importance because it constituted the first trial of Mr. Herring's device for insuring automatic stability. The start was not attempted until late in the afternoon, owing to the rain and wind. About 5 o'clock, after a short preliminary run of about 90 feet, equaling the world's record in this respect, the 'plane shot into the air. After rising to a height of 40 feet and turning through an arc of about 45 degrees, Mr. Herring, who was acting as aviator, shut off the power, and the machine glided gracefully to the ground, after covering a distance of about 120 yards.

Mr. Herring said that he was more than pleased with the result, not having intended to go so far on his first trip. When he once got into the air, however, he found it so easy that he kept on going up.

Stearns presenting details of the anchorage of the torsion tube to the cross member, presenting a large spherical bearing, universal action and the method of spanning the universal joint, which results in double bearings symmetrically disposed

The machine is a biplane, and is fitted with a Herring-Curtiss four-cylinder motor of 25 horsepower, with a four-bladed propeller on the rear end of the crankshaft. The automatic stability device consists of a number of small triangular surfaces like leg-o'-mutton sails, extending vertically from the upper plane. When the machine tips to either side these exert a righting effect. Each of them has a surface of about two square feet, and they are six in number, four being placed close together over the middle panel of the machine, and the other two about half way out to either end. The machine is mounted on three skids, one long one under the middle and two short spurs, one on each side.

Morse Car the Newcomer

The list of exhibitors promised two new cars, one of which was to be the Anderson, but through some inadvertence it failed to develop on time, and section No. 133 was pretty well filled up with Kline Kars instead. The Morse car, however, which is made by the Easton Machine Company, South Easton, Mass., was in place, and is attracting a wide amount of discriminating attention which cannot be explained away on the ground that the car is new. The photograph of this car, which will be found among the especially noted features of the show, presents a chassis in the foreground, which has all the earmarks of satisfying quality. A glance at the chassis will show an I-section front axle, which curves downwards sufficiently to afford clearance, but the shape is such that strains do not accumulate at points of divergence. The front of the radiator presents a graceful appearance, and cooling is due to the use of this radiator, which is the honeycomb type, and a centrifugal type of relatively great capacity, which is securely bolted into place, is driven by a safety dog, and has a packed gland. The motor is of the 4-cylinder, water-cooled type with valves in the head, individual cylinder castings, flanged and bolted to a crankcase, which is of cast aluminum with four integral arms, and the dust protecting flange system all arranged to support the motor between the side bars of the chassis frame. The oil sump in the bottom half of the crankcase is flanged thereto, and by unbolting this bottom half, it is possible to inspect and clean the oiling system, also to take up on bearings, and if the occasion requires, the pistons and connecting rods may be removed, repaired and replaced. The Stromberg carbureter is fastened to an intake manifold which is noted for its perfectly symmetrical T shape, and is so sized that popping in the carburetor and other troublesome performances are eliminated. Ignition involves the use of

The Morse exhibit presenting a chassis in the foreground, flanked by a "gunboat" type of body to the right, and a conventional form of touring car in the background. The stand was well arranged to set forth the merits of the car

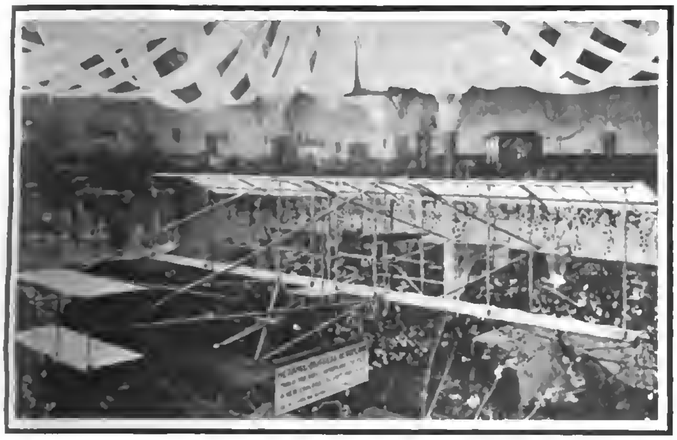
an Eisemann dual system, which, of course, includes a magneto and means whereby the ignition functions will be maintained even though the magneto may become deranged.

The crankshaft is of Krupp chrome nickel steel, forged under the hammer to give it its rough shape, and is then heat treated at the works of the Krupp Company at Essen, Germany, after which it is finished to exact size, which involves final grinding. The character of the material used in the crankshaft is reflected throughout the car. The clutch is of the multiple disc type, comprises 9 saw steel discs which are submerged in oil, and present 800 square inches of surface. A coil spring exerts the requisite pressure, and the foot pedal offers a lever advantage in the ratio of 6 to 1, so that disengagement is as easy as engagement is positive. A means for adjustment is provided, and a double universal joint counteracts torque inequalities, so that the clutch offers the advantage of utility and low maintenance.

The transmission is of the selective sliding gear type, with four speeds forward and one reverse. Three speeds ahead is on direct drive, through internal and external gear combinations, while the fourth speed is geared up so that on the fourth speed, the main shaft in transmission revolves faster than the crankshaft. Hess-Bright ball bearings are used throughout and all members including gears, pinions and shaft are made of heat-treated Krupp chrome nickel steel.

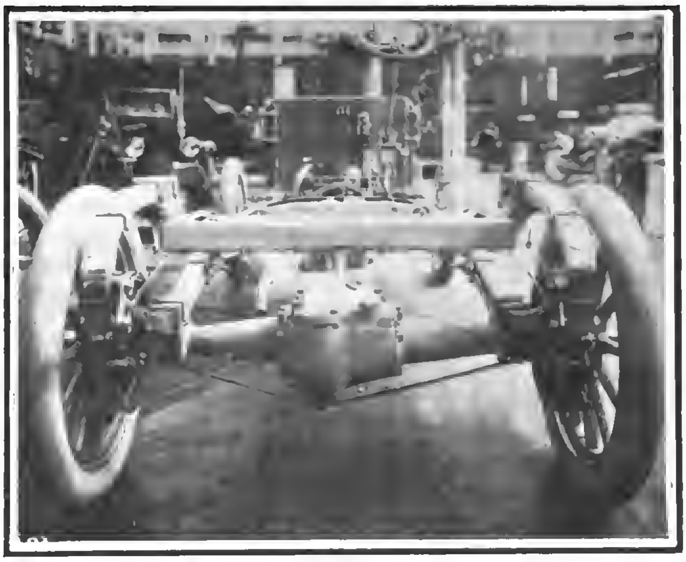
The steering gear is of the worm and sector type with a "Morse" cut. Every means is provided for adjustment, thrust ball bearings take the strains, and the housing is grease tight, with a means for feeding in grease as the occasion requires. The character of the workmanship throughout is consistent with the importance and nature of the service to be performed.

Rear view of the 15-30 Stearns, showing the kickup frame, substantial laterals at the rear, and a view of the live rear axle which permits the nesting of the differential gear, bevel drive, and transmission system within the branches of a special I-section axle



Herring-Burgess aeroplane, which was the first to fly in New England and is here presented as representing one of the fields of endeavor which was rendered possible by the perfection of the internal combustion type of motor for automobile work

The motor is rated at 24 horsepower, has a bore of 4 5/8 inches and a stroke of 5 inches. It is claimed that the power is actually realized at 800 revolutions per minute. The chassis frame is of the channel section, and in touring cars is 155 inches long. In the runabout type, however, it is reduced to 140 inches. The frame is so suspended with full elliptic rear springs, and half elliptic front springs, that it is 25 inches from the frame to the ground in front, and 27 1/2 inches between the same points at the rear. The wheels are 36 by 4 1/2 inches front and rear, with Goodrich tires on the touring car, and 36 by 4 inch all around, same make of tires, on the runabout. The live rear axle has a bevel reduction in the ratio of 14 to 47. The brakes are in 16 inch drums, with 2 1/4 inch shoe faces attached to the rear wheels, excepting the emergency brake which has an 11 inch drum located on the differential shaft. There are many other excellent features to be noted on this car, but they come as details, which are only to be expected, in view of the description already rendered, and will best find a place when the car is being written up.



White car showing the live rear axle with its bell shaped housing, smooth exterior, and method of bracing, also a spring perches double system of U bolts, three-quarter elliptic rear springs, and the method by which the springs are anchored to the chassis frame

The Morse line includes the standard type of touring car, and equipment, at $4,000, the runabout type at $3,900, and the chassis with a priming coat at $3,600, with options as to bodies.

RELATIONS OF PARTS MAKERS AND BUILDERS

By ALFRED REEVES, General Manager, Association of Licensed Automobile Manufacturers

THE already astonishing number of parts and accessory manufacturers who have been for some years co-operating in the production of motor cars is being added to at a remarkable rate. This is, of course, largely due to the reports that automobile builders cannot secure enough parts to make the output they have planned. Many old companies, notably those in the carriage trade, are making the change and becoming constitutent elements of the dominating motor industry. It is obvious that the closer these newcomers stick to their line of experience, the better co-ordinate units they will become in the industry.

I want to emphasize the point that the accessory and parts makers should put quality before everything else. There is nothing more important than quality, unless it be design. Poorly designed or made parts can have only the effect of discrediting their immediate producers, as well as the motor car makers who use them. The increasing importance of the interrelation between the parts makers and the car builders is a subject that can be profitably dwelt upon by anyone really interested in the industry. I have been gratified recently to note that parts makers are not only showing a tendency to stick to that line of manufacture in which they have had qualifying experience, but also instead of forcing production and taking orders beyond the point of possible delivery, disappointing everybody all along the line, are looking into credits and conditions carefully and acting conservatively generally; which action is viewed with marked approbation by automobile manufacturers. Nothing less than this is adequate in the proper and sound upbuilding of the industry, and, of course,, the conservation for all time begins with the steps taken in the upbuilding.

Alco, depicting the live rear axle, universal joint, pressed steel radius member, kickup chassis frame, half elliptic springs, and a commodious gasoline tank which is cut away to afford space for the enlargement of the axle to play in

Competition in the parts business must more or less soon become normal with profits reduced accordingly, success thereafter keeping step with inherent manufacturing and selling ability.

The modern automobile represents one of the highest achievements of mechanical engineering. No other industry probably has contributed so much to the development and refinement of machine tools, new, quick and accurate manufacturing methods, and of materials possessing enormous strength and properties undreamed of heretofore. Each and every part has been the constant subject of long and accurate tests and study, to bring about simplicity, strength and lightness, through proper distribution of material, according to mechanical laws.

This refinement is always going on, and no detail, however trifling, is overlooked in this steady march toward perfection. This is an index of the real task before the accesory and parts manufacturer, as well as the car builder; and indicates cl the field in which the manufacturers of merit will su

Exhibit of White Company

Broc Electric a newcomer

Elmore, Mitchell, Regal, Franklin-Overland occupied the center of Cleveland Show

CLEVELAND, Mar. 7—The Cleveland Automobile Club's show, the second for the city, opened Saturday night, and is generally conceded to have surpassed anything previously held here. Forty dealers are exhibiting cars, the total of makes represented being about seventy, and of complete cars there are over 160. So great was the demand for space that some of the exhibitors of automobiles were forced into the balcony, which has never been necessary before. The unfortunates number six. They console themselves, however, by the crowds which still penetrate to their stands.

A large crowd was waiting to enter the show when Mayor Baehr touched the button which turned on the illumination Saturday evening, and by 9 o'clock the big hall was filled to overflowing. The neatness and simplicity of the decorations excel anything yet seen in Cleveland. They are principally in white. The ceilings are concealed by five thousand yards of duck, and the walls and staircases are draped with bunting.

The balcony railing has been transformed into a solid bulwark of plaster of paris, ornamented at regular intervals with massive shields bearing each a lion's head and an automobile. The "automobile girl," the emblem of the show, stands in the very center of the hall on a high pedestal, resplendent with electric lights. From one end of the armory to the other strings of electric lights connect rows of Corinthian columns, all brilliantly illuminated. Suspended from the roof beams overhead are three clusters of lights, representing automobile wheels.

A prize of $100 has been offered for whoever recognizes the "Girl at the Wheel," after whom the central statue was modeled. The lady in question is said to be a prominent East End automobilist, and visits the show every evening, although not in the automobile costume in which she posed for the artist.

As in the earlier show, an extra aisle has been provided straight through the center of the hall. This arrangement has proved very useful in avoiding congestion, which otherwise

Sebring Another New One at Cleveland

Gunboat on Cadillac Chassis

Another View of Cleveland Shows Main Floor, Showing Beautiful Columns

would be extreme. Through this extra aisle the visitors were enabled to view the cars more quickly and so give the balconies a larger share of their attention.

Four companies which exhibited their cars in the earlier show also have spaces in the present one. They are the F. B. Stearns Company, the Studebaker Automobile Company, the White Company and Applebaum Brothers, who show the Detroit electric. The White Company did not decide to come in until the middle of the week and so had difficulty in securing place. When George Collister, the manager of the show, found that it was impossible to accommodate it otherwise, he asked some of the large exhibitors to spare a part of their allotments. This the C. B. Shanks Company did, and as a result the White Company has room to show two cars. The complete list of car exhibitors follows:

The Rambler Automobile Company, Rambler; the Babcock Electric Garage and Sales Company, Babcock electric; the Weddell House Garage, Inter-State and Holsman; the Studebaker Automobile Company, Studebaker; the Brandt Motor Car Company, Kissel-Kar; the Broc Carriage and Wagon Company, Broc electric; the Olds-Oakland Company, Oldsmobile and Oakland; the Maxwell-Briscoe Cleveland Company, Maxwell; the Charles B. Shanks Company, Chalmers and Hudson; the Cook Motor Sales Company, Premier and Reo; the Garford Motor Truck Company, Garford truck; the Sebring Motor Car Company, Sebring, O., Sebring; the Crest Motor Car Company, Paige-Detroit, Abbott-Detroit and Warren-Detroit; the Auto Shop Company, Thomas; the Western Reserve Motor Car Company, Pierce-Arrow, Apperson, Woods electric, Everitt and Hewitt truck; the Auto Sales Company, Velie and Hupmobile; the Euclid Auto Company, Firestone-Columbus, Columbus electric and Atlas; the Crawford Motor Company, Jackson, Fuller, Rider-Lewis and Stearns; the Buick Motor Company, Buick, Welch and Welch-Detroit; the Park Motor Car Company, Speedwell; H. S. White & Company, Pierce-Racine; the Overland Motor Car Company, Overland and Marion; the Regal Motor Sales Company, Regal; the Barger Automobile Company, Cadillac; Applebaum Brothers, Detroit electric; the White Company, White gasoline and steam; the H. H. Franklin Mfg. Company, Syracuse, N. Y., Franklin; the Mitchell Brothers Company, Ohio; the Elmore Motor Car Company, Elmore; J. H. Greenwald, Marmon and Moon; the Wentworth Motor Car Company, Mora; the V. R. Hall Auto Company, Cartercar and Plymouth truck; Lucas & Christenson, Mitchell; the Pullman Motor Car Company, Pullman; the Forest City Motor Car Company, Jewel; the Gabriel Carriage and Wagon Company, Gabriel, Krit and I. H. C.; Haynes Auto Agency, Haynes, and the Black Mfg. Company, Black-Crow.

The New York State Capital Made Its First Show as Impressive as Though It Were a Veteran at the Work

ALBANY, N. Y., Mar. 7—To make the first show ever held of such magnificence and attractiveness as to preemptorially challenge all others to the right of occupying first place in prominence is a big contract for any aggregation of men but such contract has been more than filled by the Albany dealers association in conjunction with the officers and men of the Tenth Regiment National Guard of New York located in Albany.

Buffalo, Rochester, Binghamton and New York City all had shows far in advance of all previous ones. They were all good and fine to look upon. But not one of them except Madison Square Garden presented anything like the spectacle that did this first Albany show. Of course both Buffalo and Rochester were bigger local shows but what Albany lacks in number of exhibitors she makes up in unobstructed floor space and harmonious decorative features.

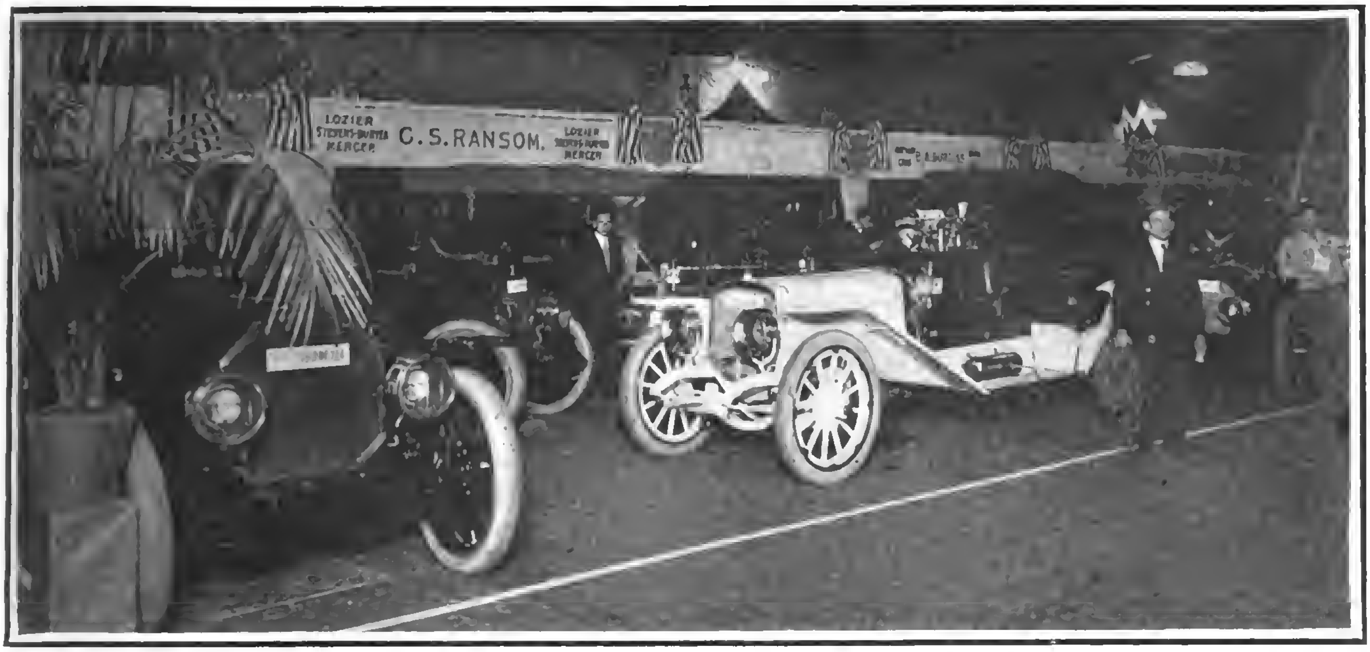
There are 35 exhibitors—all but six on the main floor. These 35 show 121 completed cars in addition to a long list of motors, chassis and accessories.

The armory in which the shows is being held, lacks but a few feet of being as large in floor area as is Madison Square Garden, that is, the main floor. This being true some idea may be gleaned of the splendid facilities for showing off all the cars. A vast crowd is almost lost among the exhibits.

The color scheme is as daring as it is beautiful. The dome and center ceiling is resplendent with national colors and flags. The side walls and balcony walls, to be found only at one end, are wrapped and artistically draped in a silken bunting of pale pink and white in wide strips. The idea of pink with the red of the national colors would seem to indicate a jarring effect but so skillfully has the work been done that this is far from true. Then, too, an abundance of stately palms and green ferns about the floors and suspended from the walls helps to harmonize the picture within itself. Suspended baskets of roses and other flowers illuminated by hidden electric lights added much to the general design. Down the center of the long drill hall is a partition or lattice work also wrapped and draped in white with big national shields separating the signs of the exhibitors. A profusion of palms and flowers furnishes the finishing touch.

The show is novel in several respects. The styles and designs of the cars are fine. They are more representative of the wide choice of the manufacturers than is usually to be found at a local show. Illustratively it should be noted that there are

Albany Tenth Regiment Armory Has Within a Few Feet of the Same Floor Area as Madison Square Garden



Comprehensive Exhibit of a Local Dealer, Including the Lozier, Stevens-Duryea and Mercer Cars

some seven or eight gunboat bodies, a lot of the ultra sporty runabouts, all in addition to a splendid showing of the standard designs. A glance at the list of exhibitors will also show that the very finest of American manufacture are to be seen here. Commercial wagons are also in evidence with five different makes shown on the floor.

Probably one of the most attractive exhibits is that of the Maxwell-Briscoe-Albany Company, showing seven Maxwells and two new Columbias. In addition to this line, which is the largest of any one make at the show, Manager Hadley has secured most of the Maxwell trophies and cups. These make a mighty showy case in the front of his space and are the center of considerable attraction.

Announcement was made at this booth that W. A. Hamilton, secretary-treasurer of the company, had recently been appointed manager of the Columbia department since it has been taken over by the United States Motor Company.

The Eureka Motor Car Company is newly organized by Charles A. Stiert and it is showing for the first time at any of the local shows in the State, the new Cutting car. It seems to have made a very favorable impression judging from reports.

The Buick exhibit which is also large in numbers is showing the Welch line, seldom seen at local shows.

A. J. Gervais, one of the late exhibitors, is showing "Brighten Up," a new non-acid, non-grease metal polish manufactured by S. C. Clapper & Co., at Nassau, New York.

The Walker non-skidding chain is also a newcomer in the field of accessories. The chain is said to prevent side skidding as well as slipping and spinning. The skid links are fastened at intervals in the center of the tire to a ring of the same metal as the chain and on the face look like really effective non-skids.

The management of this show is also varying from custom in that there will be no double admission society night. Upon Thursday night, however, a military night is planned, at which the brigadier-general and his staff will appear as a body.

It was expected that the governor might appear for the opening night but he did not and is looked for later in the week.

Turban of Feathers

AUTOMOBILE shows, which are held annually, arouse a wonderful amount of enthusiasm among the women motorists. They turn out in full force to view the new cars on exhibition, and their interest in motor matters is apparently as keen as that of their male escorts. In fact, the women who do not go to the show miss a good deal, and are counted out of the game by the women who do go. Many of the society leaders set the motor styles which the feminine portion of the world at large will follow, and many new motor fashions can be observed. Some of these motorists who have recently returned from abroad have brought back with them the very latest idea in motor garb from Paris, and their new coats, hats and veils bear the earmarks of the true Parisian.

Whenever two or three, or even more, of the fair sex are gathered together the motor car and the dress appropriate to the motor car are the chief topics of conversation. Motoring is now the leading sport for the up-to-date woman, and appropriate garb must be provided. There is now to be seen an enticing array of luxurious coats, coquettish hoods, becoming hats and attractive scarfs and veils which are built exclusively for motoring, and the woman who cannot make herself both comfortable and attractive in her motor togs has really to blame herself.

The fashionable motor coat is long and loose, and comes almost, if not entirely, to the hem of the gown. The heavy fur coats do duty when upon the road and are indispensable for the coldest weather. The leather coats are also garments of utility, but the cloth coats are most conspicuous for present wear, as well as the plaids and checks in the English blanket cloths and Scotch tweeds. The homespuns and meltons prevail with the best dressed women. The long, loosely fitting coats of breitschwanz are seen to a great extent, and will continue to be worn until really warm weather is at hand. The coat should have deep, roomy pockets and sleeves that come well down over the hand, and it should be cut in double-breasted fashion, with buttons all the way from the throat to the bottom of the skirt.

Fur-lined coats are usually made of broadcloth, melton or tweed, and have a big storm collar of a handsomer and more expensive pelt than is used for the lining. For driving or rainy days—and every true motor enthusiast defies the weather—there are long coats of gutta percha which have a high stand-up and turn-down collar and absolutely no opening. The coat stretches over the head and leaves one snug and dry, with absolute scorn for the falling rain. To accompany this coat is a very becoming little hood of waterproof silk, and with a rainproof chiffon veil the motor woman has no fear of the elements.

A very practical thing to be included in the motorist's wardrobe is the petticoat of thin kid. It is made of soft, pliable leather, and fits the figure closely. Capes of heavy Scotch goods are greatly in vogue. A popular conception is the long, circular cape, like the picturesque affairs worn by the Italian army officer, modified for feminine usage. Kid waistcoats are long, reaching as low as the knees; they are supplied with large collars and trimmed with buttons. Those of bright cherry red kid are very chic; others are dyed to match with the costume.

Exhibit of E. W. Swanbrough, Hupmobile Agent at Denver Show in Auditorium.

MOUNTAIN SHOW SUCCESSFUL

UNDER the auspices of the Denver Motor Club, the second annual automobile show, held in the Auditorium, has proved to be the most successful exhibition of the kind that has ever been held in Western territory, both from the dealers' point of view as well as an exhibition. The show covered a very large territory, many retail sales were made and proved of great value to the dealers inasmuch as many agencies were located, and the attendance was excellent. There was a total of 63 distinct exhibits, which were as follows:

E. R. Cumbex, Rambler and Mitchell; Overland Auto Company, Apperson, Overland, Baker Electrics, Marion "Flyer" and Winton; Krebbs Covington Auto Company, Haynes, Detroit Electrics, E-M-F and Flanders "20"; Johnston Motor Sales Co., Premier, Fal-Car, Peerless and Everitt; Studebaker Colorado Vehicle Company, Studebaker gasoline and electric and electric trucks; the Sanford Motor Car Company, Croxton-Keeton cars; Mathewson-Marr Aeroplane Company, Mathewson-Marr aeroplanes; Mathewson Auto Company, Thomas "Flyer," Oldsmobile, Reo, Oakland, Columbus and Ohio Electrics, Randolph and Reliance trucks; E. W. Swanbrough, Hupmobile; the Commercial Motor Car Company, Buffalo cars and trucks; Ford Motor Company, Ford cars; Fritchie Auto & Battery Company, Fritchie Electrics; Welch Motor Car Company, Welch cars; A. T. Wilson, KisselKar, Black-Crow and Empire; the Havens Motor Car Company, Frayer-Miller trucks and Dorris cars; Colburn Auto Company, Renault and Colburn cars; Michaels & Middlekauff, Parry cars; F. A. Trinkle, Brush runabouts; John Deere Plow Company, Velie cars; Arapahoe Motor Company, Elmore.

The territory covered by these exhibitors is Colorado, Wyoming, New Mexico, Arizona, Utah, Idaho and Nebraska. There was a total of 53 agencies placed by the exhibitors while the show was in progress. The exhibitors of automobiles secured good prospects for a total of 174 agents throughout the territory.

The Auditorium in which the show was held is the largest building in the West, but it was found necessary to place some of the smaller exhibits in the large corridors on account of lack of space on the main floor. The building was beautifully decorated, the general color scheme being worked out in white and green. While there were a great many cars in proportion to the amount of floor space available still the show did not present a crowded appearance; this was due to the care and judgment which the exhibitors exercised at the request of the club. The aeroplane exhibited by the Mathewson-Marr Aeroplane Company was quite a feature and attracted a large number of people.

NEWS FROM BEYOND THE ATLANTIC

French Show Still in the Air

Paris, Feb. 23—After the bulk of the automobile manufacturers of France have broken away from the Automobile Club of France and joined hands with the aero constructors for the holding of a joint aero and auto show, the national club has voted a resolution in favor of its own automobile show, to be held in the Grand Palais as usual. Thus, if this decision is persisted in, there will be two shows in Paris this year, compared with none in the year 1909. The club's excuse for holding a show after the manufacturers have broken away is that last year it passed a resolution that a show should be held in 1910, and cannot now depart from it.

Although the manufacturers, grouped in the Syndicate of Constructors, are resolved that the show shall be entirely in their own hands, they do not appear to be thoroughly satisfied with the step they have taken in signing an agreement for a joint show with the aero men. This will certainly be better than no show at all, but it is quite possible that the club may give up the idea of holding an exhibition at which exhibitors will be scarce, and that the few manufacturers who still stick to the club may desert that body. This would give the Syndicate of Constructors an opportunity to hold their show without opposition, with the Automobile Club of France as a figurehead, if it so desired, provided, of course, that the aero manufacturers would release them from their contract. But it is not certain that the aero manufacturers will be desirous of dissolving partnership, for, not yet being a very important body, they have everything to gain by combining with a powerful group of automobile manufacturers. The latter are only certain of winning if the club shows fight, in which case they will hold their joint show in the Grand Palais, while the club, having very few firms at the back of it, will either have to organize a tenth-rate exhibition or go out of business entirely.

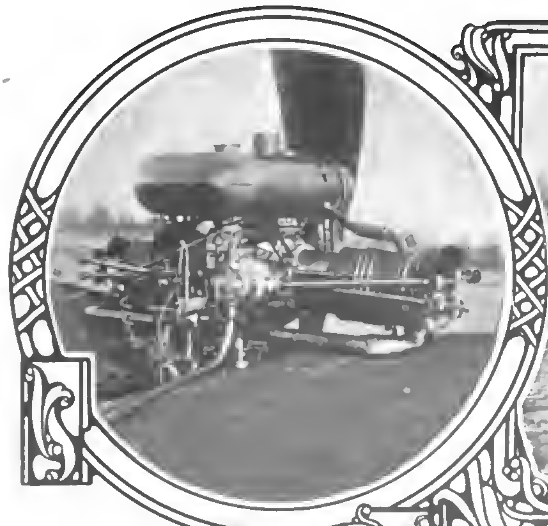
Through its manufacturers' section, the club has already put forth the conditions on which it will be willing to hold a show. Among the changes are uniform stands, with decorations, lighting and all fitting provided by the organizers; no reserved places for the oldest-established or most successful racing firms, and a sharing of the profits among the firms represented on the joint organizing committee. It is on these democratic lines that the manufacturers desire the show to be held, but when this programme was put forth by the manufacturers' section of the club, a contract had already been signed with the aero manufacturers. In addition, the manufacturers would like to see the club in a minority on the joint organizing committee, and the club still has the idea that it ought to occupy the premier position.

An endeavor is being made to arrive at a common understanding, but it is difficult to foresee the result, for, even if the club agrees to a new joint committee, on which the manufacturers will have a majority, it will be necessary to get the consent of the aeronautical manufacturers to a repeal of the present agreement for a combined show before a distinct automobile exhibition can be held. The Syndicate of Constructors, which signed the agreement with the Aero Association for a joint show, is composed of the following firms: Berliet, Léon Bollée, Bozier, Brasier, C. G. V., Chenard & Walcker, Clément-Bayard, Cohendet, Darracq, Delage, Delahaye, Delaunay-Belleville, Lorraine-Diétrich, Doriot-Flandrin-Parant, Grégoire, Harlé, Hotchkiss, Motobloc, Niclausse, Panhard-Levassor, les Fils de Peugeot Frères, Renault Frères, Rochet-Schneider, Rolland-Pilain, Sizaire & Naudin, Turcat-Méry, Vinot & Deguingand, Weyher & Richemond, and Zedel.

Clement Monoplanes Appear

Paris, Feb. 23—Aeroplanes built in series, listed on the catalog and sold complete ready for the air, are now an item of at least one French firm of automobile manufacturers. The Clément-Bayard Company has long been interested in aeronautics, and has contributed towards the experimental construction of airships and aeroplanes, but it was not until the Santos-Dumont type was perfected by the young Brazilian that it decided to catalog a flying machine.

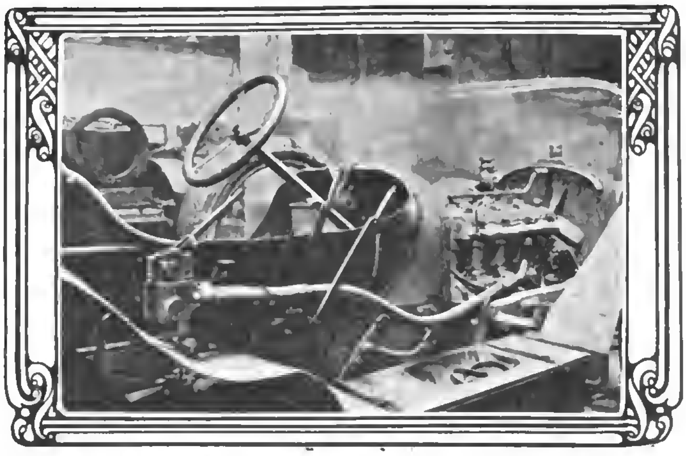
The first series left the works this week, having been constructed entirely in the automobile factory, with the exception of the wing frames. Nothing has been changed on the design, but there are considerable changes in the method of construction, the former bamboo frame having been abandoned in favor



Rear of New Clement-Bayard Motor

Jean Molsant, a Newcomer in Aviation, Uses a Gnome Motor on His Monoplane of a framework constructed entirely of light steel tubing. The only wood used in the aeroplane is found in the wings, which are made in three distinct sections, partly with a view to easy dismounting and storing, and also to allow replacements to be made at a decreased cost.

A special motor has been designed for this popular type of aeroplane. It is a two-cylinder double-opposed model, with steel cylinders of a bore of 5.1 inches, and a stroke of 4.7 inches. The water jacket is of copper, attached. The motor is mounted in the centre and at the forward edge of the wings, where it drives a two-bladed wooden propeller with a diameter of 78 inches. The only really distinguishing feature of the motor is the valve mechanism, inlet and exhaust being side by side in the head and worked off a single cam. Ignition is by high-tension magneto, with both water and oil circulation assured by pump. The radiator, consisting of a series of plain copper tubes, is mounted on the under surface of the wings.



The Jaugey Carbureter Is Placed Alongside the Driver

Gasoline Gauge for Customs

Paris, Feb. 23—A two-fold object has been attained in the new gasoline gauge produced by the French firm of Laforce: the instrument shows at all times the amount of fuel in the tank, and is also a register of every drop of gasoline passed through the filler. Its principle is simple, and it is none the less effective. In the centre of the tank is mounted a copper tube, with a diameter of about four inches and an internal spiral groove. A circular metal float is carried within the tube and is fitted with a couple of ears, so that both on rising and falling it must follow the spiral path of the groove. In addition, there are within the tube two metal rods passing through the float without being attached to it, united at their base by a transverse bar, and at the upper extremities by a circular plate. The float is free to slide up and down the two rods, but as it is secured within the spiral groove of the tube it must at the same time carry the two rods round with it in one direction for a rise and in the opposite direction for a fall of the fuel.

All that is necessary to transform this apparatus into an indicator is to affix a vertical stem on the centre of the upper plate and attach a needle to it, either directly or through gearing. With a gradual dial below, the amount of fuel will be accurately indicated. This is what has been done with the Laforce instrument, the needle being geared down, and the dial placed either horizontally, to lie on the top of the tank, or vertically by the use of bevel gearing. With a sufficient diameter of tube there is no danger of the float wedging in its groove, nor, with a proper construction, of friction between the float and the rods on which it ascends and descends. The fuel, being contained within a tube, is not given to rolling, thus allowing the indicator hands to be very steady. It responds immediately to a sudden change of level, as is shown by filling up the tank as rapidly as possible.

By a very simple arrangement of gearing, it is possible to fit up a totalizing needle, only recording on the rise of the float. Thus, all gasoline poured in it is registered, but on the fall of the float the needle remains stationary, only to operate again when the float rises. With this and a distance recorder, it possible to accurately gauge the mileage per gallon, as well as the total consumption for any given period.

The indicator has been designed to operate with equal accuracy for inclined or flat-bottomed tanks. For the former a false bottom is fitted, and the tube carried down to the lowest level of the tank, to which connection is made in a suitable manner. By this means the first pint of gasoline finds its way to the central tube, raises the float, and is indicated by the dial. Attention has been paid to this feature, with a view to having the instrument officially recognized by the Paris municipality. As all gasoline passing into the city of Paris must pay a duty of about two cents a pint, it is necessary that the amount on board the car should be accurately determined, and that, even when only a few pints are present in the bottom of a sloping tank, they should be registered. The indicator is now undergoing tests which, if satisfactory, will allow the instrumentt to be fitted to automobiles, sealed by the authorities, and its figures accepted by all the employees as the official amount of fuel in the tank. This will avoid the present inevitable disputes between drivers and officers, with the usual unsatisfactory indicators and the still more unsatisfactory measurements with a stick.

EAST IS CLAMORING FOR THE GLIDDEN SUBSTITUTE

WITH the decision to plant the Glidden Tour in Southwestern soil, starting at Cincinnati and traversing a course through a half-dozen States, including Oklahoma, ending at Chicago, comes the conviction that the East will be bared of opportunity, and that the Glidden tryout will be a makers' institution, particularly the makers of relatively low-priced cars, most of whom have their plants in the West.

It has apparently been decided that the opening up of new territory will be for the good of the automobile, and that acquaintance with the roads as they are in the Southwest should be made. It is also likely that an effort such as this will, in some measure, tax the capabilities of the automobiles which will be entered. No matter what the advantages are, or who is so wise as to consider it desirable to abandon over 50 per cent. of the whole population of the United States, the fact remains that unless the wisdom thus displayed includes some sort of a run in that part of the United States which is inhabited before the end of the year the makers of the more pretentious types of automobiles will have no opportunity to display the qualities of their wares to their prospective customers, and will have to depend upon publicity reports as they will emanate from the "wisdom makers" who will accompany the Gliddenites on the Southwest venture.

The purchasing public is scarcely likely to be much interested in the character of newspaper reports which come under the conditions of a Glidden Tour in a remote section of the country, and it must be that the sole purpose of projecting a run of this character as to enable the makers of the cars which will be entered to obtain experience under conditions which will afford to them the advantage of comparison. Let it be taken for granted that the makers who will support the Glidden Tour this year will find it sufficiently edifying to satisfy their needs, but the fact remains that the East, or the centers of population in the Middle West, are left out in the cold, as the situation shows on the surface.

Last year the Munsey Run offered a slight opportunity to the Eastern patrons of the automobile industry, but it was not, according to some, an ambitious effort, and as for the remaining "pink tea" efforts, they do not count. The Munsey Run idea will scarcely suffice for the future, and the plant here is that there is apparently nothing scheduled for the coming season ,which is worthy of the high estate of the automobile, and the expectations of the Eastern makers and the citizens who support them.

If the wise ones have something up their "leg of mutton sleeves" which will satisfy the situation, the restiveness of the many who fail to fully appreciate the provision made for them will be subdued. It does not look, however, as if they are to be favored by the intelligence which would sound as music to their ears, and they are strong in the fear that there will be no endurance contest worthy of the name, which will permit an Eastern maker to participate in, unless he ships his automobile by rail a distance of a thousand miles, and enters it in a run over roads which are not yet made, with bats for spectators for the most part.

If a run were to be inaugurated it might have for its itinerary any one of a dozen routes which would sum up to the total required distance and prove to be sufficiently strenuous to tax the capabilities of automobiles, prove the harmonious relations which are supposed to reside in them or develop the weak points. As an illustration of a run of this character the following might be considered:

Starting from New York, through New Jersey, Pennsylvania, Ohio, Indiana, Michigan, perhaps across lower Canada, New York State (via Niagara Falls), Massachusetts, and ending at Boston. This is a mere suggestion of a run which would be interesting to the participants, tax the qualities of the cars, and permit the greatest possible number of citizens to note the results. Publicity would be of a more substantial character and it would be maximum in scope, because the tour would pass the door of more newspapers in a single day than the Glidden Tour will cast a shadow upon from the time it leaves Cincinnati until it angles into Chicago.

Heretofore, and especially last year, the rules which governed the Glidden Tour were far from satisfactory to many of the contestants, and discredit was cast upon the situation as a result. If the public is to be interested in contesting machines, there must be no question as to the fairness of the rules, or the manner in which they are observed. If interest could be aroused and agitation should result in some effort to bring about an endurance contest for the East, this question of the rules would become a serious matter and should receive concurrent discussion. Unless the run can be brought about, however, the question of fair and comprehensive rules to govern the same should scarcely have to be wrestled with. There is no time like the present for the discussion of this matter, and the aim here is to bring the glaring deficiency to public notice with the expectation, perhaps, that others will participate and that something may come of it.

(Signed) R. G. KELSEY.

RECEPTION AT THE WHITE FACTORY

CLEVELAND, Feb. 28—A novel event in the annals of motor car manufacturing was the reception held last Saturday at the White Company's factory, St. Clair avenue and Seventy-ninth street.

Although the greater part of the factory was completed and occupied three years ago, it was only last August that the new six-story administration building was completed and the wholesale offices moved from their former location in a downtown office building. Last Saturday's event, therefore, took on the aspect of a house-warming of the visitors to make a thorough inspection of the factory.

The arrangements made for the reception were not unlike those usually made for a reception in a great private house. A canopy was stretched from the driveway to the entrance of the factory and there was a retinue of door tenders, ladies' maids, etc., to look after the comfort of the visitors. The leading caterer of the city was on hand with a half hundred of his assistants and all the florists in town were called upon to furnish the decorations. The hours announced for the reception were from 1 to 5 o'clock, and during that period more than 1,500 of the socially elect of Cleveland attended.

The guests were received by the directors of the company and their wives, as follows: Mr. and Mrs. Thos. H. White, Mr. and Mrs. Windsor T. White, Mr. and Mrs. Rollin H. White, Walter C. White, Mr. and Mrs. Henry W. White, Mr. and Mrs. Ernest W. Hulet, Mr. and Mrs. M. B. Johnson, Mr. and Mrs. Frederic S. Porter and Mr. and Mrs. Albert R. Warner. Then the guests, in parties of a dozen or more, were conducted throughout the factory. After the guests had been conducted through the factory they were conducted to the "banquet hall," a large room which, in normal times, is used as a receiving room for raw material.

In connection with the reception, a little souvenir bulletin was distributed, giving some interesting statistics of the factory as follows: There are 1,500 employees and cars are now being built at the rate of 14 per day, or 84 per week. The weekly production is divided as follows: Forty steam cars, 40 gasoline cars and 4 trucks. Three months are required to build a White automobile.

MORE AND BETTER TRACK AND ROAD RACING RULES

RACING is apparently going to be more widely distributed and more generally interesting this year than ever, despite all predictions to the contrary. At least, that is what the committee in charge seems to think, and with that idea in view, the rules have been formulated so as to cover all possible cases. An additional list of rules is here presented, the first part having been given space in THE AUTOMOBILE for March 3.

Safeguarding Public and Contestants—A promoter must also furnish evidence satisfactory to the Contest Board that he has taken every possible precaution to safeguard the general public and the contestants, including the proper preparation of the roadway, and especially for the prevention of dust, the policing of the course, closing of highways and erecting fences where eeded, and shall file with the Contest Board the original or a certified copy of any and all contracts and agreements made or entered into by him for the accomplishment of such safeguards.

Repairs and Adjustments—All mechanical repairs and adjustments must be made exclusively by the crew of a car.

Repair Pits and Attendants—There shall be located at the start and finish line one repair pit for each car started, not less than 15 feet long and 8 feet wide. Each contestant shall be entitled to have three attendants, two of whom shall be permitted to make replacement of gasoline, oil and water and replacement or replenishment of tires, or crank the motor, when a contestant's car is at a standstill at its pit, but said attendants shall in no case make any mechanical repairs or adjustments to the car or assist in any manner in such repairs and adjustments.

Spare parts, tools, etc., may be laid on the shelf or ledge in front of the pit, and pit attendants, while in the pit, but not otherwise, may band same to the driver or mechanic.

A violation of this rule shall disqualify the car.

Fraud—Any attempt at fraud in the evasion of the definition of stock car and stock chassis and status of the car, on the part of an entrant, shall disqualify the car, the driver and the entrant.

In addition to the foregoing, there is provided a complete set of rules for the running of a road race, including weighing in and weighing out requirements; signal code for contestants; International road symbols for marking the course; road regulations; special duties of officials, etc.

SPECIAL RULES FOR TRACK RACES

Tracks are divided into three classes, viz.:

One-half mile, 1 mile, 2 miles or over, specially constructed speedways.

Tracks Must Be Licensed—Tracks will be inspected by a representative of the Contest Board and if arrangement of fences, buildings, ditches, provisions for laying the dust and other safeguards meet the requirements of the Contest Board, they will be licensed, such licenses expiring on December 31 of each year.

Licenses will not be issued to tracks which from the nature of their surfaces or turns, whether on account of dust, roughness, fencing or otherwise, may be considered dangerous.

Track Meeting Limited to Three Days—No sanction will be granted for a track contest of more than three days' duration.

One-Half Mile Track—No record will be allowed which is made on a track less than 1 mile in length.

Driving Reverse Way of Track—Any contestant who drives the reverse way of a track shall be immediately disqualified, suspended and reported to the Contest Board. The referee has no alternative in this regard.

LONG-DISTANCE RACE RULES

Change of Drivers—No driver shall be permitted to drive or have charge of a car for more than 3 consecutive hours. After the expiration of such 3-hour period he shall not be again permitted to drive until he has taken at least 1 hour's rest.

No 24-hour race shall be permitted on a ½-mile track.

Repairs and Replacements—Repairs and replacements are restricted to the part or parts actually damaged. No completely assembled unit, such as rear construction, transmission gear case, motor, clutch, etc., can be totally replaced unless damaged in all of its parts. When one or more parts of an assembled unit are damaged, such damaged parts only may be replaced.

Other rules added are:

Adequate code of signals to contestants.

Restriction of repairs and adjustments to a car on the track to those which can be made by the driver and mechanic and only such as will enable the car to run to the pit or paddock.

In case of total disability on the track, a car may be towed to the pit or paddock by a car approved by the referee.

Technical inspection during a race of any car which may be considered unsafe.

Stopping and restarting of race not to be announced in advance.

No work to be allowed on a car during any intermission.

SPECIAL RULES FOR HILL-CLIMBS

Provisions previously cited relative to permits to use the public roads and evidence of safeguarding public and contestants must be complied with before sanction will be issued.

Length and Grade—The promoter must file with the Contest Board 10 days before the running of any hill climbing contest a surveyor's certificate of the length of the hill to be climbed and a profile showing the greatest percentage of grade at any point and the average grade for the total distance. These figures must also be stated in the entry blank.

Except for the above, with a few minor amendments, the hill-climb rules for 1909 are unchanged.

RELIABILITY CONTESTS AND TOURS

A summary of these rules for 1910 will be issued shortly.

The complete contest rules for 1910 are now being printed and will be issued as soon as completed.

MILESTONES FOR THE AUTOMOBILIST

Mar. 5-12.........**Boston, Mechanics' Building, Eighth Annual Automobile Show, Boston Automobile Dealers' Association. Chester I. Campbell, General Manager, 5 Park Square.**

Mar. 5-12.........Cleveland, Central Armory, Cleveland Automobile Club, Eighth Annual Show.

Mar. 5-12.........Des Moines, Ia., Coliseum, First Annual Automobile Show, Des Moines Automobile Dealers' Ass'n.

Mar. 7-12.........Albany, N. Y., Armory, Automobile Show.

Mar. 15-19.........Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

Mar. 15-19.........Bridgeport, Conn. Automobile and Aeronautic Show, Bridgeport Automobile Dealers' Assn.

Mar. 17-19.........Louisville, Ky., Automobile Show, Louisville Automobile Dealers' Association, in the Louisville Armory. Hubert Levy, Secretary.

Mar. 21-30.........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo, Launch Club. D. H. Lewis, Mgr., 760 Main St.

Mar. 21-28.........Denver, Col., Convention Hall, Denver Motor Club's Annual Automobile Show.

Mar. 26-Apr. 2...Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

Mar. 26-Apr. 2...Montreal Automobile and Motor Boat Show, Official Motor and Sportsmen's Show Committee of the Automobile and Aero Club of Canada, in the Coliseum. E. M. Wilcox, Manager, 123 Bay St., Toronto.

Apr. 22-29.........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

Jan. 7-14, 1911...**New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.**

Jan. 17-24, 1911.New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.

Feb. 13-25, 1911...Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

RACES, HILL-CLIMBS, ETC.

Mar. 19..........Altadena, Cal., Hill Climb, Licensed Motor Car Dealers' Association, Los Angeles, Cal.

Mar. 20..........Hill Climb, San Francisco Motor Club, San Francisco, Cal.

Mar. 28-29........Savannah, Ga., Endurance Run to Jacksonville, Fla., Savannah Automobile Club.

Apr. 8-10 & 13-17.Los Angeles, Cal., Inaugural Meet, Motordrome.

Apr. 30-May 2...Philadelphia, Roadability Run to Atlantic City, Quaker City Motor Club.

May 2............Flag to Flag Endurance Contest, Denver, Col., to City of Mexico.

June 11..........Wilkesbarre, Pa., Annual Hill Climb Up Giants' Despair, Wilkesbarre Automobile Club.

FOREIGN SHOWS AND RACES

Mar. 19-Apr. 3...Berlin Automobile Show.

Mar. 22..........Elegance Competition at Monte Carlo.

Mar. 27-Apr. 4...Prague, Austria-Hungary, Automobile Show.

Mar. 28..........Brooklands, England, Easter Meeting.

Mar. 31-Apr. 8...French Spring Wheel Competition.

Apr. 2-24.........Turin, Italy, Automobile Show.

Apr. 27-28........Brooklands, England, Two-Day Meeting.

May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.

May 28-June 9...St. Petersburg, Russia, Automobile Exhibition.

June 2-8.........Prince Henry (German) Touring Competition.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

Boston is taking advantage of the presence of the last big show of the year, and the attendance is of a character which seems to indicate that the autoing public will be sorry when it is over. Keen observers have failed to discover a wane of the interest, and it looks as if automobile shows, and the interest which is being taken in the cars themselves, will ultimately end in every man being his own mechanic. For a real study in contrast, there is nothing which will compare with the difference between the first audience which favored an automobile show by its presence, and the critical visitors who now linger over and admire the mechanical masterpieces which make up, for the most part, the automobiles of the year.

In the earlier shows, lack of knowledge of the mechanisms was not limited to the patrons who stood around and wondered why. Demonstrators frequently talked without really saying anything, and, fortunately for them, the audience was indifferent to the discrepancies. As it stands to-day, it would be a most unwise move, were an exhibitor to attempt to explain the reasons why, using an ignorant demonstrator as a mouthpiece. The autoing public is too thoroughly alive to the situation to permit anything of the sort.

In former years selling points were taken advantage of, and in more than one instance enlarged upon, but the mechanical education which is being acquired by autoists in general gives to them a wider view, and they are disinclined to regard a selling point, even though it may be a good one, as representing anything but one of many links in the chain. A real automobile has upwards of 900 different kinds of pieces in its makeup, and a selling point, if it is rested upon 900 different kinds of inharmonious relations, is scarcely to be looked upon as satisfactory.

In the long run selling points will disappear, because, when properly viewed, they represent conspicuous components in the makeup of the machines as a whole. In a sense, considering this fact, they portray a certain lack of harmony, and it is scarcely to be supposed that selling points will be readily picked out of a distinctly harmonious mechanical masterpiece. As an indication of the growing confidence of autoists in the products which are being exhibited, is the almost entire lack of demand for what has heretofore been termed "ideal" constructions. The average buyer, at the present time, is more inclined to look for clearance of the adjacent parts, absence of ill-shaped members of the mechanism, good oiling facilities, proper brakes, and the earmarks of the designer who indicates by his work that an automobile is a kinetic machine, rather than a contrivance to be drawn.

Night riding is scarcely to be enjoyed by prudent autoists unless they are assured that the steering gear is capable, the brakes effective, and the lighting is eminently satisfactory for the purpose. There are very few, if any, automobiles which are so poorly provided with mechanical contrivances as the steering gear and braking system, that it would be unsafe to go about at night, but the lighting question has always seemed to be in need of just a little more attention. Many autoists, especially those who own electric vehicles, have expressed the hope that electric lighting will ultimately become available for this use, and at the shows this year, the many evidences of refinement of this character of equipment would apparently indicate that the autoist who prefers electric lights has merely to engage them.

The improvements wrought have been all along the line. The batteries for this work are much more substantial. The lamps, they being of the tungsten type, are of an extremely high watt efficiency, hence the energy dissipation is reduced to a point so low that the battery lighting systems are quite satisfactory. For those who desire to tour, hence run the chances of frequently being far away from a charging source, the battery may be supported by a charging dynamo, and it is in this particular direction that the greatest amount of improvement is to be noted. The dynamos are now so installed that they will operate at a constant speed when driven by a variable speed engine with simple and strong mechanism.

Nitrogen, which is an inert gas, and almost devoid of refrigerating properties, is now being used instead of gasoline for fuel in automobile motors, to a limited extent, abroad. Energy is transplanted into the nitrogen after it is separated out, by the process of compression, it being the practice to hold the nitrogen in a tank under a pressure of 200 atmospheres (substantially 3,000 pounds per square inch). Improvements in the process of abstracting nitrogen are at the bottom of this new situation, and accounts have it that the performance of the nitrogen motor is extremely good. The gas works expansively, and a well designed steam engine is representative of the principles involved in the motor construction.

INDEPENDENTS ORGANIZING FOR MUTUAL PROTECTION

TAKE IMPORTANT ACTION AS PREVIOUSLY ANNOUNCED IN "THE AUTOMOBILE"--NEW IDEA TO BE SUBSTANTIAL SUCCESSOR TO AMERICAN MOTOR CAR MANUFACTURERS' ASSOCIATION, BUT MORE AGGRESSIVE IN CHARACTER

CHICAGO, Mar. 7—As pointed out in THE AUTOMOBILE in the issue of February 24, various of the independent makers were seriously considering forming a new association for the protection and good of the makers who are not members of the A. L. A. M. At that time the under current of events was very carefully concealed, and THE AUTOMOBILE was not in a position to release details. History is being manufactured at a high rate of speed these days, and the public, especially the portion which takes an interest in affairs automobile, lives in anticipation of a campaign which will counteract the aggressive publicity of the A. L. A. M.

Some of the details of the proposed new organization are now to be had, although speculation must still occupy a niche in the proceeding. There was a meeting of mysterious interests which was held in Chicago last Sunday night with the idea of promoting an association which will be "an organization for mutual protection against the Association of Licensed Automobile Manufacturers." This association may not be built exactly according to the old A. M. C. M. A. lines, however, but it is said that a serious attempt is being made by unlicensed interests to bring together those manufacturers outside of the Selden bulwarks, and whose most powerful weapon will be a patent which is said to have to do with bevel gear drive as utilized by most makers.

It was not until Saturday morning that the secret leaked out. Then it was whispered around that there was to be a meeting held that day at the La Salle hotel, but no one seemed to know who was to be present or who had called it. A quiet investigation, however, developed that the movement was by no means a new one, it being stated by several, who evidently were on the inside to a certain extent, that during the last Chicago show they had been approached by one E. R. Russell, who claimed to be an engineer and who said he was interested in a tire and axle concern located at Connersville, Ind., and also in an electrical construction company in Cleveland. This Mr. Russell told several of the unlicensed makers that he and his associates had secured control of a valuable patent and that he hoped to bring about an organization of unlicensed makers which could use the patent which he controls as a weapon against the A. L. A. M. He told the makers at the show that he intended holding a meeting later on, at which his association would be formed.

This meeting was held Saturday at the La Salle hotel but as to its results no one outside of those in Mr. Russell's confidence knows and Mr. Russell himself will not talk for publication, he having informed the newspaper men that it would be another week or ten days before he would be in a position to say anything. Despite Mr. Russell's secrecy, however, it has been learned that he has made some progress. All those whom he invited to attend Saturday did not go, although several representatives of unlicensed cars paid him a visit, more with the idea of learning of what he had to offer than to join, it is said.

One of those who paid a visit to Mr. Russell Saturday tells of star chamber proceedings. He found Mr. Russell and a Mr. Moore, a Chicago attorney, located in a suite of rooms on the eleventh floor of the La Salle hotel, and only one applicant was admitted at a time, coming in one door and exiting from another so that in this manner the proceedings were shrouded with great mystery. When the applicant reached Mr. Russell and his lawyer, he was told that the association already had been formed but that it was desirous to secure several more manufacturers before announcing the general plans of the association. Mr. Russell would not tell the applicants what concerns were affiliated with him nor would he go into details as to his patent holdings.

"You put in your application, pay us $1,000, and we will consider you as a candidate," he is said to have told one of the manufacturers' representative who called upon him; "When you are admitted you will be told everything."

"But who will pass upon our application?" asked this manufacturers' representative?

"We have a committee composed of one representative from seven manufacturing concerns which pass upon applications," Mr. Russell is said to have replied, but he would not divulge the names of any of them nor could the prospective member gain any further information unless he would put up the $1,000 asked.

From all it can be learned at the present time, the association is as yet in embryo. It is said that Indiana is the fountain-head of the affair and that several Hoosier manufacturers have been instrumental in starting Mr. Russell along these lines. As to the identity of the Indianian it is hard to conjecture, because most of the prominent Hoosier concerns already are members of the A. L. A. M. Also it is declared that neither Henry Ford nor Thomas B. Jeffrey are interested in the movement.

Following the meeting at the La Salle Saturday, Mr. Russell left Chicago yesterday morning, telling those interested, that he could be reached by mail at the Claypool hotel in Indianapolis.

LARGEST MERGERS MAY BE MERGED, IF THE STORY HOLDS

PERSISTENT rumors, supposedly having their origin in New York, have been floating about Detroit to the effect that an amalgamation is shortly to be effected between the General Motors Company and the recently organized United States Motor Company. It is an open secret that the advent of the United States Motor Company was not welcomed with any great outburst of joy by the combination in which W. C. Durant is the moving spirit. It is even recalled that in its earlier days General Motors made overtures looking toward taking over the Maxwell-Briscoe Company, strongest link in the new chain, although nothing came of the attempt. Since that time there have been various reports spread broadcast only to be denied in toto. The most recent gossip is to the effect that a giant merger is being discussed which would include a majority of the big factories throughout the country and make either one of the present corporations appear insignificant by comparison. Color was lent this rumor by the presence here for several days of Benjamin Briscoe, prominent figure in the United States Company. However, Mr. Briscoe denies that his visit possessed any special significance.

"There is nothing to the story of an amalgamation so far as we are concerned," said he. "No overtures have been made, no negotiations undertaken, in fact, nothing of that nature has been done. The United States Motor Company is thriving, and there may be further developments in that direction in the near future. But the rumored amalgamation is without foundation so far as I know."

Nevertheless, the story declines to down, and the presence in New York this week of several local manufacturers give added weight to the belief that something is about to happen.

HENRY FORD COMMENTS ON THE SELDEN SITUATION

I HAVE noticed in the press throughout the country that the A. L. A. M. are to wage war against what they see fit to designate as "unrecognized" automobiles to educate the public against buying them, and the stockholders of unlicensed companies against making them. At least this is what they would like the public to believe is their true motive, and it would be a most philanthropic undertaking, the like of which is rarely seen in commercal life. But they do the public a gross injustice to assume that it is so unintelligent as not to be able to see through the scheme. It should be, and no doubt is, so evident to the public that the real motive of this war of the A. L. A. M. against "unrecognized" automobiles is a selfish one, and is neither to protect innocent investors from putting their money into new enterprises nor to protect buyers from buying cars for which they will not be able to secure parts, but is for the purpose of maintaining their present extravagant prices.

Of course, I can appreciate why President Clifton and his associates want to maintain the present high prices of their cars. If they can continue to reap large profits on their product, they will do so even though it means stifling competition.

That is the easiest way to maintain profit—much easier in fact, than devising ways and means of reducing the costs.

I do not understand all the motives of this Licensed Association in its campaign of educating the public to the point where it will recognize the advantages alleged by the association to accrue from purchasing its product, but it occurs to me that a much shorter way would be to go to the courts and have the unlicensed manufacturers enjoined from producing cars. That would beat trying to educate the public to refrain from buying these tabooed cars.

Mr. Clifton is entirely correct in saying that many promoters are pointing to the profits made by a few of the old time manufacturers, thereby encouraging the formation of new companies and inducing innocent people to place their money in these said new companies on the alluring representation of profits made by the old companies. He is equally correct when he says there are a lot of these companies doomed to failure, but there are, too, a lot of the 72 varieties doomed to failure. In fact, in looking over the list of the 72 varieties, I think I can safely predict that there will be more failures among those makers during the next five years than there will be among the so-called unrecognized automobile manufacturers.

The Licensed Association does not grant to buyers of licensed cars any protection that is not granted to buyers of Ford cars. Time will prove whether or not the protection this association affords even nearly equals the protection a Ford buyer has. In spite of this intimidation campaign, no Ford buyer need fear an infringement suit. The Ford Motor Company will furnish a national surety bond indemnifying Ford buyers against suit. As the assets of the National Surety Company, of New York, combined with the assets of the Ford Motor Company, total approximately $12,000,000, it is evident that Ford buyers and present owners have every assurance of ample protection.

It should be evident to the members of the A. L. A. M. that the automobile industry must take its course with other industries, must allow the weeding out of the unfit, and must permit of the continuance of the industry by those who are left with the "Survival of the Fittest." This is exactly as in all other lines of trade. If the manufacturers of these 72 varieties were willing to work along those lines, they would be spending their money, time and effort in educating the public, and they would be devising ways and means to be among the surviving. Instead they are trying to build up a monopoly by means of this so-called Selden patent, a monopoly which will eliminate their having to compete for a position.

I am going to continue our fight along the same honest lines as always, and to trust to our courts, in which I have the greatest confidence, to see that justice is done. Between courts it is not unusual to have a difference of opinion. The expectation of such a difference is evident in Judge Hough's opinion. He predicts that the matter will be taken to the court of appeals, to which court we will surely take it, and here is something more to consider. We expect, later, to tell the public something else of interest.

(Signed) HENRY FORD.

GLIDDEN WILL START FROM INDIANAPOLIS

At a meeting of the administrative officials of the A. A. A., which is now going on at Boston, it is understood that the question of the starting of the Glidden Tour and the laying out of the tentative route will be disposed of in favor of Indianapolis as the starting point. After the original announcement of the proposed route, which was to start at Cincinnati, the Mitchell Ranger was started out and was given official recognition by the press generally, and Chairman Butler of the A. A. A. Contest Board announced in THE AUTOMOBILE that the official pathfinder had not been selected up to that time, and that the selection was finally made in favor of a Chalmers car. It transpired simultaneously, that makers of automobiles in and around Indianapolis, petitioned the A. A. A., and offered as an argument for the starting of the tour from Indianapolis instead of Cincinnati, the well known fact that Indianapolis is an automobile center of substantially the first magnitude.

Until the administrators of the A. A. A. reached a final conclusion at the meeting which is now being held at Boston, it will not be possible to procure a confirmation of the change as here referred to, but a canvass of the situation, in so far as it is possible under the circumstances, rather goes to show that Indianapolis is likely to be honored. The change will be made on the ground that there are many automobile makers centered around Indianapolis and their wishes carry weight, whereas Cincinnati ranks relatively low as a manufacturing city with automobile making as a factor.

UNITED STATES MOTOR CO. COMPLETE

That the United States Motor Company, the recently organized $16,000,000 corporation, which has so far absorbed the four plants of the Maxwell-Briscoe Motor Company, of Tarrytown, N. Y.; New Castle, Ind., and Auburn, R. I., and the mammoth plant of the Columbia Motor Car Company, of Hartford, Conn., is destined to stand in the front ranks of the industry is amply demonstrated by the personnel of officers elected recently at the first annual meeting of the corporation.

Mr. Briscoe, besides being at the helm of the Maxwell-Briscoe Motor Company, is interested in many concerns connected with the industry. Among the many positions which he holds is the presidency of the Manufacturers' Contest Association, having recently been elected for the second time, and is a director of the American Automobile Association, both positions being of a complimentary nature in honor of his high standing in the industry.

Associated with Mr. Briscoe in the new enterprise is J. D. Maxwell, first vice-president; H. W. Nuckels, vice-president; Carl Tucker, treasurer; J. W. Wellington, assistant treasurer; F. D. Dorman, secretary, and W. F. Crosby, assistant secretary.

Announcement was made last night at the Boston Show that Horace De Lisser, the well-known president and general manager of the Ajax-Grieb Rubber Company, has been elected to the vice-presidency with entire charge over the sales, of the new United States Motor Company, in which the Maxwell-Briscoe Motor Co. and the Columbia Motor Car Co. are already known as members.

LARGE CASH PRIZES AT LOS ANGELES MOTORDROME

At the inaugural seven-day meet of the new Los Angeles motordrome, April 8-10 and 13-17, 37 events will take place. Races of all sorts will give every form of car, either specially built or stock, an opportunity to do its best without having to face odds of being outclassed. In addition to this it is said that the management will hold a twenty-four-hour race and the American Automobile Association has been asked to set aside April 30 and May 1 for this contest.

For the inaugural meet large cash prizes are offered for professional events and handsome trophies for amateur races, and the fields in each class are expected to be larger than usual. The handicapping will be in charge of A. L. McMurtry. The complete program for the ten days' sport follows:

Event 1—One-mile time trials, free for all. First prize, cup; second prize, cup.

Event 2—Ten mile, stock chassis, 161 to 230 cubic inches. First prize, cup; second prize, cup.

Event 3—Ten miles, stock chassis, 451 to 600 cubic inches. First prize, cup; second prize, cup.

Event 4—Twenty miles, free-for-all handicap. First prize, $100; second prize, $50; third prize, $25.

Event 5—One hundred miles, stock chassis, 301 to 450 cubic inches. First prize, trophy and $300 in gold; second prize, $150 in gold; third prize, $100 in gold.

Event 6—Five miles, stock chassis, 231 to 300 cubic inches. First prize, $50; second prize, $25.

Event 7—Five miles, free-for-all. First prize, $100; second prize, $50.

Event 8—Twenty miles, stock chassis, free-for-all; open only to amateur drivers. First prize, trophy.

Event 9—Ten-mile chassis, 231 to 300 cubic inches. First prize, cup; second prize, cup.

Event 10—Fifteen-mile, free-for-all handicap. First prize, $150; second prize, $50.

Event 11—Ten-mile, stock chassis, 451 to 600 cubic inches. First prize, $75; second prize, $25.

Event 12—One hundred-mile, stock chassis, 161 to 230 inches. First prize, $250 in gold; second prize, $100 in gold; third prize, $50 in gold.

Event 13—Ten mile free for all. First prize, $100; second prize, $50.

Event 14—Twenty-five-mile, stock chassis, 301 to 450 cubic inches. First prize, $100; second prize, $50.

Event 15—Ten mile, free-for-all handicap. First prize, $100; second prize, $50.

Event 16—Ten-mile, stock chassis, 600 cubic inches or under. First prize, $100; second prize, $50.

Event 17—Ten-mile, free-for-all, open to amateur drivers only. First prize, cup; second prize, cup.

Event 18—Five miles, stock chassis, 161 to 230 cubic inches. First prize, cup; second prize, cup.

Event 19—One hundred miles, stock chassis, 231 to 300 cubic inches. First prize, $250 in gold; second prize, $100 in gold; third prize, $50 in gold.

Event 20—Ten miles, handicap, open only to amateur drivers. First prize, cup; second prize, cup.

Event 21—Twenty miles, stock chassis, 161 to 230 cubic inches. First prize, $100; second prize, $50.

Event 22—Ten miles, stock chassis, 451 to 600 cubic inches. First prize, cup; second prize, cup.

Event 23—Five miles, chassis, 231 to 300 cubic inches. First prize, $100; second prize, $50.

Event 24—Twenty-five miles, stock chassis, 301 to 450 cubic inches. First prize, cup; second prize, cup.

Event 25—Fifty miles, free-for-all. First prize, $250; second prize, $100; third prize, $50.

Event 26—Ten miles, stock chassis, 161 to 230 cubic inches. First prize, cup; second prize, cup.

Event 27—Ten miles, stock chassis, free-for-all, open to amateur drivers only, for California championship. First prize, cup; second prize, cup.

Event 28—Fifteen miles, stock chassis, 231 to 300 cubic inches. First prize, cup; second prize, cup.

Event 29—Ten miles, stock chassis, 301 to 450 cubic inches. First prize, $100; second prize, $50.

Event 30—Five miles, free-for-all handicap. First prize, $100; second prize, $50.

Event 31—One hundred miles, stock chassis, 451 to 600 cubic inches. First prize, trophy and $1,000 in gold; second prize, $500 in gold; third prize, $300 in gold; fourth prize, $200 in gold.

Event 32—Ten miles, free-for-all, best two out of three heats. First prize, $200; second prize, $100.

Event 33—Two-hour race for stock chassis over 600 cubic inches. First prize, $250; second prize, $100; third prize, $50; fourth prize, $25.

Event 34—Five miles, stock chassis, 301 to 450 cubic inches. First prize, $75; second prize, $25.

Event 35—Ten miles, free for all. First prize, $100; second prize, $50.

Event 36—Twenty-five miles, free-for-all, open only to amateur drivers. First prize, cup; second prize, cup.

Event 37—Ten-mile handicap for cars under 450 cubic inches. First prize, cup; second prize, cup.

TROPHY FOR FREE-FOR-ALL

The Speed Carnival of the Florida East Coast Automobile Association, which will be held March 22 to 25 on the famous Daytona Beach, will introduce the initial race for an entirely new prize, which is known as the W. B. Five Thousand Dollar Trophy, and which must be won twice in succession before becoming the property of the winner. This trophy is offered for the 300-mile free-for-all race, as this contest offers the widest field of entries and the most sportsmanlike competition. This splendid product of the jewelers' art is made of solid silver and stands nearly 5 feet in height and in form is a pure Greek urn surmounted by the figure of Victory holding a laurel wreath. The base is ornamented with winged wheels and bears in relief a racing car at full speed. This beautiful and valuable prize is presented by the W. B. Corset Company, of New York.

Trophy for Florida Spsed Carnival

ANOTHER TRACK IN SIGHT

Negotiations are being made by a company of New York capitalists for the purchase of the northern end of Monmouth Park, near Eatontown, known as the new part. This section contains 390 acres and has a splendid mile and three-quarter track. If the deal goes through many thousands of dollars will be spent by the capitalists to make this the finest automobile race track in the country.

FRISCO CLIMB SUCCESSFUL

San Francisco, Mar. 7—In the first hill climb of the season held here recently, by the Automobile Trades Association, of Alameda County, a wet track prevented fast time, but otherwise, the event was a great success. The contest was held on the Oakland avenue grade in Oakland, across the bay, the length of the grade being 6/10 of a mile. The greatest honors went to the Buick and Corbin cars. Frank Murray, driving a Buick, took three first places, and in the 40 roadster made the fastest time. The Corbin took its class event and in the free-for-all equaled the best time of the day as made by a Buick. The summaries:

Car	Driver	Time
RUNABOUTS, $1,000 AND UNDER		
Hudson	C. Allen	1:06
RUNABOUTS, $1,501-$2,000		
Buick 40	F. Murray	:52⅕
Auburn	F. Hurst	1:18⅘
RUNABOUTS, $2,001-$3,000		
Chalmers 40	J. Bemb	:58⅗
TOURING CARS, $1,500 AND UNDER.		
Buick 30	F. Murray	1:00
Paterson 30	L. L. Gummow	1:15
TOURING CARS, $1,501-$2,000.		
Buick 40	F. Murray	1:04
Elmore	P. F. Gillette	1:37
TOURING CARS, $2,001-$3,000		
Corbin	A. Loughead	1:06⅕
FREE-FOR-ALL		
Corbin	A. Loughead	:52⅕
Buick 40	F. Murray	:56
Maxwell	C. King	:57⅗
Chalmers 40	J. Bemb	1:03
Gillette Pup	P. F. Gillette	1:06

AMONG THE GARAGES

One of the new Parry cars, standing in front of the immense factory at Indianapolis, Ind. This is the car which exemplifies the "Parry Idea"

Wilkesbarre, Pa., automobilists have received the announcement of the opening of Lee's garage, at 182 North Pennsylvania avenue. The garage covers four city lots, with a depth of 112 feet. It sets back 40 feet from the sidewalk, leaving a large yard paved with cement. The building has at present a storage capacity of 35 cars, and is so planned that the second story, when added, will accommodate 90. Arrangements have been made so that this enlargement can be made during the present season without vacating the building.

Commodore C. Stanley Grove has purchased the States garage, Atlantic City, N. J., on Atlantic avenue between States and Delaware avenues. This is the newest and handsomest in the city, having been opened only last July. During that time its builder, G. T. Lippincott, made it also one of the most popular. It is a two-story fire-proof building on the Roebling system, 72 feet front and 100 feet deep. The new owner will continue the same liberal policy.

The new plant of the Regal Motor Company, near Walkerville, Mich., is rapidly nearing completion, and will be finished within two weeks. An order for mechanical equipment has already been placed.

The new plant of the Fiat Automobile Company in Poughkeepsie, N. Y., is practically completed, and the machinery is now being installed.

Brief Personal Mention

C. J. Holdrege, formerly sales manager of the Stromberg Motor Devices Company, of Chicago, has transferred his flag to the Ideal Electric Company, of Chicago, with which concern he will occupy the same position. The Ideal Electric Company is making rapid advances in the electric vehicle field, and the new sales manager is busy making suitable arrangements to dispose of a large and important product.

J. B. Sperry, until recently connected with the Motor Car Company of Washington, D. C., has joined the selling force of the E. R. Thomas Motor Branch Company in Boston. Mr. Sperry has had several years' experience in the automobile business, the greater part of which was handling Thomas cars in western territory.

C. S. Henshaw, manager of the E. R. Thomas Motor Branch Company, of Boston, Mass., has secured the services of A. D. Frost as assistant manager. Mr. Frost was formerly connected with the Thomas Flyer agency in New York, and later was sales manager for the Herreshoff Motor Company, of Detroit.

R. T. Mitchell, well known to the Cleveland automobile trade, has joined the sales force of the Babcock Electric Garage & Sales Company, of Cleveland, and in the future will have charge of the sales of the Babcock for the State of Ohio.

C. R. Mertens, who severed his connection with the Columbia Motor Car Company some time ago to enter the service of the Whitlock Coil Pipe Company, has again returned to the Columbia factory in the capacity of assistant superintendent. He will have charge of the test department and also several others.

M. F. Todd, formerly connected with the sales department of the Regal Motor Sales Company, Detroit, has been transferred to the Cleveland branch and will have charge of the sales of the Regal car in the State of Ohio.

C. M. Halstead, formerly connected with a wire concern at Beaver Falls, Pa., has taken the management of the Auto Company garage at Akron, succeeding Andy Auble and Fred Woods, who acquired a garage in Cleveland.

Starr Burdick, for several years factory and sales manager of the Spicer Manufacturing Company, of Plainfield, N. J., has resigned his position and is about to embark in a new enterprise.

Lee E. Horton, formerly Cleveland Morgan & Wright manager, has accepted a position with the Fisk Rubber Company, and will have charge of the Cleveland sales for that company.

Charles L. F. Wieber, who two years ago became a member of the Rauch & Lang Company, of Cleveland, has been chosen manager of the factory and financial head of the company.

R. E. Olds, president of the Reo Motor Car Company, Lansing, Mich.

WITH THE AGENCIES

Even actors and actresses are getting the motoring fever. The picture shows Harry Lauder, the famous Scotch comedian, with his wife in their Hudson

Under the name of the United Auto Supply Stores Company, a new automobile supply house has been opened at 1693 Broadway. This branch is in charge of John Wooster, who bears the title of New York manager. From Mr. Wooster it was learned that this company has been recently incorporated to open up general supply and tire stores in the leading cities throughout the country.

The Firestone Tire & Rubber Company announces the establishment of the following new distributing agencies for Firestone tires and demountable rims: Central City Rubber Company, 129 E. Water St., Syracuse, N. Y.; Shuler Rubber & Supply Company, 345 Baronne St., New Orleans, La.; Chesapeake Tire & Rubber Company, 202 St. Paul St., Baltimore.

A movement is on foot by local interests to bring to Hartford, Conn., a British concern engaged in the manufacture of automobile parts. There are many available sites, and it is hoped that the prospective producers will locate here. The local board of trade offers every encouragement to automobile industries.

The Regal has been placed for Wisconsin with the Franklin Automobile & Supply Company, of Milwaukee. It was formerly distributed by the Grove Automobile Company, agents for the Jackson and Fuller.

Frank Briscoe, president of Briscoe Mfg. Company, and Brush Runabout Company

It is said that at the conference of the distributing agents of the De Tamble line held in Chicago on February 11, through concessions made by the agents and the factory, it would be possible to reduce the price of the De Tamble 34-horsepower car from $1400 to $1250.

The Great Western Automobile Company has closed contracts for the sale of Great Western "30" cars with the E. W. Clark Motor Company, Fond du Lac, Wisconsin; W. F. Huebner, Arrowsmith, Ill., and the Glide Automobile Company of Indianapolis, Ind.

The Columbus Buggy Company, of Columbus, Ohio, recently shipped its first carload of 1910 gasoline cars to the California Auto Company, of Los Angeles, the distributing agency for Southern California.

C. M. Logan, formerly with the Cleveland branch of the Olds Motor Works, has secured the agency for Pope-Hartford cars. Mr. Logan's territory includes all of Ohio except Cincinnati.

It is said that the British firm of Napier Motors will establish United States agencies with those who can add the British-built six-cylinder Napier to their present business.

The Eclipse Motor Car Company, of Columbus, O., has taken the Central Ohio agency for the Krit, manufactured in Detroit. The demonstrator is expected soon.

The Ohio Automobile Company, Dayton, O., has been appointed State distributor for the Springfield Car, made by the Springfield Motor Car Company, Springfield, Ill.

At Youngstown, O., Smith, Morgan & Company have taken possession of their new salesroom on East Boardman street. The Buick line will be handled.

The Ross Motor Company, of Superior, Wis., has secured the local agency for Overland automobiles, in addition to a number of other lines already handled.

The Krouse Motor Car Company, 317-321 North Broad street, has acquired the Philadelphia sales rights for the Halladay car.

W. W. Lester has taken the Hartford agency for the Brush runabout. This is the first appearance of that car in this city.

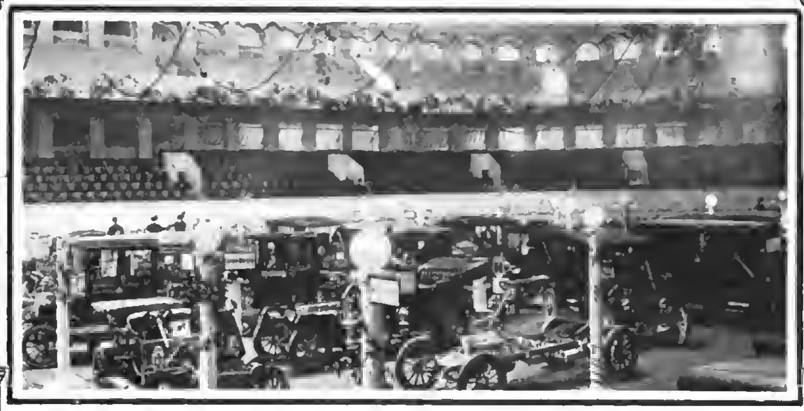
The Grout Automobile Company, of Orange, Mass., has opened a Boston branch in the Motor Mart. E. P. Forbes is in charge.

Harry S. Moore, Cleveland agent for the Stoddard-Dayton and National, has taken the agency for the Courier.

The R. A. C. is an addition to the line carried by the Hickman-Lauson Diener Company, of Milwaukee, Wis.

The Overland district agency for Rice Lake, Wis., has been placed with T. H. Field, of that city.

E. H. Peshak, of Beaver Dam, Wis., has obtained the district agency for the Oakland.



REALM OF THE MAKERS

View of one corner of the Milwaukee Show, showing the decorations, seats in the gallery, and in the foreground the Locomobile and Haynes exhibits

The Central City Rubber Company, 131 East Water street, Hanover Square, Syracuse, N. Y., is having extensive improvements made to its store, which when completed will give the firm one of the finest retail salesrooms for the handling of everything for the autoist but the automobile that there is in all central New York. These improvements include a new all-glass store front, modernized salesrooms on the main floor and in the basement, besides new concrete sidewalks of modern construction with sidewalk elevator.

Although it is about six weeks since one of the large factory buildings of the Racine Manufacturing Co. was destroyed by fire, it remains that they have resumed operations in practically the same proportions as before, delivering finished products to their patrons as usual. This concern has equipped a new factory building which was completed just prior to the fire.

At the recent automobile show in Portland, Ore., a Franklin, the only air-cooled automobile exhibited, was given an extreme test in a 72-hour non-stop run. This ended without a sign of overheating, nor was any replacement of parts necessary during the three days of continuous work.

The Winton Motor Carriage Company has purchased 89 feet on the east side of Woodward avenue, near Warren, in Detroit, and is planning to erect a modern showroom on the site.

J. G. Perin, chief engineer, the Lozier Motor Company, Plattsburg, N. Y., and Detroit, Mich.

The Mitchell-Lewis Motor Company, of Racine, Wis., is making every provision for the comfort and convenience of its thousands of employees. The latest innovation is a hospital corps. A Mitchell is stationed at the plant at all times day and night ready to transport an injured man to a physician's office or hospital, as occasion requires.

The Goshen Buggy Top Company, of South Bend, Ind., has decided to equip its factory for the manufacture of automobile tops. The necessary machinery has been ordered, and when installed an additional force of men will be put to work.

The Sebring Motor Car Company, of Sebring, O., has completed its first car and will exhibit it at the annual show to be held in Cleveland, February 19-26. The Sebring is of the six-cylinder type and has a horsepower rating of forty.

The first regular allotment of Model S Mitchells to be sent to dealers, left the plant of the Mitchell-Lewis Motor Co., at Racine, Wis., last week. The Model S is the new six-cylinder listed at $2,000.

The Gardner Wheel Company, Indianapolis, has put in complete equipment for the manufacture of automobile wheels. Indiana hickory, which has long been the standard wood for this purpose, will be used.

The Star Rubber Company, of Akron, Ohio, has announced its intention of manufacturing automobile tires on a large scale. A large addition to its present plant will be erected within a short time.

The E-M-F people say that they set a record of 20 cars a day sold at the recent Philadelphia Show. This company exhibited a full line in their spacious showrooms on Chestnut street, that city.

The McCord Machine Company, Philadelphia, Pa., formerly located at 1621-4 Brandywine street, has removed to 2231 Brandywine street, where it has a first-class establishment.

The B. C. K. Motor Car Company, of Philadelphia, has just completed new buildings at its Bath, N. Y., plant, and machinery, approximately $32,000 worth, has been installed.

W. L. Eslein, traveling representative of the Wisconsin Motor Car Company, of Janesville, Wis., making the "Wisco," is now working in northern Wisconsin placing agencies.

The Pope Manufacturing Company, of Hartford, Conn., has delivered to the Denver fire department a combination chemical and hose wagon of the usual type.

The Compressed Gas Tank Company has succeeded the Puritan Gas Tank Company, and will continue to build these latter tanks at Canton, Mass.

Beginning February 1, the price of the Hupmobile was raised $50, and in the future this little car will sell for $800.

NEWS IN GENERAL

Scene in Philadelphia during the big strike, showing the White steamer used by the police to charge through the crowds and thus disperse them

Boston now has over eighty purely automobile houses, representing over one hundred different makes of cars. There are about a dozen makes of commercial motor vehicles represented, and the rest are pleasure vehicles. This is a marked increase over last year, both in the number of establishments and in cars represented. The cars include practically every well-known make of American machine, and within the past few months not a few of the newer cars have obtained agencies here. There are a half-dozen agencies or branches for the sale of foreign cars. Of the total number of establishments, seventeen are branch houses and the remainder agencies. Only one or two new branches have been opened the past year, the tendency being apparently more strongly in the direction of agencies than toward branches. The local trade is in excellent condition, and long before the deliveries of 1910 models ceases a new record for sales will have been established, all previous marks at show time already having been surpassed.

Paul Hardin, of Chester, S. C., is out with a challenge that has set the auto gossips busy in at least four of his neighboring counties. A few days ago W. C. Thomson agreed to buy a two-cylinder 1910 Reo on condition that it would be run under its own power from Chester to Bullock's Creek, S. C., by Hardin. Thomson lives twenty miles from the nearest county seat, where the roads are of a heavy red clay, which at this time of the year are impassable for a wagon in many places. The long trip was successfully made by Hardin, though the road was lost twice. Thomson is now the proud owner of the car and Hardin offers to bet any local dealer of a car that cost twice the price of the 1910 two-cylinder Reo, one car against the other, that he cannot follow the Reo in a cross-country run to Bullock's Creek, or over any other similar roads within fifty miles of Chester. The challenge has as yet not been accepted.

With the advent of open weather will come the installation of the first suburban auto bus service ever operated in Philadelphia County, Pennsylvania. Citizens living along Bustleton Pike, between Frankford and Somerton, have requested the rapid transit company in Philadelphia to establish a line along the Pike. Failing in this, a number of citizens decided to form a company, with a capital of $15,000, to be used for the installation of an auto bus line. Three cars, with a capacity of fourteen passengers each, have been bought.

The Aero Club of America has secured one of the finest suites of offices in the Engineering Societies Building, 29 West Thirty-ninth Street, practically the last now available in that national headquarters of professional men devoted to engineering and mechanical pursuits. It is the home of twenty-five engineering bodies with some 30,000 members, every one of whom, by nature of his training and occupation, is interested in this latest development of mechanical arts.

A Cadillac roadster has been purchased by the Water Department of Wilmington, Del., at a cost of $1,700, for the use of the directors and officers of the department. This is the second branch of the city government to be so equipped, the street and sewer department having had a machine in use for some time. with great success.

A Webb automobile fire engine has been purchased by the Reliance Fire Company, of Wilmington, Del., at a cost of $8,500. The builders are to give it a thirty-day test before it is accepted by the purchaser. Several other companies are awaiting the result of this test before placing orders for machines.

Sheriff H. E. Frank, of Milwaukee, believes that it takes an automobile to catch an automobile, and has a 1910 Franklin touring car, with which he plans to capture speed law violators during the summer. The Sheriff will cover the Whitefish Bay road, one of Milwaukee's best automobile highways.

Carl G. Fisher, of Indianapolis, has divulged plans for an automobile row in that city, which will represent an aggregate expenditure of about $1,000,000. It is said that the ground has been purchased and plans drawn for the building.

The Pittsburgh Taximeter Company has been organized by Grant McCargo, Charles A. Blanchard and John W. Weibly to manufacture taximeters.

H. O. Smith, president of the Premier Motor M pany, Indianapolis

Independent Boston Show in the Former Art Museum, Where Parry, Lexington, Hupmobile, Mack, and Whiting Appeared

INDEPENDENTS SHOW AT ART MUSEUM

The old Art Museum in Copley Square, Boston, was turned over to the independents who failed to get space at the big show in Mechanics' Building, and the effort, while it is less pretentious than that of the trade association, attracted its measure of the patrons in Boston and vicinity. The location of the Art Museum is so thoroughly advantageous that every autoist in going to and from the railway trains at Back Bay had attention drawn to the independents' show by large and well-placed signs which are clearly depicted in the illustration here offered. The attendance is reported as encouraging in the extreme, and the independents who have the courage of their convictions feel justified in thus making what must be termed an ambitious effort.

Exhibitors at the independents' show were: Hupmobile, Lynn Automobile Company, Boston; Rainer, Rainier Company, Boston; Lexington, Nock Auto Company, Providence; Mack, the Manhattan Motor Truck Company, Boston; Parry, the Parry Company, Boston; Whiting, Flint Wagon Works, Flint, Mich.

AEROPLANE AND BIG CROWD AT PORTLAND

Portland, Me., Mar. 5—Portland's automobile show closed Saturday evening, and there had been a record-breaking attendance during the whole of the week. Not only were there large crowds during the afternoons and evenings, but the morning attendance was the largest ever known in the history of the five shows given in Portland. Before the end of the week, as some of the cars were late in arriving, it was estimated that fully $300,000 worth of automobiles had been placed on exhibition.

On Friday, the day before the show closed, an aeroplane of the Curtiss type arrived, and was exhibited in the basement of the Auditorium. It proved the center of attraction for the whole show, as hundreds of people went to the exposition just to see this. The flyer shown was the property of F. J. Tyler, of the Maxwell-Briscoe Company, and was especially loaned to the Portland show by the owner, who had purchased it at the Boston aero show.

MILWAUKEE SHOW FINANCIAL SUCCESS

Milwaukee, Wis., Mar. 7—It is conservatively estimated that nearly 100 cars were sold during motor show week in Milwaukee, to the aggregate value of $215,000. This includes sales made at the Milwaukee Automobile Club's second annual exposition in the Auditorium and by the fourteen independent dealers who held private shows in their garages. The Auditorium show's total attendance was 33,500. Of the profit, the exhibitors will receive 35 per cent., or 10 per cent. more than in 1909.

Twenty-six pleasure vehicles were shown for the first time at the Milwaukee show, the newcomers comprising more than 50 per cent. of the entire pleasure vehicle display. In the commercial section twelve makes were presented and Milwaukee's standing as a commercial vehicle manufacturing center was strikingly shown in this instance. In the motorcycle division six standard makes were represented, three being home products, while the accessory concerns represented numbered twenty-four.

The officers and board of directors of the Milwaukee Automobile Club who were largely responsible for the pronounced success of the exhibition, even in spite of many obstacles placed in their way by the so-called insurgent dealers, are as follows: President, Clarke S. Drake; vice-president, Geo. A. West; secretary, Arthur C. Brenckle; treasurer, Lee A. Dearholt; M. C. Moore, C. Schlotka, O. F. Fischedick, Dr. Louis Fuldner, Wm. H. Pipkorn, J. E. Farber, Faustin Prinz, J. F. Schreiber.

FOUR MORE SELDEN PATENT LICENSEES

Seventy-six makes of American and foreign cars now appear on the official list of Selden Patent licensees.

Those appearing on the list for the first time are: Flandrau Motor Car Co., of New York City, licensed to import and sell in this country the Brasier car; W. H. McIntyre Co., of Auburn, Ind., making the McIntyre car, and Simplex Motor Car Co., of Mishawaka, Ind., making the Amplex car, formerly known as the American Simplex, and Great Western Automobile Company, Peru, Ind., making the Great Western car.

CHICAGO SHOW FOR 1911 WILL RUN THIRTEEN DAYS

THE Chicago Show of 1911 will extend over a period of thirteen days, exclusive of Sundays, instead of seven days. This was decided upon at a meeting of the executive committee of the National Association of Automobile Manufacturers, Inc., held on Wednesday afternoon, having been recommended by the show committee and the general manager.

The amount of space at the command of the Chicago show management is greater than at any other show held in the United States, but this year, despite this fact, the application of over 40 makers of automobiles and 200 makers of accessories were refused on account of lack of space, while the makers of commercial vehicles were not even considered.

It has not yet been decided how the exhibits will be divided. It may be, and it is indeed probable, that the space allotted to automobile exhibits during the first week will be given exclusively to members of the National Association of Automobile Manufacturers, as founders, but whether pleasure cars and commercial vehicles will be mixed during the second week is a matter for future consideration, and is, perhaps, dependent to some considerable extent on the amount of interest taken in the exhibition by commercial vehicle makers.

Another branch requiring careful consideration is the motorcycle department, confined heretofore to about 25 spaces, but demanding, through the Motor Cycle Manufacturers' Association, at least four times as much space as it has been possible heretofore for the management to furnish.

The show will open on Saturday, January 28, and the first section will continue until and including Saturday, February 4. The floor will be entirely cleared of cars that night, and the buildings will reopen on Monday afternoon, February 6, for the second section of the show, continuing until and including Saturday, February 11.

Present at the meeting on Wednesday afternoon were: L. H. Kittredge, W. T. White, Thomas Henderson, W. E. Metzger, S. T. Davis, Jr., S. D. Waldon, C. C. Hildebrand, H. O. Smith, A. L. Pope, Benjamin Briscoe, R. D. Chapin, C. G. Stoddard and S. A. Miles, general manager.

The report of the late Chicago show showed that there had been 1,548 dealers in attendance, and that the total attendance, including the public, dealers, exhibitors and their attendants, exceeded 200,000 people, and probably reached nearer 220,000.

The committee further adopted the following resolution: "Resolved that, in the opinion of this executive committee, the interests of automobile manufacturers are well and sufficiently served by the national shows held annually at New York and Chicago, and that experience has indicated that an addition to the number of shows would be undesirable.

"Resolved further, that the National Association of Automobile Manufacturers, Inc., will sanction, during the twelve months following the date of this resolution, no shows other than the annual national shows at New York and Chicago."

The president nominated and the committee approved the appointment of the following standing committees for 1910: Membership—S. T. Davis, Jr., J. W. Gilson, C. C. Hildebrand. Legislative—W. R. Innis, Benjamin Briscoe, C. G. Stoddard. Good Roads—R. D. Chapin, S. D. Waldon, L. H. Kittredge. Show—W. E. Metzger, A. L. Pope, Thomas Henderson. Contest—H. O. Smith, W. T. White, W. E. Metzger. Auditing—Benjamin Briscoe, S. T. Davis, Jr., Charles Clifton. Traffic—A. L. Pope, W. R. Innis, C. C. Hildebrand.

ALBANY SHOW WINS AGAINST WEATHER

(*Continued from page 511.*)

Notwithstanding a bad snowstorm which started early in the evening—in fact before dark there was a mighty good attendance—all of which was paid as the management, original again, did not put out any paper to swell the first night's attendance.

The usual large number of manufacturers and accessory representatives are on every hand giving the show the appearance of first importance such as it warrants by its extreme excellence in every detail.

The list of exhibitors comprise:

Albany Garage Company, Peerless, Simplex, Studebaker, Palmer-Singer, Apperson, E-M-F and Flanders; Albany Hardware & Iron Company, auto supplies, sporting goods, launches and canoes; Albany Motor Car Company, Cadillac and Thomas; Albany Rubber Tire Company, Selden; Buick Motor Company, Buick, Welch-Pontiac, Welch-Detroit; B. A. Burtiss, American, Hurtis auto wind shield; Central Automobile Company, Knox, Hupmobile; Cox Brass Manufacturing Company, windshields and accessories; Thomas L. Davis & Company, Jenkins; William Daye, Matheson; Eureka Motor Car Company, Cutting; G. Feltman, Reading Standard and Emblem motorcycles; Franklin Auto Company, Franklin; James Goold Company, Marmon; J. A. P. Ketcham, Packard; John Kingsbury, special bodies, tops, etc.; Lansing & Morrison, Gramm-Logan trucks; Maxwell-Briscoe Albany Company, Maxwell, Columbia; Peter Murray, Inter-State; Mohawk Valley Auto Company, Oakland, Oldsmobile; Park Garage, Mitchell, Speedwell, Chadwick, Frayer-Miller; Patten & Almy, Cameron; C. Sutherland Ransom, Lozier, Stevens-Duryea, Mercer; Roy M. Robinson, Reo, Rainier; Rose & Kiernan, auto insurance; Wm. L. Schupp & Sons, Marion, Overland, Rapid trucks; Snyder Auto Bazaar, Velie, Stearns; Steefel Brothers, auto apparel; Troy and Albany Auto Exchange, Pierce-Arrow, Chalmers, Hudson; Troy Auto Improvement Co., Hupmobile, Koehler; Taylor Automobile Company, Locomobile; George W. Wait, Elmore; Walter Chain Mat Company, No-skid chains; C. F. Weeber Manufacturing Works, Ford, Haynes; J. B. Wilbur, Regal, Croxton-Keeton; Wright-Rye Motor Company, White, Jackson, Rambler, Atlas; Vrooman Brothers, Hupmobile, Regal, Elmore.

The committee in charge consists of Major Charles B. Staats, Captain William J. McKown, Captain Allan L. Reagan, Wm. J. Grounsell, Chauncey Hakes, C. Sutherland Ransom, W. K. Foskett, J. A. P. Ketcham, Dr. Edward G. Cox and James C. Fitzgerald.

OMAHA DEALERS HOLD A GOOD SHOW

OMAHA, NEB., Mar. 3—One of the most successful shows ever held in the West came to a close Saturday night. Omaha dealers are proud of the showing they were able to make, especially in the number of different cars; the Omaha exposition had but five less factories represented than that at Chicago. This exhibition, in the minds of the local dealers, has clearly demonstrated that Omaha is the real center of the automobile trade west of the Mississippi.

The show just closed is the fifth to be held by the Omaha dealers. When the first show was held there were but five dealers in the city, and they had to scour the country to secure cars enough to make a respectable showing in the big building. Considerable urging was necessary to persuade some of them to take the chance on renting the building. Now it is not a question of how to get cars to fill the building, but rather how to get in all those that want to exhibit.

The management of the Sioux City show was so impressed by the decorations at Omaha that it bought all the fixtures outright at half price, thus making a saving to themselves as well as to the Omaha management.

RUMOR INVOLVES MORGAN AND E-M-F

DETROIT, Mar. 9—Just as THE AUTOMOBILE is going to press a special wire from Detroit reaches the Editorial Office in which it is said "Morgan gets E-M-F for five million dollars." All efforts to verify this story proved futile, nor was it possible to obtain information bearing upon this subject from anyone who could be reached in the office of J. P. Morgan & Company. Walter E. Flanders, president and general manager of the E-M-F Company, left the Hotel Martinique, New York, yesterday morning ostensibly to visit the Boston Show. THE AUTOMOBILE was unable to reach him within the limited time available.

INDEX TO ADVERTISERS

VOL. XXII NEW YORK—THURSDAY, MARCH 17, 1910—CHICAGO No. 11

THE AUTOMOBILE

FIRE EQUIPMENT is valuable in proportion to its ability to spill water on a conflagration, but it is of the greatest possible advantage to start the spilling process at the earliest moment after the fire has been started. There are a hundred reasons why prompt action is more efficacious than would follow the use of a mass of equipment on a procrastinating basis. There is no possible way of determining the relations which must exist between the effort required to quench a fire after it is well under way, as compared with the lesser effort, when the work is promptly begun. It might even be looked upon as a wasted effort to discuss this phase of the problem, but if it is well understood, it is amazing that fire departments persist in adopting animal-drawn equipment, when the automobile situation is sufficiently well in hand to serve every need, besides offering the advantage of greater promptness in putting streams on fires.

It is not the purpose here to delve into the theory of fire fighting, unless superficially, and to the extent which will be necessary in order to emphasize the importance to be attached to promptness. It is conceded that a fire equipment should possess a certain vigorousness, but it is only a matter of a few days ago when the writer witnessed the burning to destruction of a building with the fire engines stuck in the mud within a block of the scene of action. The engines were big enough; they were designed to throw a sufficient stream of water to accomplish the purpose, but they were handicapped by their weight, the condition of the pavement, and the inability of the horses to make headway.

This extreme case will serve as the preliminary in a further illustration of the differences which are not always taken into account. Admitting that the equipment should have a certain ability, it must also be conceded that it must be mobile. It is just as necessary to be able to move with speed and a certain exactness in going to a fire as it is to be able to apply vigorous streams of water, and remembering that a fire may be most readily quenched if the streams are directed thereon at the propitious moment, it may be that speed of the apparatus en route has a greater measure of virtue than will be found in a large capacity pumping engine.

These very ideas lead up to a detail which is pretty generally overlooked by the City Fathers in their widsom; if it is a distinct advantage to move to a fire with speed and certainty, it will be almost equally advantageous to speed back again in order to be ready for any possible contingency which may arise. If the fire equipment is sufficiently mobile, and has the property which will make it efficacious, it will not only do its work quickly, due to a prompt start, but it will be back again at its station awaiting an alarm.

Without attempting to be exact, it might be within the bounds of reason to proclaim that a company, if it arrives on the scene of a fire within half the time as ordinarily taken will be able to do its work at one quarter of the loss which would result under the first conditions named, but if it does its work in half the time, it will be available to do other work the other half of the time, and conclusions may be drawn as follows:

(A) One half as much fire equipment will accomplish the given work.
(B) The fire loss will be reduced to one-quarter.

Municipalities are never justified in counting the cost of a fire department in dollars expended. It is necessary to consider the saving of life and property which is realized by utilizing an organization of this character. It makes no difference then, as to whether or not the automobile type of fire fighting equipment will cost more or less than the conventional (animal drawn) equipment, since at any price likely to be charged, the equipment will cost but a small percentage of the saving it will effect to the community.

It is not conceded that automobile fire-fighting equipment will be more expensive than the animal-drawn apparatus, for the reason that the very promptness with which streams may be applied to fires reflects the small time which would be taken in putting them out, and if the equipment will do the work in less time, less of it will have to be used in a given zone for fire protection. Entirely aside from the conditions as above enumerated, there is still another angle from the cost point of view, which amounts to a paramount issue.

It is the uniformed force which bears most heavily, financially, upon the community, and if it is true that automobile fire equipment would reduce this force numerically, if it might not be cut in half, the cost of maintenance will then be nearly halved, and the difference in money value will be sufficient to pay interest upon a vast amount of equipment, but the conditions are such that the increase in equipment would not have to be made.

Fig. 1—Horse and carriage formerly used by Chief Lally in the Borough of Brooklyn, New York City, with 141 square miles of territory to cover

ENLIGHTENED METHODS ARE MAKING SUBSTANTIAL HEADWAY

Despite the uproar which is frequently made by reluctant taxpayers, the automobile is making inroads in fire-fighting work, and it is only necessary to discuss the situation using some one illustration to bring out the point which it is desired to make. Take for illustration the Boroughs of Brooklyn and Queens in the City of New York. Deputy Chief Thomas Lally in charge, who answers to every second alarm, must cover over 141 square miles of territory. In the old days the work was done by the horse and carriage, as shown in Fig. 1; but it was obviously impossible for a general officer to be first at a fire in a territory so large if the fire happened to be in a remote district. As for covering two fires within a short time of each other, to do so with the horse and carriage was utterly impossible.

The first change from the old idea came with the purchasing of a 16-horsepower Locomobile, as shown in Fig. 2, and while the little car was a revelation to the department, and gave the utmost satisfaction, the fact remains that it was the smallest size of regular touring car as then made by the company, and it indicated quite comprehensively the attitude of the City Fathers who seem to count the cost of the individual automobile in dollars rather than the value of the service.

After two years of the most strenuous type of service it was decided that the 16-horsepower Locomobile should be put in good working order and held in reserve. Up to this time the horse and carriage were held in reserve, but the extraordinary value of the service rendered by the Locomobile made it impossible to consider the advisability of using a horse and carriage, even in a supernumerary capacity. The next move was in the nature of a distinct advance, resulting in the purchase of a 50-horsepower Berliet (Alco), as shown in Fig. 4. This car offers the extra advantage of increased weight, larger diameters of tires, more power, storage capacity for clothing and appurtenances, and the speed over cobblestone pavement, of which Brooklyn has some hundreds of miles, is considerably higher than that which was formerly realized.

The conditons in Brooklyn are such that the Deputy Chief in charge turns out for first alarms in the high-pressure zone, on the park slope and along the water front, and, as before stated,

Fig. 2—Sixteen-horsepower Locomobile which was purchased by the department to replace the horse and carriage shown in Fig. 1. and is still in use as a supernumerary

Fig. 3—Oldsmobile police patrol as used by the department at Lansing, Mich., with excellent results, illustrating the added advantage of automobiles in police departments

for every second alarm. A canvass of the situation indicates with reasonable accuracy that Chief Lally goes to at least one fire per day for every day in the year, and not counting departmental inspections, travels at least a distance of 10 miles per run. It will readily be observed that there is no possible animal-drawn vehicle which would be capable of making these long runs on any basis whatever.

In the old days, then, considering the exigencies of service, the general officer in command of the department rarely ever gave the fire fighters the benefit of his skill and experience, and it was even a question if district deputies went to all the fires within the confines of their own territory. It is probably true that battalion chiefs went to every fire, but it cannot be said of them that they arrived in time to be of maximum service.

It is of incalculable advantage if field officers are on the ground ahead of the engine companies, for then they will be in a position to determine as to the extent of the conflagration, locations of hydrants, characteristics of the structures, and will be enabled to determine as to the best plan of action, so that when the companies come up they may be instructed in accordance with a definite plan of action.

On divers occasions it was found that additional alarms should be sent in, and the general officer upon arriving, even ahead of the companies which respond to the first alarm, promptly sent in the additional alarms, which, according to judgment, would call out the requisite number of companies, and by so doing save much valuable time. In the old way, the second, third and fourth alarms were turned in successively upon the arrival of the respective commands, and frequently the Chief of the Department found the distance too great to permit of responding to anything but a third or fourth alarm.

Experience with the automobiles as used by general officers has been favorable, and in so many ways that fire equipment of the automobile type is expanding at a rapid rate, so that to-day it is possible to procure from reliable makers divers types of equipment. Fig. 5 represents a Knox type of a hose wagon, as used in the New York Fire Department. This wagon, in addition to affording a sufficiently large platform on which to lay down the hose, offers the special advantage of a high-pressure nozzle, mounted on a stand, and mechanically designed to swivel into any desired position. The wagon is of stout design, with a tool box located under the body at the rear, and facilities for the orderly placing of firemen's appurtenances, and such other contrivances as are used in this service.

A platform for the hose is much more efficacious than any form of reel thus far tried out, not only as respects the length of hose which can be carried, but from a point of view of speed when running a line at a fire. The reel idea has its awkward situations. The hose is likely to be tangled up on occasions, and the total length of hose which can be reeled on is variable, depending upon the care with which the work is done; but it must be appreciated that care suggests time, which must be taken. The bottom illustration, Fig. 11, shows a Knox type of hose wagon, which is devoted to the high-pressure service in the New York Fire Department, and it illustrates how the hose is carried on the platform. There have been many attempts to improve upon this plan, but nothing thus far seems to possess the inherent merit of this simple process. The center illustration of

Fig. 4—Berliet (Alco) fifty-horsepower touring car now used in the Borough of Brooklyn by Deputy Chief Lally to cover one hundred and forty-one square miles of territory

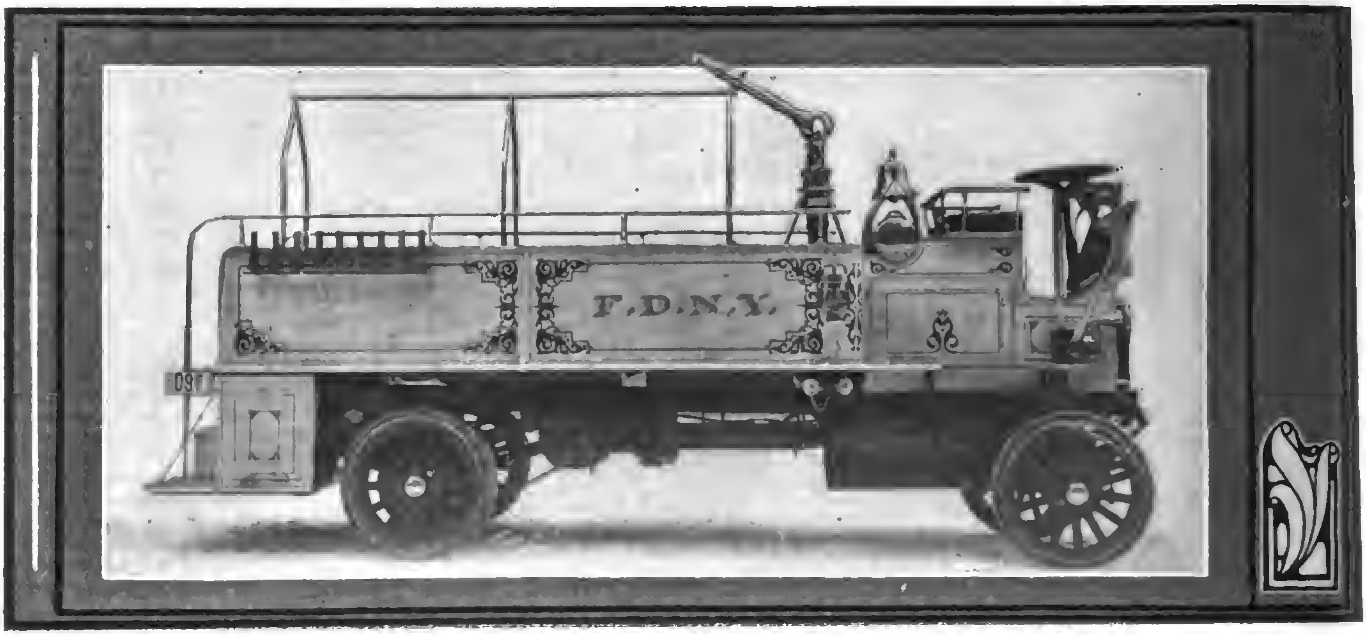


Fig. 5—Knox hose wagon, with swivel nozzle mounted in front, as used in the New York Fire Department

Fig. 11 shows a type of wagon as manufactured by Thomas B. Jeffery & Co., which serves for the first alarm work, having all the advantages of a chemical engine with a sufficient length of hose on a reel, and an ample supply of tools, as pikes, axes, etc., with seating capacity for the full company, and all the advantages of speed and endurance that are possible to obtain in connection with an automobile. The top illustration of the same figure presents a Pope-Hartford chemical equipment, which is used by the Bristol Fire Department, in connection with which provision is made, not only for the chemical apparatus and hose, but ladders as well.

Fig. 8 shows still another type of chemical as made by the Everitt-Flanders Company, the particular example heing in use at Taunton, Mass. In this case the Chief, with a limited crew, is enahled to go to a fire at top speed, and arriving on the scene in time frequently permits him to put out the fire hefore it assumes more than still alarm proportions. This car and the manner of its use offers a clinching argument in favor of prompt action.

Figs. 6, 7, 9 and 10 were taken by R. D. Lillie, especially for THE AUTOMOBLIE, at Lansing, Mich., and they represent the advanced methods which obtain in this progressive city. Fig. 6 shows the engine ready to go into action with hose, ladders, lamps, tools and a chemical auxiliary availahle for instant use. Fig. 9 is another view of the engine, which was taken in front of the fire house at Lansing, just as the same would appear ready

Fig. 6—Webb engine mounted on an Oldsmobile chassis as used at Lansing, Mich., showing the same going into action

to respond to an alarm. The Lansing chemical is shown in Fig. 10, and it has heen found to serve the purpose with high efficiency. The Chief's wagon is presented in Fig. 7. It is a runabout type of automobile, seating four, and is equipped with a chemical auxiliary, lanterns, tools and such other fire-fighting facilities as will he found of great advantage during the early stages of a fire.

The illustrations here offered cover the field in a general way, and to view them properly is to reach one conclusion of perhaps the greatest importance, from the point of view of fire-

Fig. 7—Chief Hugo R. Delfs, of the Lansing Fire Department, starting for a fire in the Oldsmobile

fighting. Promptness, which is said to be a virtue, is best exemplified in this class of work, and each one of the efforts made had this promptness as the underlying feature.

HIGH-PRESSURE SYSTEMS INCOMPLETE WITHOUT AUTOS

In the big cities, especially New York, modern "skyscrapers" so called, although they are said to be ahsolutely fireproof, must be protected from fires in adjacent huildings, and to whatever extent furnishings augment the fire risk, these buildings, some of them 30 stories high, can only be protected when a high-pressure system is employed, and even then promptness in applying streams has even greater virtue than would be true under ordinary conditions, due to the relative inaccessibility of the fires when started, and to the greater risk.

Fig. 8—E-M-F car used at Taunton, Mass., showing a chemical equipment on the running board; also the chief and company.

If a high-pressure system is available, which is true in New York City, all that is required is the requisite number of hose wagons, as illustrated in Fig. 5, and perhaps towers, although every building of importance within the metropolitan areas is provided with a system of standpipes. It was shown that the utilization of automobiles for field officers made it possible for them to go to every second alarm fire, even when the district covers more than 140 square miles, and to respond to first alarm fires within the solidly built-up districts. If it is advantageous to have the general officers so equipped that they will be enabled

Fig. 9—Webb engine in Oldsmobile at Lansing, Mich., standing in front of the fire house ready for instant use

to reach the scene of a fire first, this is equal to saying that the company should arrive soon enough to accept directions. It must be quite plain to any one that in the absence of fire equipment with which to proceed with the work, a general officer arriving on the scene can do but very little. It is the effort which counts above everything else, if the apparatus is not far behind, and if the streams can be applied forthwith.

In addition to the fire equipment proper, there are other situations to be taken into account, as, for illustration, the tenders. Then, there are the police patrol wagons, and hospital ambulances. It is of equal importance that these auxiliaries to a fire department, which is what they become under severe conditions, should be equipped to proceed with the utmost speed and certainty promptly upon call.

GASOLINE PUMPING ENGINES NOT SUFFICIENTLY DEVELOPED

One reason why automobile fire fighting equipment has not been adopted more readily, may be assigned to the absence of suitable headway in the design and production of pumping engines of the class which utilize gasoline motors as the source of power. This phase of the situation has been retarded for two reasons, one of which lies in the lack of enterprise of the makers of automobiles. They have confined their efforts to the class of cars which were most readily sold (pleasure automobiles), but they are beginning to realize that there is such a thing as overproduction, and they probably do appreciate the necessity of having a second line of defense. Commercial automobiles are rapidly supplanting horse-drawn vehicles in ordinary commercial pursuits, and as they develop along substantial lines, they will serve as the basis for special efforts, and with slight modification become available as the basis of design of fire-fighting equipment.

It is possible that public opinion will have to be aroused, to some extent, in the process of completing the evolution in favor of automobile equipment for fire departments, and unfortunately, the public is now divisible into two camps, the one of which realizes the stability of automobile equipment and the increased value which comes from its use; the other is bound down by inertia, which comes from lack of knowledge, hence absence of appreciation, and decries efforts at advancement.

Fig. 10—Chemical used at Lansing, Mich., showing an Oldsmobile chassis and every facility for quick work

FINIS

Graphical Determination of Transmission Loads

By L. C. FREEMAN

THE question of the selection of the proper sizes of ball-bearings for any given set of conditions is one that should receive the consideration of those most expert in their design and application. However, in change speed gear design, where the ratio between the diameters of the bearings and the diameters of the gears is small, the sizes of the bearings have so great an influence on the center distance of the shafts and the shape and outline of the casing that a change in the bearings from those originally laid out frequently necessitates the redesigning of the whole job. This, viewed from an economy standpoint, is a sheer waste of money that can be avoided and easily too. With an idea of aiding in this the following article was written.

This analysis is presented with the idea in view of determining the most important factor to be considered in the selection of the bearings, viz., the maximum loads imposed on them by the action of the gears. This will be found, and has been found in actual practice, to call for bearings of such size that a consideration of the other factors will not change them to an extent sufficient to cause a rearrangement of the entire mechanism. The other principal factors to be considered are the effects of unbalanced rotating parts, of brakes and sprags, of universal joints, of variations in the loads and the period of these variations. The latter will usually be found to permit a certain per cent. overload on reverse, sometimes 75 per cent. or over, due to its infrequent use.

The assumption then on which this analysis is based is that there are no forces acting on the bearings except those due to the gear pitch line loads.

The data required is the maximum turning moment, the diameter of the driving wheels, the load on the rear axle and the maximum coefficient of friction between the tires and the ground.

The method can best be illustrated by assuming the data and working out an actual example.

The motor develops 40 horsepower at 1,000 revolutions per minute. Spur gears, 6-8 pitch, having a pressure angle of 20 degrees. Bevel gears, 5 pitch, with 14 1-2 degrees pressure angle. The pressure on the bevels is assumed to act on the largest pitch diameter.

The arrangement of gears and numbers of teeth is shown in Fig. 1. Center distance of shafts, 4 1-2 in.

Gear	1—20 teeth,	6-8 pitch	3.333	pitch diameter
"	2—34 "	6-8 "	5.666	" "

"	8—18 "	6-8 "	3.000	" "
"	9—20 "	5 "	4.000	" "
"	10—60 "	5 "	12.000	" "

Note.—Paper read at semi-annual meeting of the Society of Automobile Engineers, Jan. 13, New York City.

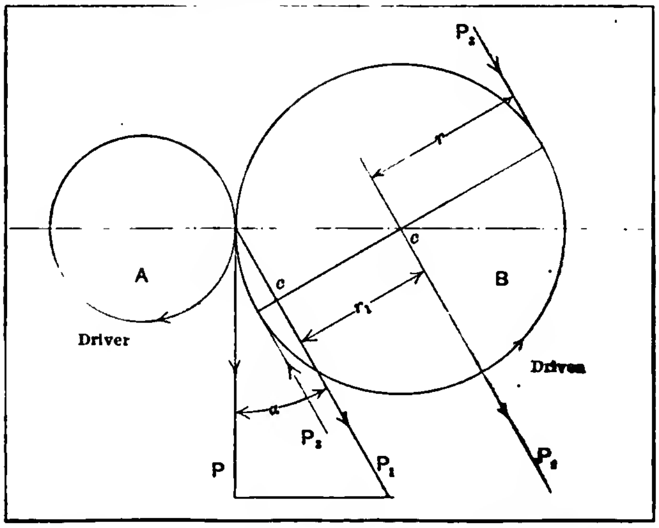

Fig. 2—Diagram of tangential pressure on gear teeth

Thirty-four-inch driving wheels with 2,500 pounds on the rear axle.

Sixty per cent. maximum coefficient of friction between the tires and the ground.

$$\text{Maximum turning moment is } \frac{\text{Horsepower} \times 33{,}000 \times 12}{N \times 2\pi} = pr.$$

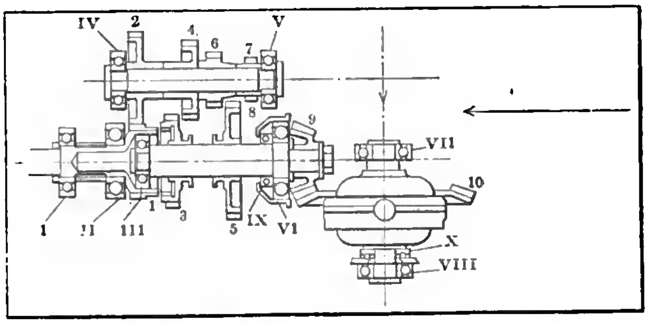

Fig. 1—Arrangement of gears in an actual example of a transmission

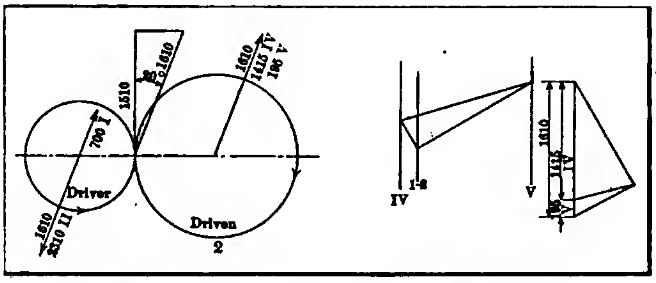


Figs. 4 and 5—End view of pitch circles showing notation

Where N = revolutions per minute;
r = radius of gear in inches;
p = tangential pressure on pitch line.

$$\frac{40 \times 33{,}000 \times 12}{1{,}000 \times 2\pi} = 2{,}520 \text{ inch-pounds.}$$

Pressure at largest pitch diameter of bevels necessary to slip

$$\text{wheels} = \frac{2{,}500 \times .60 \times 17}{6} = 4{,}250 \text{ pounds} = \text{maximum pitch line}$$

load on bevels. This is equivalent to a turning moment on the pinion shaft of 4,250 × 2 = 8,500 inch-pounds.

Turning Moment on Pinion Shaft

Pitch line load on constant mesh gears is

$$\frac{2{,}520}{1.666} = 1{,}510 \text{ pounds (gears 1 and 2) } 2{,}520 \text{ inch-pounds.}$$

Pitch line load on second speed gears is

$$\frac{1{,}510 \times 34}{26} = 1{,}970 \text{ pounds (gears 3 and 4) } 4{,}600 \text{ inch-pounds.}$$

Pitch line load on first speed gears is

$$\frac{1{,}510 \times 34}{18} = 2{,}850 \text{ pounds (gears 5 and 6) } 8{,}550 \text{ inch-pounds.}$$

Pitch line load on reverse gears is

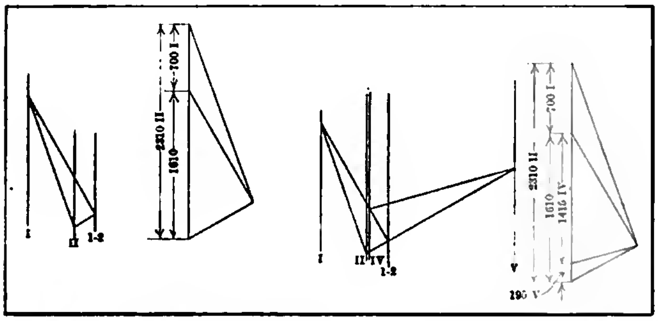
$$\frac{1{,}510 \times 34}{15} = 3{,}420 \text{ pounds (gears 5, 7 and 8) } 10{,}250 \text{ inch-pounds.}$$

But 8,500 inch-pounds is the maximum turning moment that can be applied to the pinion shaft without slipping the wheels.

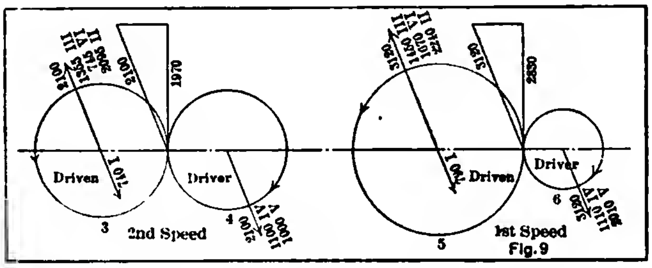
It will be seen that this is slightly less than that due to the first speed gear, and that the full power of the motor cannot be transmitted on reverse.

The pressure on the bearings of a pair of gears is equal to the pitch line tangential pressure multiplied by the secant of the pressure angle of the tooth, and the sum of the loads on the bearings of one gear is equal to the sum of the loads on the bearings of the other. That this is true may be seen by reference to Fig. 2.

A is the driver, B the driven gear, P the force acting tangent to the pitch circle, P_1 the pressure along the line of action, α the



Figs. 6 and 7—Graphical method of finding component forces acting



Figs. 8 and 9—Stress diagrams for gear pairs 3 and 4, 5 and 6

pressure angle, P_2 the pressure on the bearings parallel to P_1, and the forces P_2 form the resisting couple.

The moment of P about O equals the moment of P_1 about O.

$$P_1 = P \sec \alpha \qquad \frac{r}{r_1} = \frac{P_1}{P} \qquad Pr = P_1 r_1$$

$$r = r_1 \sec \alpha$$

The turning moment must be equal to the resisting moment, or $Pr = P_1 r_1 = 2 P_2 r$. (1). Taking moments about c,

$$\frac{P_2 (r + r_1) + P_2 (r - r_1)}{r_1} = P_2$$

$$\frac{2 P_2 r}{r_1} = P_2 \text{ from (1) } \frac{2 P_2 r}{r_1} = P_1 \therefore P_1 = P_2$$

Similarly for gear A

Fig. 3 is a skeleton diagram of Fig. 1, giving the distances between the centers of the gear pairs and bearings. All end views are taken in the direction of the arrows.

Lay off end views of the pitch circles of the gear pairs showing direction of rotation as in Fig. 4, which represents the constant mesh gears 1 and 2. Normal to the center line lay off the pitch line tangential pressure to scale, and consider it as one of two components of the pressure along the line of action, the other being parallel to the center line of the gear pairs.

This pressure along the line of action is equal to the sum of the pressures on the bearings of gear 2 and to the sum of the pressures on the bearings of gear I, and for each shaft must be resolved into two parallel components acting at the centers of the bearings. These will be inversely proportional to the distances from the centers of the bearings to the centers of the gear faces.

The graphical method of finding these components is exactly the same as that for finding the reactions of the supports of a beam with a concentrated load. The solution for gear 2 is shown in Fig. 5, where the pressure on bearing IV is found to be 1,415 pounds and on bearing V 195 pounds.

In Fig. 6, the solution for gear I, it will be noticed that the pressure on bearing II is equal to the sum of the pressure on bearing I and the pressure on the line of action of gear I; that the pressure on bearing I acts in the opposite direction from that on bearing II, and that there is no pressure on bearing III from this gear pair.

These bearing pressures are then transferred to the end views of the gear pairs as in Fig. 4, thus determining their direction. Fig. 4 then shows the magnitude and direction of the pressures on all the bearings affected by the action of gears 1 and 2. Figs. 5 and 6 may be combined as in Fig. 7, thus reducing the number of measurements to be made, and consequently the liability of error.

Figs. 8 and 9 are the end views of gear pairs 3 and 4, and 5 and 6, respectively. Figs. 10 and 11 are the end views of gears 5, 7 and 8, Fig. 10 showing the reverse idler above the other two gears, and Fig. 11 shows it below. If, because of structural difficulties, the reverse can be placed in but one of these positions, the other, of course, will not be considered.

It will be noticed that the pitch line load on the first speed and reverse gears in Figs. 9, 10 and 11 is taken as 2,830 pounds instead of 2,850 pounds for the first speed, and 3,420 pounds for the reverse, which we found by figuring from the motor torque. However, we have seen that 8,500 inch-pounds is the maximum turning moment that can be applied to the pinion shaft without slipping the wheels. The radius of gear 6 is 3 inches and

$$\frac{8{,}500}{3} = 2{,}830 \text{ pounds, which is the maximum pitch line load on}$$

gear 6.

Although the pitch line loads on the first speed and reverse gears are the same, the point of application of the load is in a different plane, and so it is necessary to construct the equilibrium and vector diagrams for each case. The bearing load distribution is the same for Fig. 11 as for Fig. 10, the only difference between the two cases being in the direction of the pressures.

Fig. 12 is the load distribution diagram of Fig. 8. The pressure on the line of action, 2,100 pounds, is resolved into the two parallel components 1,100 and 1,000 pounds acting on bearings IV and V respectively, and also into the components of 1,355 pounds and 745 pounds acting respectively on bearings III and VI. The

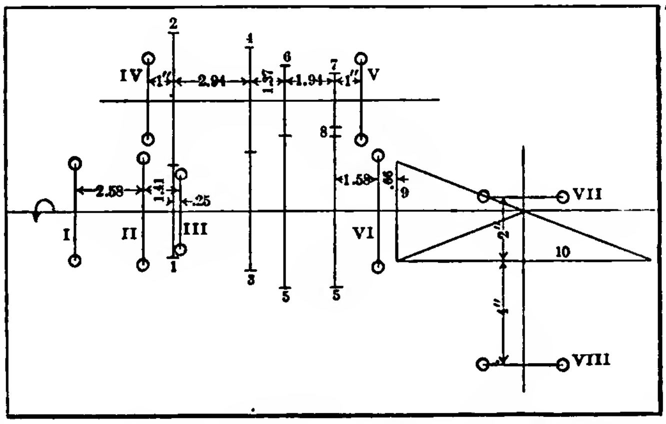


Fig. 3—Diagrammatic layout of transmission giving distances

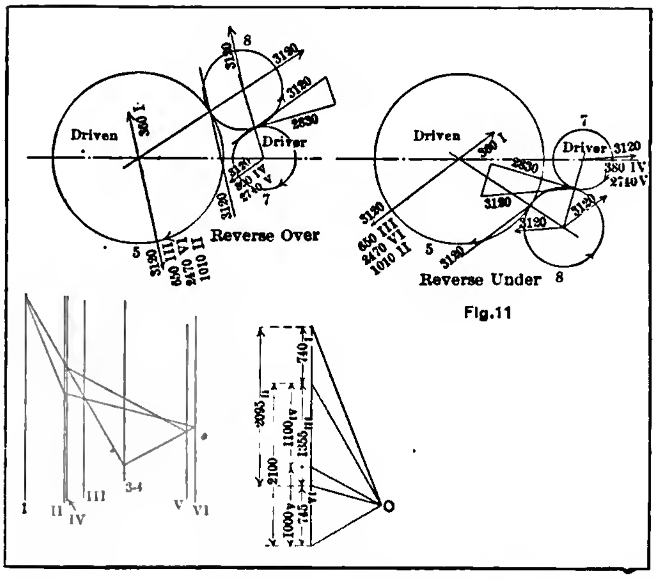

Figs. 10, 11 and 12—Layout and stress diagrams for gears 5, 7 and 8

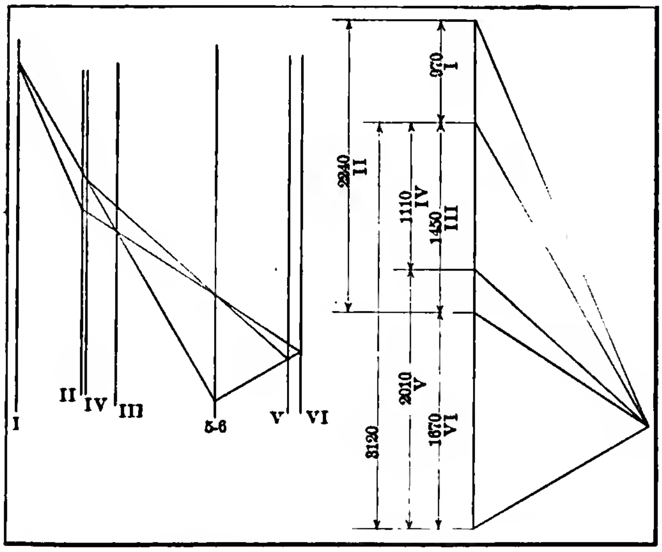

Fig. 13—Load distribution diagram for first speed gears

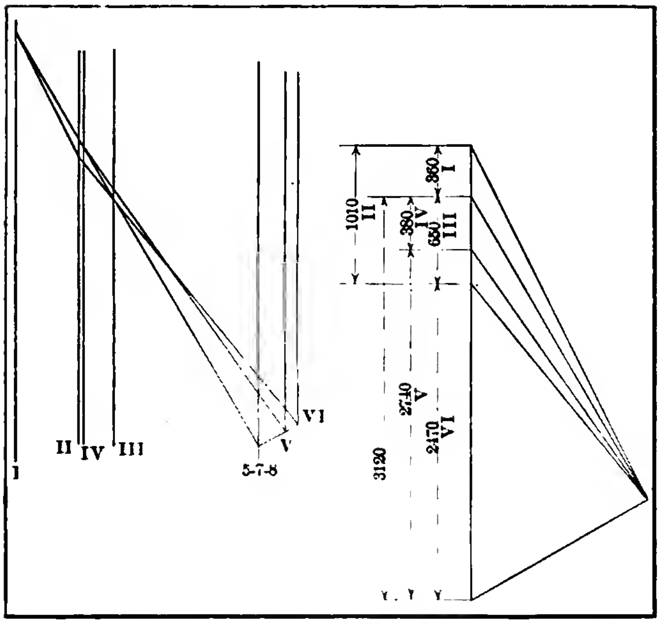

Fig. 14—Load distribution diagram for reverse gears

load of 1,355 pounds on III is then resolved into loads of 740 pounds on I and 2,095 pounds on II.

Figs. 13 and 14 are the load distribution diagrams for first speed and reverse, respectively.

The general equation for thrust on a bevel gear pair is:

$T = P \tan \alpha \sin \beta$, where

T = thrust.

P = tangential pressure on pitch line.

α = pressure angle.

β = pitch angle of gear.

The equation for radial load is:

$$L = \sqrt{P^2 + (P \tan \alpha \cos \beta)^2}$$

where L = radial load.

These mathematical expressions do not show the direction of the forces acting, and as these have to be taken into consideration, the graphical method which gives a complete solution is used. This is in fact the principal reason for the use of the graphical method throughout this analysis.

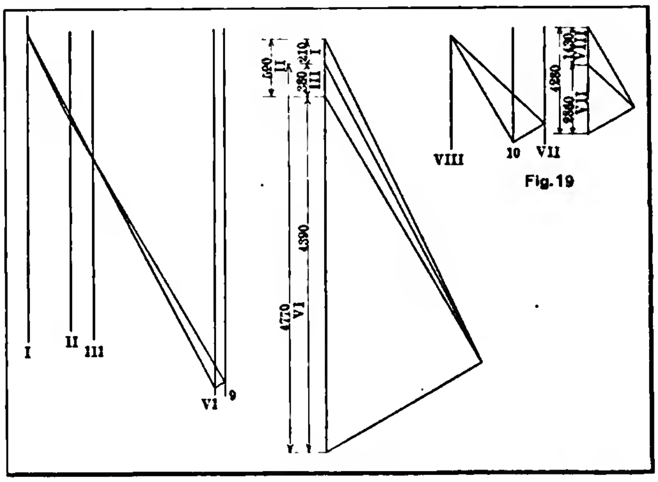
Notation for Fig. 15.

A = Driving pinion.
B = Driven gear.
α = Pressure angle.
β_1 = Pitch angle of gear.
β = Pitch angle of pinion.
P = Tangential pressure on pitch line.
P_1 = Pressure on line of action.
P_2 = Thrust component of P_1.
P_3 = Pinion thrust.
P_4 = Gear thrust.
P_5 = Pinion radial component of P_2.
—— 1,510 pounds (gears 1 and 2) 2,520 inch-pounds.
P_6 = Gear radial component of P_2.
P_7 = Pinion radial load.
P_8 = Gear radial load.

The black arrows indicate forces acting on the gear, and the light arrows the forces acting on the pinion. If the three large triangles, P, P_1, P_2; P, P_7, P_6, and P, P_8, P_6, were revolved downwardly about their shortest sides as an axis until in planes at right angles to the paper, they would represent the magnitude and direction of the forces acting in these planes or in parallel planes. The triangles P_2, P_3, P_4 and P_2, P_5, P_6 represent the magnitude and direction of the forces acting in the plane of the paper.

P is laid off on the common element of the two pitch cones. P_1 on the line of pressure and P_2 drawn normally to P precisely as for spur gears.

Care must be taken in determining on which side of P P_1 shall lie. This point is brought out more clearly by reference to the analogous spur gear diagrams in Fig. 16, in which it is seen that for the four cases the line of pressure has but two possible inclinations.



Figs. 18 and 19—Load distribution diagram for all bearings

P_2 is then resolved into two components, P_3 acting axially and P_5 radially on the pinion, and also into P_4 acting axially, and P_6 radially on the gear. Then the radial loads on the gear are P_6 acting in the plane of the paper and P acting vertically to the plane of the paper, and their resultant is P_8. Similarly the resultant of P_5 and P is P_7. These radial loads are then transferred to the end views of the gears as shown.

Careful attention should be paid to the direction of the forces and reactions, remembering that the direction of the resultant must be opposite to that of its components, and that the end views of the gears must be drawn on the same side as the force diagram. Thus, if the end of gear B was drawn on the opposite side (shown by the dotted lines) of the gear, the resultant radial load could not be directly transferred from the force diagram, but would have the apparent direction shown.

If in Fig. 15 the angle between the shafts become 90 degrees.

$$\beta + \beta^1 = 90 \text{ degrees.}$$
$$P_3 = P_6.$$
$$P_4 = P_5, \text{ as in Fig. 17,}$$

while if the shafts are parallel

$$\beta = \beta^1 = O.$$
$$P_2 = P_5 = P_6$$
$$P_3 = P_4 = O$$
$$P_1 = P_7 = P_8$$

which will be seen to be identical with the spur gear diagrams, in which the thrust is O and the radial load on both gears equals P_1.

We have seen that 4,250 pounds is the maximum pitch line load on the bevels, so that in Fig. 17 P equals 4,250 pounds and the radial and thrust loads are found to be as follows:

Pinion radial, 4,390 pounds.
Pinion thrust, 345 pounds.
Gear radial, 4,290 pounds.
Gear thrust, 1,035 pounds.

The load distribution on the bearings is shown in Fig. 18 for I, II, III, VI, and in Fig. 19, for VII, VIII.

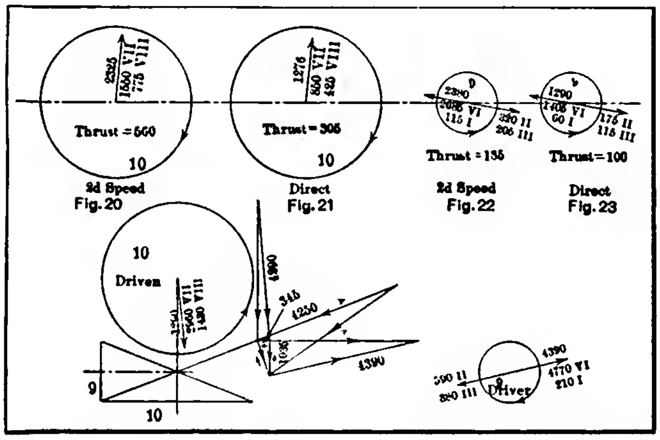
The maximum pitch line load of 4,250 pounds on the bevels occurs only on first speed and reverse. This pressure, on second speed, is equal to the tangential pressure on gear 3 times the ratio of the diameter of gear 3 to the diameter of gear 9.

$$1{,}970 \times \frac{4{,}666}{4} = 2{,}300 \text{ pounds}$$

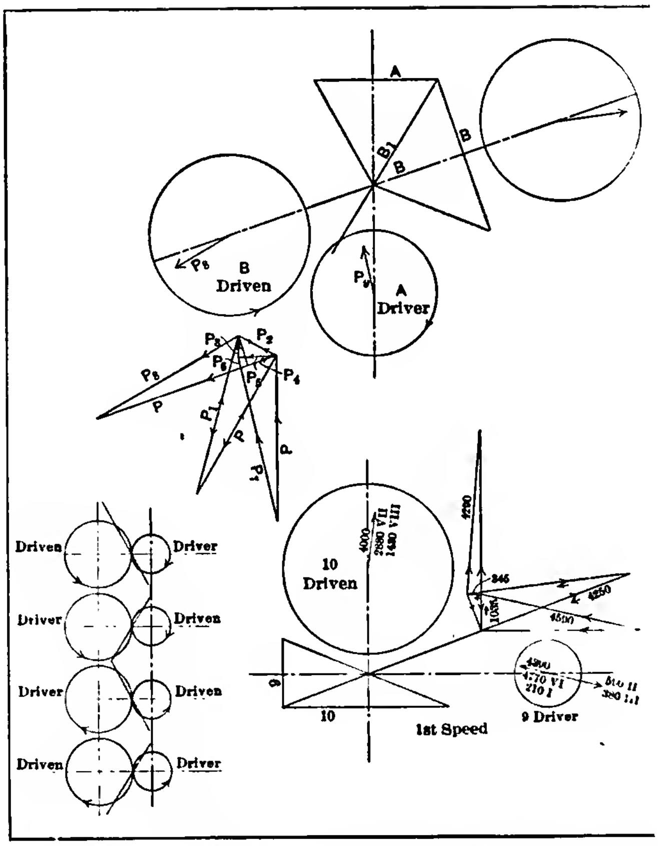
and on direct is equal to the turning moment of the motor divided by the radius of gear 9.

$$\frac{2{,}520}{.2} = 1{,}260 \text{ pounds.}$$

The bearing pressures due to the action of the bevels are proportional to the bevel gear pitch line tangential pressure, and as the forces act in the same direction they can be calculated and plotted from Fig. 17.



Figs. 20, 21, 22, 23 and 24—Differing pressures with varying speeds



Figs. 15, 16 and 17—Variation in thrust and radial load with angle

	DIRECT	2D SPEED	1ST SPEED	REVERSE OVER	REVERSE UNDER
I	60	560	600	840	900
II	175	1730	1880	2620	2860
III	115	1200	1150	270	590

VII	850	1550	2860	2860	2860
VIII	425	775	1430	1430	1430
Pinion Thrust	100	185	345	345	345
Gear Thrust	305	560	1035	1035	1035

Fig. 25—Tabular summation of all loads on each bearing

Fig. 20 shows the pressures thus obtained for VII and VIII, on second speed, and Fig. 21, the same bearings on direct. Figs. 22 and 23 show the loads on bearings, I, II, III, VI, for second speed and direct respectively.

The load distribution is quantitatively the same for reverse as for first speed, but as the direction of the forces are different, a new diagram must be made for this case, as in Fig. 24.

Figs. 25 is a further analysis of Figs. 4, 8, 9, 10, 11, 17, 21, 22, 23, 24, by means of which the summation of all the loads acting on each bearing on each speed is determined. It will be noticed that bearing I on direct is affected by the bevels only, while on second speed it has loads imposed on it by the action of three different sets of gears; the constant mesh, second speed, and bevels. The resultants are found for each case and tabulated as in Fig. 25. Knowing the percentage of overload on reverse allowable for the type of bearing used, this will form a sound basis for the design of the gear.

From a close inspection of this table and the values given therein, which are the result of some involved figuring, the student of such matters will find a great deal to interest him.

How Efficient Lubrication Reduces Maintenance

LUBRICATION presents to-day the same fertile field for thought or experimentation as it did in 1832, 78 years ago, when General Morin, the famous French engineer, first gave the world the now comparatively well-known laws pertaining to that subject. From that day to this, little has been done of a constructive nature, the worthy attempts in that field being more destructive or spasmodic. Instead of clarifying the situation, this later work has served to cloud the real issue, and even to-day, instead of a world-wide propaganda of education, the lubricating men are more likely to be found engaged in purely commercial efforts.

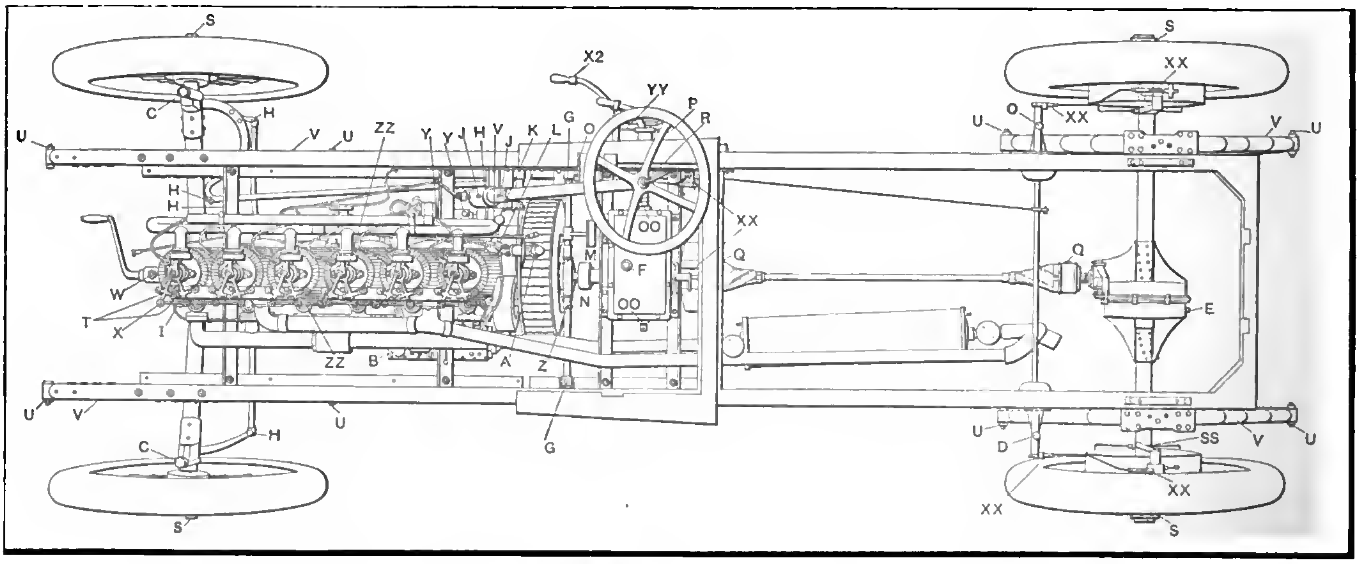
When a man buys a building, he insures it, engages a caretaker, looks after painting, repairs and other things, so as to keep the factor of depreciation down to the very lowest possible point. At that, the amount set aside or figured for replacement is on the basis of a shorter term of years than this type of building has been known to last. So, it happens that finally a time comes when an amount has been set aside sufficient to replace the old building with a new one, and still the old building stands and is of use. In short, due to forethought and care, the building is available for several years' use or to produce income without a corresponding outlay.

Why then is it that the same care and forethought is not applied to the purchase of some other class of realty, as, for instance, an automobile? Insurance, certainly; painting, surely; repairs, always; but care of the working parts, seldom. Under the heading of care should be included the most important item of all and by the same token, the most neglected, that of lubrication. By this is meant proper and complete lubrication.

This is a matter which may be capitalized in dollars and cents so as to show the owner of an automobile just what to expect for each degree of outlay of time and money in lubricants and lubrication.

Thus, at the bottom of this page is shown a lubrication diagram of a modern automobile. In this, the points to be oiled or greased are indicated by means of arrows pointing to them, while each one is lettered. The frequency of lubrication may be tabulated referring to the points indicated and using the letters as there shown. It has in fact been done on the opposite page, although at a casual glance, it is not apparent. The various points needing lubrication have been gathered into a list and a value, or length of time which each part may run without lubrication renewal, assigned to each. This gives when plotted a line of frequency of lubrication, or curve of necessity. Necessity because if not heeded or avoided, rapid depreciation, or even accident, may be the ultimate if not immediate outcome. Now since experts differ and differ somewhat radically as to the exact mileage from any one part before a renewal of lubricant is necessary, there is some excuse for the liberties taken with existing figures, one maker's table being given on a later page.

These renewals being plotted give a curve from these needing lubricant attention at all times, that is to say, practically continuously up to those others, like rod ends, which need scant attention in the ordinary course of running. As opposed to this, another curve is superimposed in which the work done by each part is given a relative importance value, and the whole of these values plotted to form a curve. Since the number of rotations per unit of time varies from the engine through all connecting and interrelated parts back to the wheels, as well as in the parts which never make a full turn, but rotate say 45 degrees once in awhile, it is apparent that the importance varies with these turns. Probably the most important part, the crankshaft, has the highest



Lubrication Diagram of Franklin Automobiles, Shown to Illustrate Number of Points Needing Frequent Lubrication

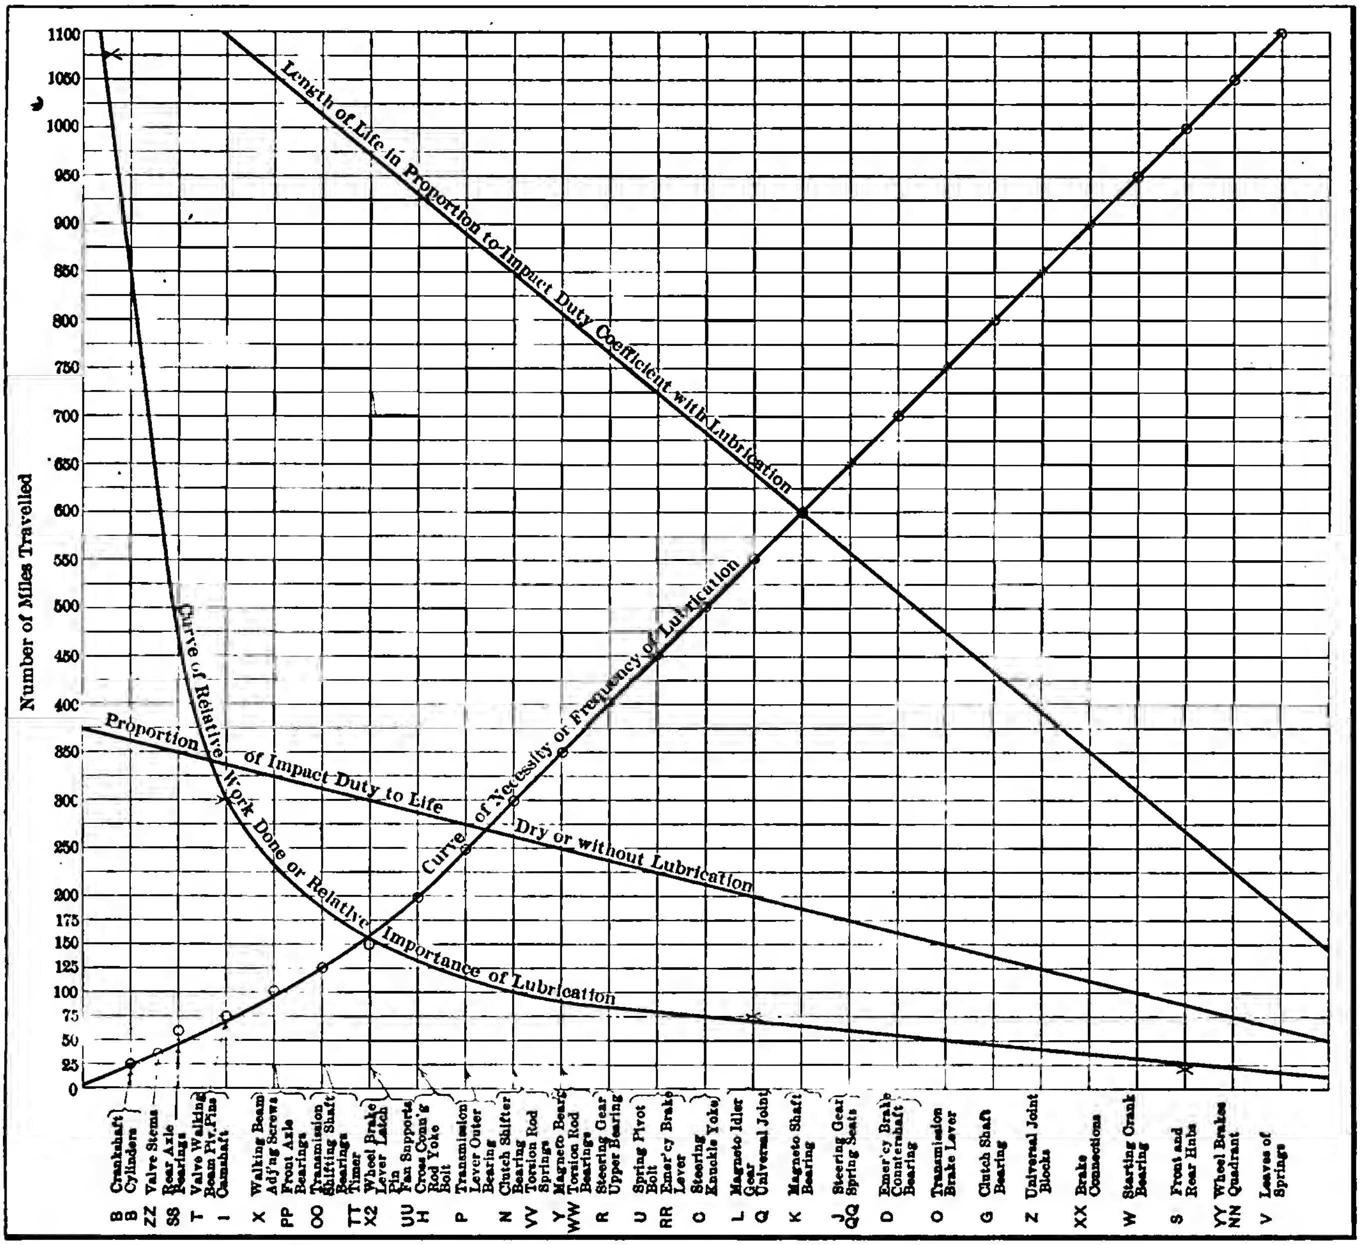
speed of rotation, while parts of partial rotation may easily be classed as of least importance. This, then, gives a relative relation of the turning parts, based upon number of turns. As the latter in a measure marks the necessity of or for lubrication, it is both logical and correct to label this curve, as has been done, relative work done or relative importance of lubrication. In inspecting this curve, it will be noted that it has a hyperbolic form due to the fact that the lineal or surface speed inducing friction and wear of any rotating part varies as the square of the number of rotations.

Of course, the nature of the curve, as just explained, is such that the highest point of the second curve is the lowest or starting point of the first. In other words, it is more important to always lubricate the crankshaft exactly on time, giving it an approximation to perfect lubrication, than it is to bother with the multitude of small and less important parts. This may be stated as follows: If you will neglect some parts, as to lubrication, by all means select those at the lower end of the second curve.

In this same chart will be noted a pair of additional curves. In plotting these, it was considered that the parts which make the greatest number of turns per unit time, and consequently, total, are those which have the greatest amount of duty charged against them. This duty has a direct and very close bearing upon impact so that the matter may be represented as an impact-duty coefficient, which would not be an ultra-difficult matter to determine in any one given case. This could be determined as a numerical quantity for purposes of pure reasoning, or simply as a series of results, for more general use.

Moreover, it is apparent that every piece in the machine has a certain length of life, which may be increased by superior lubrication. This length of life bears some close relation to the impact-duty coefficient, in that the greater the duty and impact, the more the care given to the design, material, workmanship, and assembling of the part, to say nothing of the lubrication care. All these combine to give the part of greatest importance a longer life, or at least a relatively longer life, when account is taken of the impact-duty coefficient. So, it is that this curve, length of life in proportion to impact-duty, will be found to slope continuously from the parts of greatest work done down to those of least work. In short, the curve is a straight line from the crankshaft to the rod ends.

To emphasize the beneficial effect of copious lubrication, another curve has been figured and plotted on the same co-



Curves Which Show Relation of Frequency of Lubrication to Relative Work Done and Impact-Duty-Life Coefficient

TABLE OF LUBRICATION ATTENTION NEEDED BY THE AVERAGE AUTOMOBILE CHASSIS

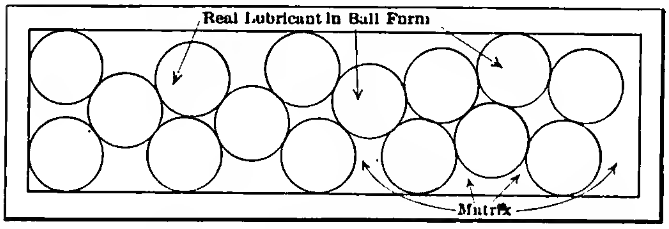
ordinates as the one just described, this being the same proportion of life to impact-duty, but without lubrication. Being based upon the assumption that a crankshaft running 600,000 revolutions without lubrication would be absolutely spoiled beyond repair, it probably represents an extreme case, since one-tenth of this is more nearly the average case. This curve, too, is a straight line so that the difference in the slope of the two curves or the area between them represents the loss which a man will incur by just simply being careless. The combination of the four curves closely placed is worthy of some study.

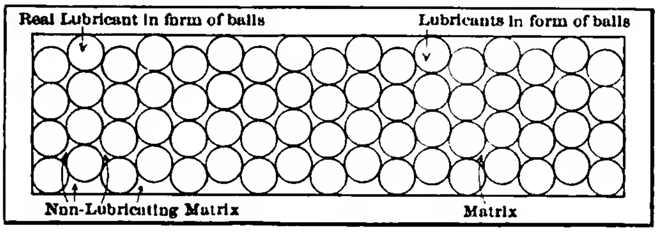
Lubrication as a subject is one that seemingly presents many angles, yet there are few things about it which will not yield to close application and study. Thus, speaking generally, there are two properties of all lubricants, in general, and oils or greases in particular, viscosity and body.



Imaginary Section Through Heavy Lubricant Showing Balls

The former, viscosity, is defined as that property by virtue of which lubricants form comparatively thick films between rubbing surfaces, thus permitting perfect lubrication. It has been defined by Davis as that property by which it clings to its own particles, or the degree of fluidity or resistance opposed to the separation of particles. This latter makes a difference between viscosity and adhesion, the latter being defined as the property of clinging to other particles than those belonging to itself.

The film spoken of as comparatively thick is in reality somewhat thin, having been measured by Reynolds as a minimum at .000375 in. in the case of a 4-in. diameter shaft, the bearing being larger by a radius of .00077, and the pressure being 100 pounds per square inch. Kingsbury in his experiments found the film to be of a thickness varying with speeds of from 80 to 190 revolutions per minute and loads of from 27 to 270 pounds per square inch from .00021 to .00023 inch.



Section Through Thinner Bodied Oil Illustrating Structure

These figures give some idea of the infinitesimal quantities, which are designated as comparatively thick. In the consideration of this film and the subject as a whole, a lubricant may be considered as a series of balls of one material, comparatively hard and resisting to some extent compression, these being encased in a body or matrix of non-lubricating or at least different lubricating qualities, the latter being very mobile. It is then conceivable that the shaft rolls upon the balls, the matrix simply serving to hold it together. Experimenters in this field find that the same lubricant often yields differing results in similar tests held under identical conditions. Is it not conceivable that this anomalous result is brought about by a variation in the quantity of matrix present, as well as the number and character of the balls, as to size, comparative hardness, comparative density of balls in the matrix and some other quantities?

This idea, as advanced and illustrated in several cuts on this page, is offered more for future than for present consideration.

One essential condition of film formation is that the rubbing surfaces should have a slight inclination to one another. This is furnished in the ordinary case by the difference in size of the shaft and the bearing. But when it is not furnished, lubrication is both imperfect and inefficient. Under these conditions, the effect of the lubricant in reducing friction between the two bodies depends upon that indefinable quantity called body or oiliness. This is not, like viscosity, understood, definite and measurable, but is considered as intensified viscosity in that part of the fluid which is within the region of attraction of the surface of the molecules of the metal, that is to say, it partakes of the nature of adhesion and attraction at the same time.

One bad feature of body from a testing standpoint is that it may be hidden by the effects of viscosity, which perhaps accounts for the lack of knowledge of it. In any one case under test, using a good fitting journal and bearing, the friction is determined definitely by three things: speed, pressure, and viscosity. Varying any one and holding the others stationary will give a varying result, but in each case a minimum value may be obtained.

In one test which the writer calls to mind, with a varying speed and pressure, this minimum was found at 180 degrees F. having a value slightly greater than .0005. In this test another point was brought out, the interrelation of viscosity and body.

TEST SHOWING RELATION OF VISCOSITY TO BODY

Increase of	Where Viscosity is Effective Coefficient of Friction	Where Body is Effective Coefficient of Friction
Pressure	Decreases	Increases
Speed	Increases	Decreases
Temperature	Decreases	Increases
Viscosity	Increases	Decreases
Body	....	Decreases

As the table above brings out, the variations in the two are diametrically opposite, one increasing when the other decreases.

(To be continued)

Interesting Test of a Centrifugal Pump

GENERALLY it is the understanding that the efficiency of centrifugal pumps will depend upon shaping of the vane to such an extent that great skill frequently falls short. There probably is something in this under certain conditions, as when very large pumps are required to handle vast quantities of water under high heads.

The following report made by H. Rees, for the E. R. Thomas Motor Company, seems to indicate that the main care is to have the vanes smooth and the inlet free from obstructions. The capacity of the pump, under automobile conditions, will then be up to the requirement.

The first pump tested was with rough cast impeller, the results being shown on the data sheet. The impeller rotating in such a direction that the convex side of the bucket or vane was forward. As the results were so close to those of the third pump tested the curve was not plotted.

A pump with the impeller inlet smoothed out and running in the reverse direction, i. e., with concave side of bucket forward, was then tested with the result as shown by data sheet, test No. 2, and small circles on curve sheet.

The third pump tested was identical with No. 1, excepting that the impeller inlet and deflector were smothered up. The curve is shown by the characters X.

The fourth pump had an impeller made up of sheet brass, the buckets extending tangentially from a 7-16 circle and being driven as shown on the curve sheet.

From the experiments it seems that it matters little which way the impeller is rotated, but considerable is gained by using smooth blades and an unobstructed inlet.

MODEL M CENTRIFUGAL PUMP

While the subject is up it will be opportune to settle one other point in relation to centrifugal pumps, using for the purpose tests from the same source. It is generally understood that the capacity of a centrifugal pump is as the square of the speed, and if this law holds, it follows that the amount of water delivered will be vastly more than the requirement at the higher speeds. The tests as follows will show just what is the relation of speed to delivery and that the square law does not prevail in small pumps as made for this purpose.

TEST OF A CENTRIFUGAL PUMP FOR A LARGE MOTOR

Head on suction side was maintained about 2 inches below top of radiator and head on delivery side about 6 inches above.

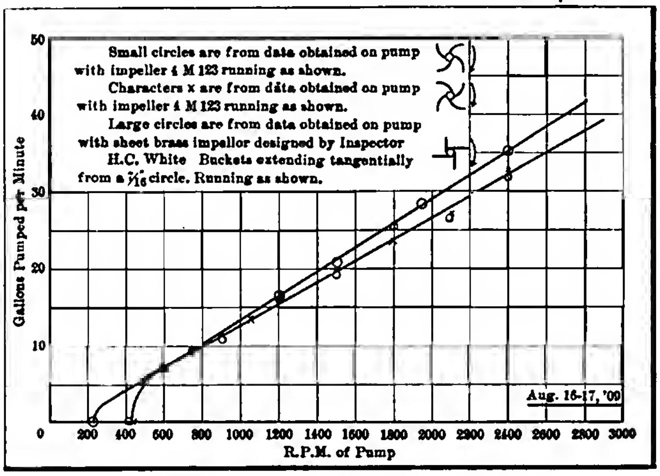
1800	19.5	...	29.5

It will be observed that the gear pump performs admirably, excepting that noise must be considered at higher speeds, and, as the test shows, there is a certain falling off in capacity as the speed increases. Since the cooling requirement does not increase with speed to any great extent, it is only the noise that has to be considered, unless with gear pumps the wear is greater.



Test Curves of Thomas Model M Centrifugal Pump

*An Improved Absorption Dynamometer**

By C. M. Garland, Urbana, Ill.

In testing prime movers, the engineer often laments the dearth of efficient power-absorbing apparatus. Especially is this true in the testing of small high-speed machines, such as automobile engines and steam turbines. In many cases the number of machines to be tested is large; in fact, in some instances each machine is given a brake horsepower test before leaving the factory; and in every case where a high degree of reliability is essential from the output, the percentage of machines undergoing test must be large. The attention of the writer was forcibly called to this need several years ago in the testing of a small steam turbine running at 2,300 revolutions per minute, and through this experience the type of apparatus described below was designed and has been used with satisfactory results.

In the design of such a piece of apparatus the following points were to be considered. These are enumerated in the order of their supposed importance.

a. It should be free from binding or "seizing."

b. It should be free from producing changes in the load, due to changes in the apparatus itself, such as change of temperature, wear or friction of parts, etc.

c. It should be capable of absorbing and accurately indicating a wide range of loads, from zero to the full capacity of the machine.

d. The regulation of the load should be positive and instantaneous.

e. The apparatus should require a minimum amount of attention and be capable of continuous service.

f. It should be self-contained, occupy a small amount of floor space, and be free from noise and the splashing of oil and water.

g. It should be capable of being quickly changed from one prime mover to another.

h. It should require a small amount of cooling water.

In considering the above items, it will be noted that items *a* and *b* practically eliminate mechanical-friction apparatus from the field, while items *b*, *c* and *d* practically eliminate machines depending upon the friction or resistance of liquids for their operation. With these two classes of apparatus removed, there only remained the principle of magnetic induction for the construction of an efficient absorption dynamometer.

THEORY OF ACTION

From this principle we know that a conductor revolving in a field of variable magnetic intensity has an electric current induced in it. The reaction of this current upon the field that produces it causes a torque between the conductor and the field. There are two ways of dealing with the current induced in the conductor. In the one, the current may be collected by a commutator or slip rings and carried off from the machine; in the other, the current, or rather currents, generated in the conductor may be allowed to remain, and, circulating in the paths of least resistance, they will ultimately short-circuit among themselves and produce heat.

In the first case, we have simply a dynamo mounted in a cradle. This serves as a very efficient and satisfactory type of dynamometer. There are, however, objections to its use. The currents generated must be taken care of either by water rheostats or lamp banks or utilized in the performance of work. Water rheostats and lamp banks require considerable attention and occupy space. Owing to the irregularities in the testing, the utilization of the current for the performance of work is in most cases impracticable. The initial cost of a testing unit of this type is necessarily large.

If the currents in the conductor are permitted to short-circuit themselves, the conductor is heated; the amount of heat produced

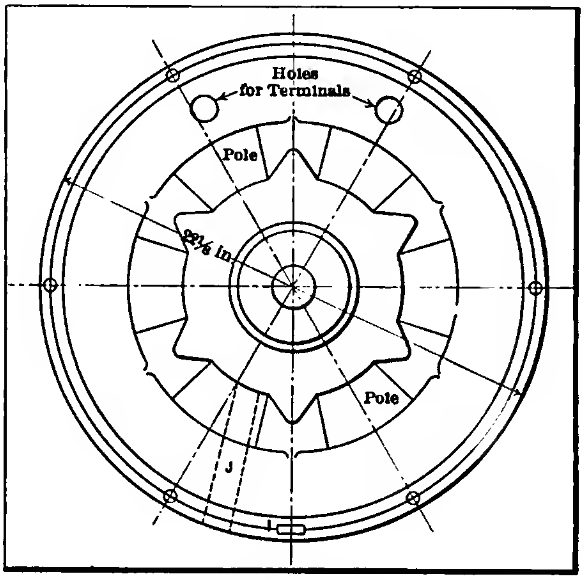


Fig. 2—Left half of field casting, Garland Dynamometer

is equivalent to the work absorbed by the dynamometer; and the heat thus generated may then be carried off by cooling water. This is the principle utilized in the design illustrated, a description of which follows.

DESCRIPTION OF DYNAMOMETER

In brief, the dynamometer consists of a metallic disc revolving between a set of pole pieces so constructed as to produce a magnetic field of variable intensity. Fig. 1 shows the front view of a machine designed to absorb 45 horsepower at from 1,200 to 1,500 revolution per minute. Fig. 2 is an end elevation and part section showing the construction of the dynamometer. It will be seen from this figure that it consists of a copper disc *A*, mounted on a bronze hub and revolving in front of pole pieces *B B'*. The magnetic circuit is made up of the casting *C*, the air gap and the cover plate *C'*. The castings *C* and *C'* are bolted together and carry the exciting coil *D* and the bearings *E* and *E'*. The magnetic yoke, made up of casings *C* and *C'* carrying the field coil and disc, is supported in ball bearings, and is prevented from rotating with the disc by the spring balance shown in Fig. 1. This latter measures the pull or torque between the rotating disc and the stationary yoke.

The magnetizing coil is encased in copper, the terminals being carried out through holes in the casting *C*, which are carefully sealed after the coil is in place.

The heat generated by the short-circuiting of the eddy cur-

* Paper read before the Boston meeting, American Society of Mechanical Engineers, March 11.

rents generated in the copper disc, is carried off by the cooling water which enters through the base connection at *F* (Fig. 2) and passes up through the bearings into the field casting. It then passes out through openings which are not shown in the illustration. This water not only carries off the heat generated, but serves as a lubricant for the bearings. That which passes through accumulates in the central chamber *E*, and is discharged at the base of the machine through the drains *G G'*.

Fig. 2 is a detail drawing of the left half of the field casting *C*, shown in section in Fig. 1. It will be seen that there are six poles in the machine. The circulating water enters at *I* and leaves through the port at *J*. Similar ports are provided in the cover plate *C*, Fig. 2.

OPERATION OF TEST

In operating, the engine under test is directly connected to the dynamometer shaft by means of some form of flexible coupling, the cooling water is turned on and the engine is started. After normal speed is reached the load may be thrown on by energizing the field coil. The amount of current and consequently the torque or pull on the spring balance is regulated by a rheostat connected in series with the coil. After running a few minutes the quantity of cooling water is adjusted so that the temperature of the machine does not exceed 150 deg. Fahr. In larger machines the coil may be wound with asbestos-covered wire and the temperature permitted to reach 212 deg., so that the cooling water is evaporated within the dynamometer. This reduces the quantity of cooling water required about 75 or 80 per cent.

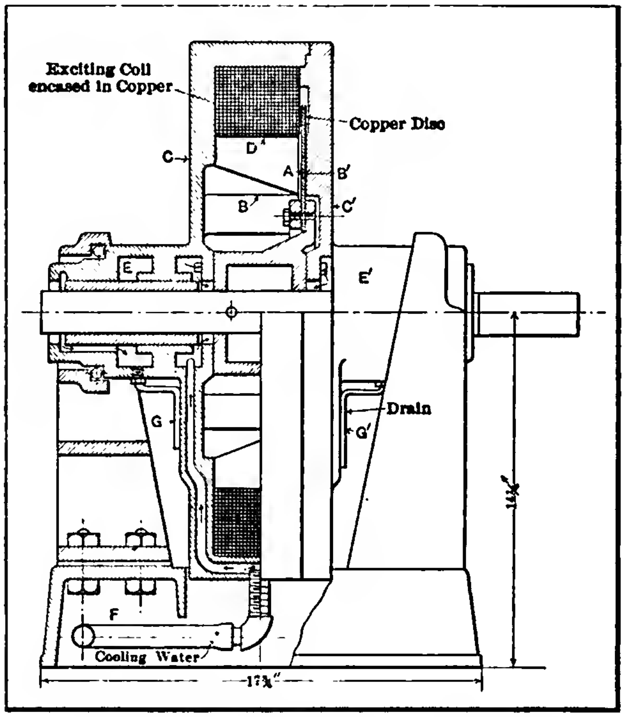

Fig. 1—Section through New Garland Dynamometer from end

The normal working temperature having been reached, the load on the machine remains absolutely constant, provided the line voltage is constant, for the mechanical friction, which is the bearing friction of the revolving disc, is small and practically constant, and changes in temperature due to changes in the supply of cooling water also affect the load on the dynamometer very little. The regulation hy the rheostat is instantaneous and positive. When the dynamometer is driven by a smooth-running engine, the torque as indicated by the spring balance will not show a variation of 1-8 pound, while the balance is sensitive to less than 1-16 pound. This indicates an accuracy that is not necessary even in the most refined testing work.

RELATION BETWEEN SPEED AND TORQUE

In the case of the present machine the torque is almost proportional to the speed and is maximum at about 600 revolutions per minute. From this point the torque props off about 15 per cent. at 1,200 revolutions per minute, and remains almost constant from 1,200 to 1,500 revolutions per minute.

The torque depends upon the speed, number of poles, thickness of air gap, thickness of the copper disc, shape of the copper disc, and shape and spacing of the pole pieces. By varying the number of pole pieces, and the thickness of the copper disc, the point of maximum torque on the speed-torque curve may be shifted anywhere from 25 revolutions per minute to 2,500 revolutions per minute.

CONCLUSION AND RESULTS

This type of dynamometer is well adapted either for the testing of high-speed motors with a wide variation in speed, such as the automobile engine, or for the testing of slow-speed apparatus having a small variation in the speed. It can be built in practically any size from 10 horsepower up. The principal disadvantage is the high initial cost, although this is not an item where serious and continuous testing work is going on, as in factories or in the laboratories of technical schools, for the labor saved and the increase in capacity resulting through the use of the machine will in a short time more than pay for the initial outlay.

The efficiency, which may be expressed as the ratio of the energy absorbed by the dynamometer, minus the energy supplied to the exciting coil, divided by the energy absorbed by the dynamometer, may be made anything up to 99.9 per cent. and depends upon the weight of copper placed in the coil. Ordinarily the efficiency is made about 96 per cent., or 4 per cent of the power absorbed by the dynamometer is required in the form of electrical power for excitation.

Electric Vehicle Operation Cheaper Than Horses

UNDER the above heading, the following masterly summary of the electrical vehicle situation was printed in a recent issue of the *Electrical World:*

"The investigation boils down to this: that in the case of the Commonwealth Edison Company, where a large number of electric power wagons and horse rigs has been employed side by side, the actual cost of operating the electric vehicles is shown to be sensibly less than that of operating the horse-drawn vehicle. The comparison has been made very carefully and thoroughly and the result is a triumph for the electric commercial wagon.

"Furthermore, the cost of operating electric vehicles is decreasing rather than increasing, whereas the reverse is true in the case of the horse-drawn rigs. The decrease in the case of the electric type is due to improved construction, greater care in operation and decreasing cost of electricity. The increase in the cost of operating the horse wagons is largely to be ascribed to the constantly rising price of feed. The electric vehicle has the advantage also in that it presents a better appearance and makes for a cleaner, more sanitary city. In the matter of maintenance of pavements, also, the electric vehicle possesses a decided superiority. Weight for weight, the electric wagon will cause less deterioration of the pavement than the horse wagon, to say nothing of a substantial reduction in the cost of street cleaning where the electrics are employed. Again, the greater ease of control and compactness of the electric vehicles tend to relieve the congestion on the streets of large cities.

De Lesseps at the Wheel of his Own Monoplane, "Le Frégate"

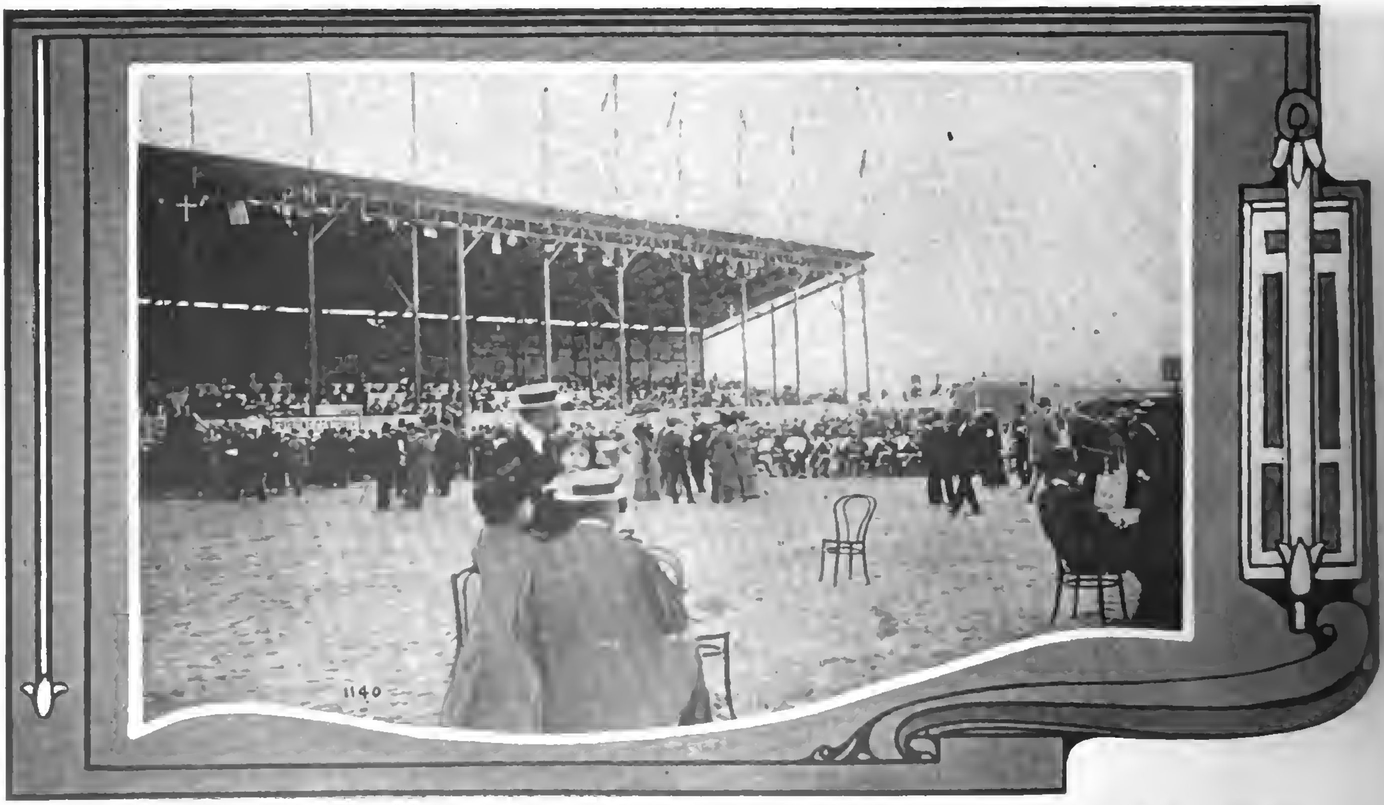
ACCIDENTS, both to men and machines, marked the aeronautical meet at Heliopolis, Egypt, in the shade of the Pyramids, from February sixth to thirteenth, eight days of flying. Nearly all the accidents were due to the winds, which were unusually severe at times. Such spells of windy weather were followed closely by unusual calms, so that, taken all in all, it averaged up to good flying weather. The accidents to men totaled four, one being somewhat serious, while no less than six machines were seriously damaged, three of them being reduced to scrap.

Some of the accidents took place before the week of flying actually opened, so that the aviators were not only deprived of the use of their machines, and in some cases, the personal ability to manage a 'plane, but were obliged to sit by later and see others win valuable prizes. The latter were indeed liberal, being distributed over the single days, for each of which there was a prize of $200, in speed, height, and distance, but also for the whole meeting, including as grand prizes the following: Prix de Baron Empain, for the greatest distance for a single uninterrupted flight, $10,000; second prize, $2,000; third prize, $1,000; fourth $500; fifth, $500 and sixth $200. Then there was the Prix d'Heliopolis for maximum height; first $10,000; second, $2,000, and third, $1,000. For the flight from Heliopolis to the Pyramids and return the prize consisted of a cup valued at $400, and $2,000 in cash added. Finally, for the greatest total distance for the whole week, made in official flights, the Grand Prix d'Egypte, amounting to $5,000 for first, $2,000 for second, and $1,000 to the winner of third. All in all, the stakes were rich, amounting to more than $40,000.

Of this Rougier gained the greater portion amounting to nearly $19,000, which he secured by winning the Prix d'Heliopolis for height, the Grand Prix d'Egypte for greatest total distance, as well as a number of the smaller daily prizes.

Next to Rougier, the prize winners were Métrot, who won the Prix de Baron Empain; Le Blon, who captured the prize for speed over a measured 10 kilometres (6.21 miles), and Balsan, the fastest over a measured 5 kilometres. The latter was numbered among the unfortunates, in that on the third day of the meeting, when the wind was unusually severe, he was the only one to attempt a flight. This, as it turned out, was a foolhardy thing to do, for on his first turn an adverse wind bore him to the ground and wrecked the machine. Fortunately he was not injured personally, and, being able to secure another machine. continued his spectacular flights.

On the first of February, five days before the meeting, Mortimer Singer suffered a deplorable accident, which, coupled with a similar accident to Latham, served to call attention to a



General View of Crowd and Grand Stand at Heliopolis Aero Meeting. The Khedive of Egypt Was an Interested Spectator

hitherto overlooked item, the effect of eddy currents upon an aviator. This accident to Singer, and the similar, though fortunately less disastrous, mishap which overtook Latham flying at the same place on his Antoinette monoplane, have once more drawn the attention of aviators to the dangers attending flight in what appears to be a dead calm of the atmosphere. It will be remembered that the first serious accident which happened to an aviator using a motor on his flying machine was due to the same cause as those which have just occurred at Heliopolis, or at least it took place under similar circumstances. It was in perfectly still air that Henry Farman, flying at Issy-les-Moulineaux on the Voisin aeroplane with which he had, about a month previously, gained the Deutsch-Archdeacon prize by traveling in the air a kilometre out and home to his starting point, was capsized by a rising current which caught only one of the wings of his machine. At least that was the impression of the pilot, who was stunned by the fall and cut about the face by the wire stays of the aeroplane. Since then numerous aviators have experienced the inconvenience of the eddies which rise from the ground in an apparently still atmosphere. Those eddies or little whirlwinds are most treacherous, and experienced aerial pilots quite agree with Latham's opinion that it is less dangerous to confront a fairly strong breeze than to fly in a dead calm. However, when in a still atmosphere the aviator has risen to a certain altitude the danger from the eddies is less, if it is not entirely absent, firstly because those eddies widen out and lose much of their strength before they reach a great height, and secondly, because the pilot, if caught by one of them, has time to right his machine, which is not the case when flying at a few yards from the ground. Also, the greater the speed of a flying apparatus the smaller the danger of its being upset by an eddy.

Goux, Voiturette Driver, at Wheel of Peugeot-Rossel Monoplane

The proceedings on Wednesday, the ninth inst., were extremely interesting. More of the competitors actually figured in the contests than on any of the preceding days, and the spectators were delighted by witnessing Duray, the famous motorist, break the world's record for five kilometres. His time for that distance was 4 min. 12 4-5 sec., and his machine a Farman biplane. The daily speed prize of $200, for a distance of ten kilometres, was won by Balsan (Blériot) in 9 min. 50 2-5 sec. Another feature of the day's proceedings was the appearance of Latham, who won the $200 prize for altitude, he attaining the height of 170 feet. The daily prize for distance was secured by Métrot on a Voisin biplane, who covered 85½ kilometers (57.2 miles). The day did not pass without an accident, for Hauvette-Michelin was wheeling his Antoinette monoplane into its shed when the machine toppled over and smashed a wing. Hayden Sands, an American, driving an Antoinette monoplane, succeeded

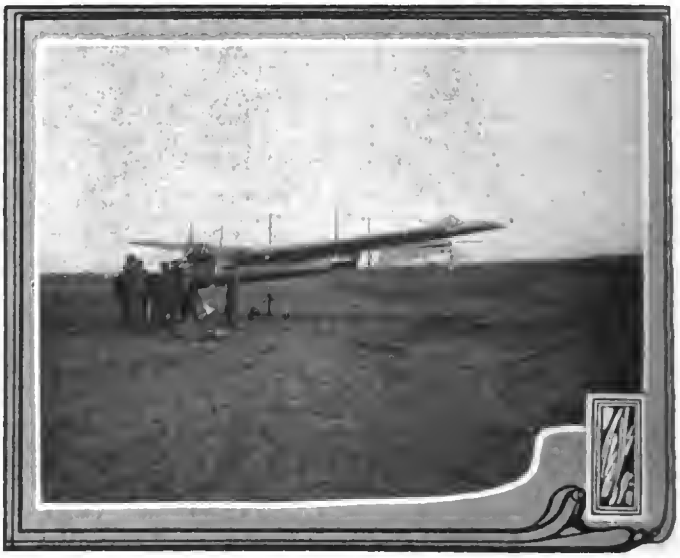
in making a notable performance by flying five kilometres in 4 min. 22 sec. He was, however, not competing officially. Owing to the unfavorable weather there were no flights of importance on the tenth inst. In the morning Mme. Delaroche secured a pilot's license from the French Aero Club by flying four times round the course, a distance of over twelve miles. She is the first woman to win the distinction. On Friday, the eleventh



Latham and Antoinette Number One on Ground

Details of New Darracq

PARIS, March 7—The construction of aviation motors has already attained such proportions that few automobile manufacturers can afford to ignore it. Thus it is not surprising to find that a firm of the standing of Darracq has also produced a light-weight for work in the air. A start was made by a request from Santos-Dumont for a two-cylinder horizontal capable of developing 30 horsepower for more than a few minutes, and not exceeding 4½ pounds per horsepower. Such a motor had been produced, but had never been capable of running at full power for any length of time. The preference for a two-cylinder horizontal was by reason of its shape, allowing it to be placed in the angle of the wings of a monoplane with a lower center of gravity than with vertical cylinders.

There is nothing very extraordinary in the general design; indeed, it is what Designer Ribeyrolles calls a retrograde motor, for the horizontal type was abandoned in France almost before it was given a fair trial. But there is considerable ingenuity in the working out of details and in the abolishing of parts hitherto considered necessary, with a consequent reduction in weight. The two cylinders, having a bore of 5 1-10 inches and a stroke of 4 7-10 inches, are machined out of the solid bar of steel until their weight is but 8 4-5 pounds complete. The head is separate, carying the seatings for the inlet and exhaust valves, is screwed onto the cylinder, and then welded in position. A copper water-jacket is fitted, and it is in this condition that the weight of 8 4-5 pounds is obtained. Steel pistons are employed, with light rods connecting up to a two-throw crankshaft.

The distinctive feature of the motor is to be found in the valve operating mechanism. There are but two pinions, two shafts, and two cams in the entire motor. On the main shaft is mounted a driving pinion with a slight bevel, meshing with the two-to-one pinion, the shaft of which carries the two cams, drives the magneto and the water circulating pump. The plunger type of lubricating oil pump is operated by an eccentric machined with the bevel gear on the main shaft. The reason for employing bevels in the timing gear is to avoid the use of an intermediary gear between the driving and the driven shaft, the maginst., Rougier carried off the distance and altitude prizes, while Le Blon on a Blériot monoplane secured the speed prize by flying ten kilometres in 8 min. 74-5 sec. At one time there were three aviators—Rougier, Le Blon and Grade—in the air. There were no flights on Saturday owing to the violent wind, but on Sunday Balsan established a new record for five kilometres by flying that distance on his Blériot in 4 min. 1 sec.

Light Aviation Engine

neto necessarily being set too high to take the drive in the ordinary way. The push rods are not parallel, but gradually come together until they almost touch, this being necessary because of the placing of the two cams very close together on a short shaft. One cam operates two inlets and the other two exhaust valves.

Rocker arms are drilled to reduce weight, and the push rods are steel tubes with lock-nut adjustment to allow for wear. The spindle on which the two rocker arms are mounted is a steel tube passing directly into the cylinder and provided with a priming cock, thus fulfilling two functions without any increase of weight. The spark plug is mounted in the cylinder head midway between the two valves.

The carbureter is original by reason of the manner in which it is mounted. It is constructed of aluminum, and is of the float-feed type, the mixing chamber being cast with a sleeve fitting round the straight length of intake pipe uniting the two intake ports. A single vertical jet passes into the mixing chamber, and is heated at its base by a bypass from the exhaust. An additional air valve is fitted in the head of the mixing chamber, but in view of the fact that auxiliary exhaust ports are provided, is only given a very slight opening, a large quantity of air of course entering through the exhaust ports. A series of ten exhaust holes are bored in the cylinder at the end of the stroke, and occupy almost one-half the circumference. They are surrounded by an aluminum collector, the mouth of which is turned in the same direction as the main exhaust ports, thus allowing a manifold and a muffler to be fitted without difficulty, if desired.

On the bench, the motor has furnished 34 to 35 horsepower without any falling off in power at the end of a long run. Fitted complete with lubricating oil for three hours, water, magneto, carbureter, but without gasoline, its weight is 121 pounds, thus securing the very unusual result of less than 4 pounds per horsepower. A similar type of motor, with four horizontal cylinders, has also been produced and is being used for the first time on a Voisin biplane driven by Rigal, the automobile race driver.

RECENT CLUB ACTIVITIES

QUAKERS TO HAVE MANY ROAD EVENTS

Philadelphia automobilists are arranging for coming competitive events, including endurance and roadability runs, hill climbs, etc.—these to take place not alone in the Quaker City, but within 150 miles. This year the season will be opened with a three day roadability run of the Quaker City Motor Club to Atlantic City, N. J., from April 30 to May 2. It is expected that fully 100 cars will compete for the prizes in this event. Through a plan evolved by the secretary, Harry Harbach, there will be a prize given for each car that goes the route. A two day show of the competing cars at the Million Dollar Pier at Atlantic City, will form part of the program.

A number of local enthusiasts will enter cars for the big Harrisburg Motor Club run occurring in the first week in May. This run will in all probability end in Pittsburgh, and owing to the difficult route and strict conditions for which the Harrisburg Club contests are notable, the contest will be well worth while.

There will be the usual outpouring of Philadelphia car owners at Wilkesbarre next June at the contest known as the Wilkesbarre hill climb. An additional attraction will be that feature of the program embodying two events open only to the members of the Quaker City Motor Club. On Fourth of July and Labor Day, meets are arranged as usual.

President L. D. Berger, of the Quaker City Motor Club, has announced the personnel of that organization's Contest Committee, as follows: R. C. Ross, chairman; Fred C. Dunlap, A. T. James, G. Hilton Gantert, Paul B. Huyette, Evans Church, George M. Graham and A. E. Maltby.

NEW ADMINISTRATION FOR K. C. AUTO CLUB

Kansas City, Mar. 14—The Automobile Club of Kansas City, under a new administration, headed by Frank P. Ewins, will carry on the progressive policies of former administrations, with a few original plans of its own. The new president, Mr. Ewins, who succeeded W. W. Cowen, is prominent in motor circles. Permanent headquarters were opened March 1 in the Midland Building, where Secretary Stevens will have his office and where members will at all times have a place of meeting and bureau of information. Following is the committees for the present year: Finance—D. E. Gudgell, chairman; C. V. Purcell and Dr. E. M. Hetherington. Membership—H. T. Fowler, chairman; W. G. Whitcomb and F. E. Lott. House—F. P. Ewins, chairman; H. T. Fowler, Fred C. Merry, A. W. Peet and L. H. Fisher. Auditing—Edward F. Webster, chairman, Dr. G. L. Henderson and Charles H. Moore. Racing—Dr. F. George Curts, chairman; H. E. Rooklidge, R. E. Wiles, Carl J. Simons and R. M. Rigby. Good Roads—W. W. Cowan, chairman, F. C. Merrill, F. E. Lott, R. E. Bernheimer and J. M. Davison. Runs and Tours—W. G. Coumbe, chairman; H. NEW OFFICERS FOR NUTMEG A. A.

New Haven, Conn., Mar. 14—At a meeting of the Connecticut Automobile Association held Friday afternoon at New Haven, Conn., the following officers were elected for the ensuing year: President, F. T. Staples, Automobile Club of Bridgeport; vice-president, John N. Brooks, Litchfield County Automobile Club; secretary, Philip E. Curtis, of Automobile Club of Hartford, and treasurer, C. H. Gillette, of the Automobile Club of Hartford. The home office of the association is by vote to be established permanently in Hartford owing to the fact that that city is the capital of the State. F. T. Staples, the newly elected president, was vice-president during the past year and now holds the office made vacant by the death of William F. Fuller some time ago. John N. Brooks, of Torrington, the newly elected vice-president, has served as secretary for the past year. C. H. Gillette, the treasurer, was a former secretary of the American Automobile Association. The membership of the State body is now about 900. The next meeting of the directors is to be held March 18.

SHOW BREVITIES

SIOUX CITY, IA., HAS ITS FIRST SHOW

Sioux City, Ia., Mar. 14—An unprecedented crowd of more than three thousand people packed the Auditorium on the first night of the automobile show, which opened March 1, and tried in vain to inspect all the exhibits. Every exhibit was in place at the opening hour, and every foot of floor space was occupied. Grecian pillars mark off the spaces, each being topped with a potted plant and signs with the names of the cars exhibited. Over each space hangs a sign of uniform size and lettering announcing the name of the firm. The scheme of decoration has been carried out thoroughly and artistically.

The cars exhibited are the Inter-State, Reo, I. H. C., Ford, Rambler, Buick, Velie, White, Knox, Cadillac, Stevens-Duryea, Baker Electric, Cartercar, Lambert, Apperson, E-M-F, Mitchell, Chalmers, Hudson, Overland, Marion, Jackson, Fuller, Firestone-Columbus, Maxwell and Thomas. Motorcycles and accessories are also prominent in considerable numbers.

Dr. F. A. Seemann, president of the Sioux City Automobile Club, which organized the show, has expressed himself enthusiastically over its success, and declares that annual shows are now assured in Sioux City. All the dealers who are taking part radiate smiles as they see their dreams materialized. In fact, the reality exceeds even the dreams.

TOLEDO WILL HAVE AN OPENING WEEK BUT NO SHOW

Toledo, Mar. 14—Toledo will have no automobile sbow this year but instead will have an "opening week." This has been definitely settled upon by the Toledo Automobile Dealers' Association, and the week beginning March 28 has been determined upon as the least conflicting with other similar displays in the country. Although having formerly decided to have a sbow beginning the same date and in the Coliseum where the show was held last year, the plans were altered on account of lack of room, that hall being much too small to afford space asked for within a few hours after the date of the show had been arranged. Under the new arrangement, each dealer will be limited as to the space he may occupy, only by his own quarters or by those which he may be able to lease. Practically all the vacant store rooms available have already been leased and arrangements thus far agreed upon call for displays on a much more magnificent scale than ever undertaken in this city heretofore, although the various displays will not be under one roof. Several new factories for the manufacture of automobile accessories are being or are about to be built in this city, all of which owe their removal to this city to the activity of the Willys-Overland company, which has more than doubled its number of employees during the past two months, the total number of which is now in excess of 3,000.

WINDY CITY WHEEL TAX UNPOPULAR

Chicago, Mar. 14—The wheel tax of two years ago, which has proved so unpopular, and has aroused so much protest on the ground that it is harmful to the sport, because it is unequal, is now up again for discussion. As matters stand now, motor cars are taxed on seating capacity, which works a hardship on the little fellow in that the owner of a $500 car has to pay as much wheel tax as does the man who drives a 70-horsepower, seven-passenger car, providing the little fellow has a rumble seat and is capable of carrying three passengers. But this is not all. The drivers of horse-drawn vehicles are favored in the taxes in that their rates are not half as much as the motorists'. A single-horse rig pays $5 per year, a two-horse rig $10 and a three-horse $15, while the smallest sum the motorists can get out for is $12 on a two-passenger machine. Added to the inequality in the rates the motorists are complaining of another clause in the law which allows each city, village or township throughout the State to impose a wheel tax if it so desires. If any number of these

ROAD BUILDING NEWS

A. C. OF PHILADELPHIA ACTIVE IN GOOD ROAD WORK

Philadelphia, Mar. 14—Few organizations in this country whose efforts are not wholly directed to the making and maintenance of good roads, are doing more along this line than is the Automobile Club of Philadelphia. And this despite its activities in sign boarding routes, map and road-book making and in forwarding legislation favorable to automobilists in general. Its apparent disinterestedness and "for-the-good-of-all" policy, however, is well worth while, for each succeeding month sees several scores of additional members on the rolls; so that having attained its ambition of reaching the thousand mark, the membership committee is now aiming to reach the 1,500 point, which, at the present rate of progress, should be attained by the middle of 1911.

Besides its work on the Delaware Water Gap route, whereby a 33-cent toll extortion was forever sidestepped and a good bit of road laid down where a quagmire formerly existed, the Club's Good Roads Committee is spending money here and there along the Philadelphia-Baltimore route, eliminating the bad spots until it is hoped that in a few months there will be a direct route between the two cities, via Perryville, that will do away with the long detour via Lancaster.

But the Club's most recent work and the most beneficial to a great majority of Philadelphia's automobilists, is its labor toward putting the old Haverford-Conestoga road in good shape for motor travel. This road parallels the old Lancaster pike, which, although always in tip-top condition, is anathema to all motorists by reason of its numerous toll-gates. Upon the completion of this work—and the club is now busily engaged in raising the necessary $2,000 to finish it—automobilists will be enabled to keep their coats buttoned, and be forever released of the necessity of constantly digging into their jeans.

Not content with the carrying out of these important projects, the Good Roads Committee has been agitating the dragging and rebuilding (where necessary) of the bad 10-mile stretch of the Lancaster pike, which lies beyond the toll zone, near Gap and Bird-in-Hand.

W. O. Griffith, chairman of the Club's Signboard and Touring Committee, attended the organization of the Inter-County Good Roads Association at Coatesville last Friday and not only announced that Philadelphia had $500 ready to hand over when wanted, but that the Automobile Club of Delaware County pledged itself to contribute $200 toward the work. This was followed by the announcement of the Lancaster Automobile Club, through Dr. Donald McCaskey, that it could be drawn on to the extent of $2,000 to carry out the project.

LAW AND THE AUTOMOBILE

did so it would mean the death blow of motoring in the State of Illinois, for there could be no touring unless at great expense, for motorists would have to pay out a small fortune in wheel taxes just to cross the State. The supreme court of Illinois has upheld the validity of the wheel tax, and while the motorists feel that they are right in their contention that such a law is unconstitutional, yet they believe they can obtain some relief by first having the city council of Chicago revise the wheel tax and cut the figures in two and later go down before the State Legislature and pass an amendment whereby it will be impossible to impose more than one wheel tax on any one person. The Chicago Motor Club has taken up the cudgel and is preparing to appear before the license committee of the city council, which is to meet Friday afternoon, at which time the club will ask that the rates be revised, taxing on horsepower instead of seating capacity, and making the fees $6, $8 and $10 instead of $12 and $20, as they now are. They also want to have something to say in the future regarding the expenditure of this money, desiring that the city provide suitable exits in order that tourists may get out of town without having to travel miles over poor pavements. Every day during one recent week mass meetings were held at the Chicago Motor Club headquarters in the New Southern Hotel which have produced many recruits, so that in all probability an army of determined owners will swoop down on the aldermen.

CAMPAIGN FOR ADOPTION OF FEDERAL REGISTRATION

That the automobilists of the country keenly realize the necessity for the Federal registration of automobiles has been well illustrated as a result of the recent legislative convention held in Washington under the auspices of the American Automobile Association. The strong plea made at the hearing in Washington before the Committee on Interstate and Foreign Commerce, which is now considering the Federal Automobile Bill, has been productive of most beneficial results in all of the large State associations and the more important clubs affiliated with the American Automobile Association.

A strenuous campaign has been inaugurated by many of the leading clubs, and particularly throughout the State of Illinois, toward impressing upon the members of the committee the great value of this National Registration Bill to the automobile industry at large, which has now come to be one of the greatest commercial interests in the country. While it is recognized that the benefits to tourists traveling from one State to another will be immeasurably improved by the adoption of this bill in Congress, the fact is also admitted that it will directly and indirectly aid every department of motoring, whether for business or pleasure.

The deep interest shown by the members of the Committee on Interstate and Foreign Commerce, and their admission that the broad principles of the bill were just and reasonable, have been a great encouragement to the active motorists who have been working for equable laws on this basis during the last three years. Some minor changes to the bill have been deemed advisable and these are now being made, and the bill as amended will shortly be ready for definite action by the committee.

Cincinnati's Superb Show

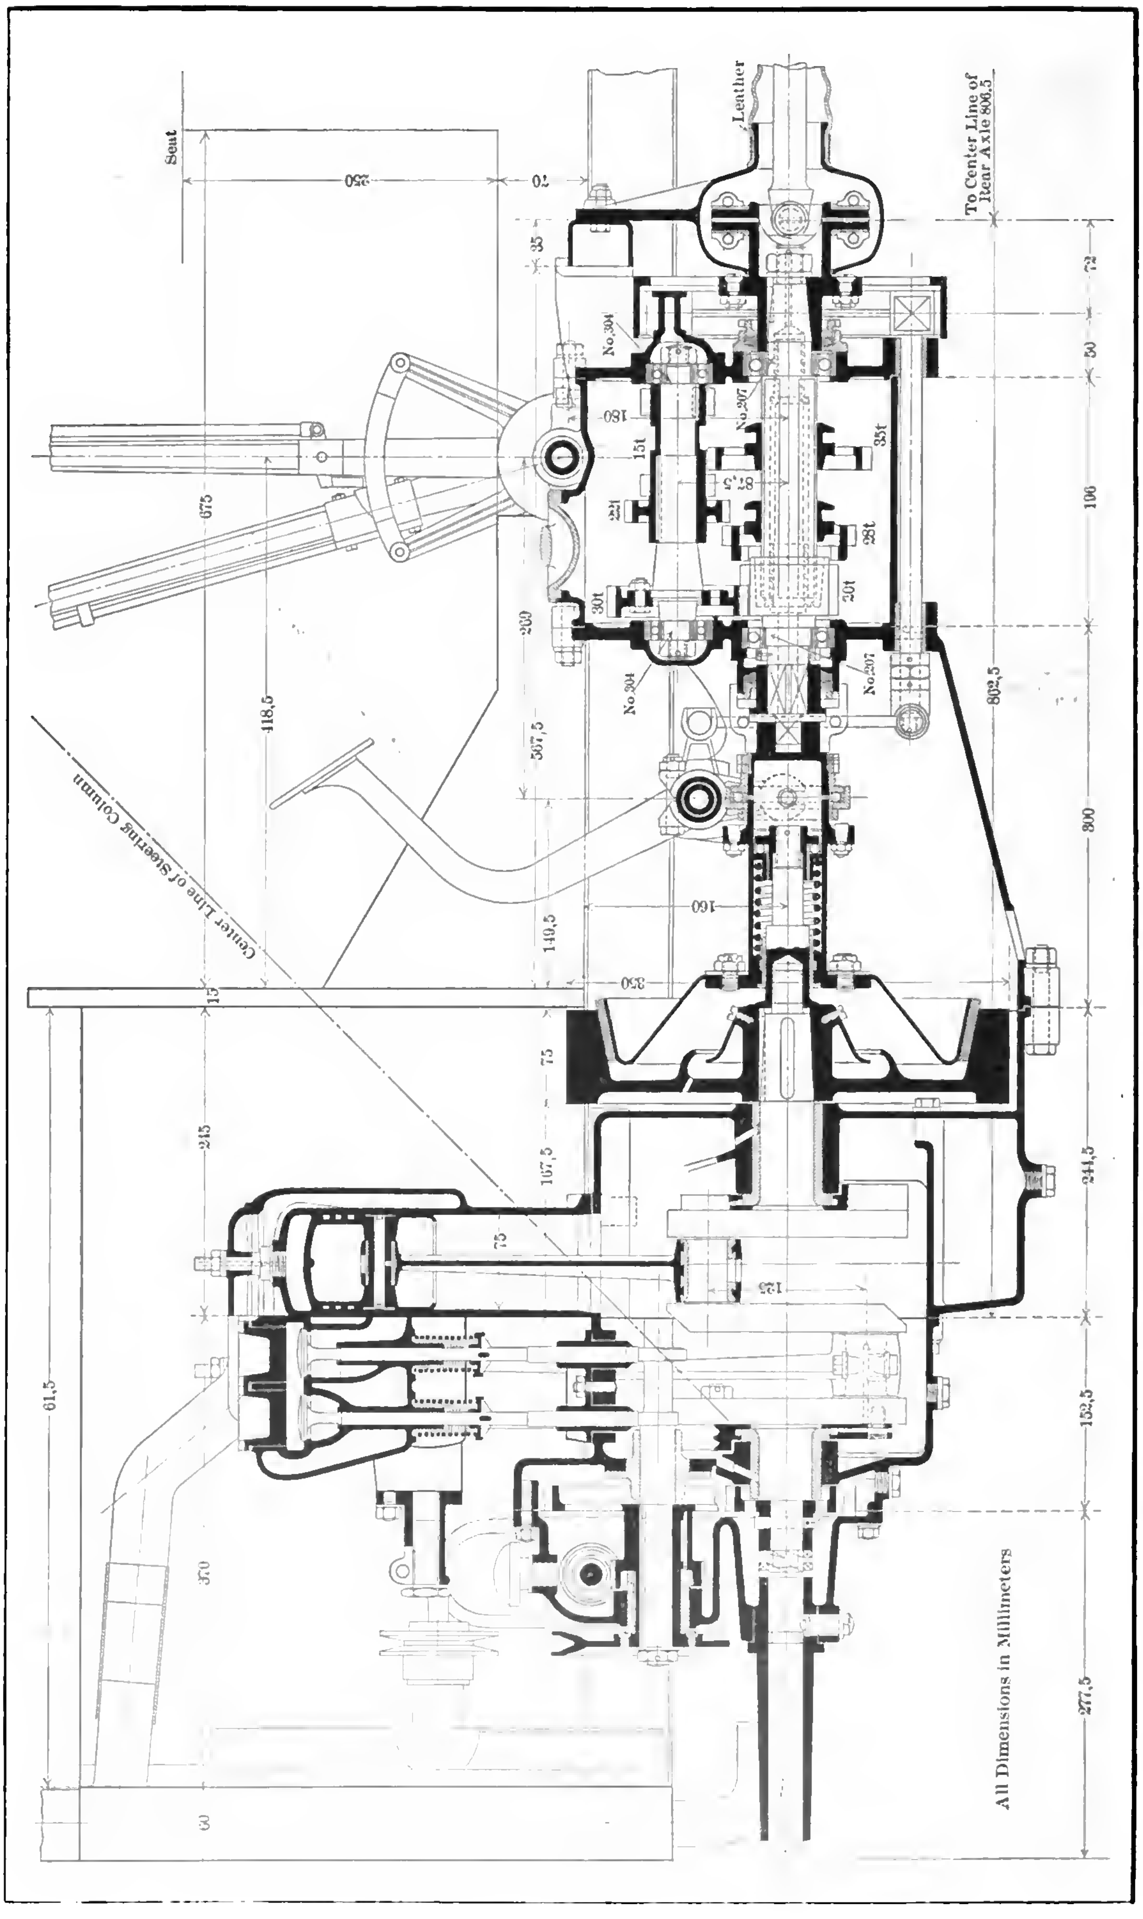
Fountain at Entrance to Music Hall, Where Cincinnati's Second Show Was Held, Amid a Profusion of Palms

CINCINNATI held its second annual show in Music Hall, the city's largest auditorium, and that the move was a wise one is evidenced by the 31,363 square feet of space sold to exhibitors. The hall was attractively decorated with pergolas of Doric columns, covered with Southern smilax, and potted palms and other semi-tropical plants were set about in profusion. Some fifty concerns exhibited 170 automobiles, besides many accessories. The aeroplane, without which no show seems to be complete this year, occupied a prominent position, and was accompanied by a small spherical balloon. The show was under the auspices of the Automobile Club of Cincinnati, with Rutherford H. Cox acting as general manager. Many sales were reported, and the dealers and manufacturers who participated seem well satisfied with the results. There can now be no doubt that the show will be an annual fixture. The list of exhibitors follows:

Atlas Motor Car Co., Interstate; Auto Jack Distributing Co., automobile jacks; Avondale Auto Supply Co., accessories; Louis E. Bedinger, Ferro marine engine, Mullen steel boats, K-W magnetos; Chas. Behler Sons Co., Brush, Maxwell, Columbia, Bailey electric; Buckeye Motor Car Co., Parry; Bumiller-Remelin Co., accessories; Cincinnati Automobile Co., Peerless, Pope-Hartford; Cincinnati E-M-F Co., E-M-F Thirty, Flanders Twenty; Citizens Motor Car Co., Packard; Coughlin & Davis, accessories; Covington Auto Co., Cole 30; Crown Auto Co., Cadillac; Robt. C. Crowthers, Elmore; L. C. Dennison, Winton Six; Enger Motor Car Company, Enger; Franklin Automobile Co., Franklin; Ford Motor Car Co., Fords; Garford Truck Co., Garford trucks; J. K. Gilchrist, Demot, Detroit-Dearborn; Haberer & Company, Cino; Hanauer Automobile Co., Pierce-Arrow, Locomobile, Corbin, Jackson, Hellman Auto Co., Haynes, Cartercar; Herald-Reo Co., Reo; Herschede Motor Car Company, Courier, Stoddard-Dayton, Rauch & Lang Electric Rapid truck;. Jungclas Auto Co., The Mitchell, Palmer-Singer, Baker Electric; Leyman-Buick Co., Buicks; Lexington Motor Car Co., Lexington; Metal Stamping Co., wind shields; Middleby Auto Company, Middleby; Geo. C. Miller Sons Carriage Co., Stevens-Duryea; Milton Motor Cycle Co., motor cycles; Ohio Motor Car Co., Ohio; Olds-Oakland Co., Olds, Oakland; Oskamp Auto Supply Co., accessories; Paragon Refining Co., oils and greases; Payne Motor Car Co., Thomas; Peerless Buggy Top Co., tops; J. H. Ratliff Auto Company, Chalmers Hudson; Special Motor Vehicle Company, Schacht; Chas. Schlear Motor Car Company, Hupmobile, Velie 40, National, Warren-Detroit 30; Schumacher, Boye & Emmes, Knox, Knox truck; Sheldon Axle Co.; Smith-Eggers Co., Stearns; Speedwell Motor Car Agency, Speedwell; Standard Oil Co., lubricating oils; Staver Motor Car, Co., Staver-Chicago; Ferd. Stenger, Motor Cycles, Merkel, R. S. Pierce; J. S. Stevens, Matheson; Suburban Auto & Garage Company, Overland, Marmon, Marion; Toe Water Auto Supply Co., accessories; U. S. Motor Truck Co., truck; Warner Pole & Top Co., tops; Welland-Pope Co., Columbus Electric; Central Brass & Fixture Co. accessories; Craig, Wilson & Craig, automobile wheel.

Central Aisle of Cincinnati Show, with an Aeroplane Overhead and Stoddard-Dayton and Rapid in Foreground

E[redacted] on Washington's Birthday, the islands of Hawaii [redacted] extensive celebration, principally to celebrate the [redacted] existing between the islands and the country of [redacted] was the father. With success and a most en[redacted] each year, the importance of the celebration has gr[redacted], until now it is by far the most important event of [redacted] So much has it grown that all patriotic Americans [redacted] of miles make it their business to be there and take a part in "the doings." The decorations this year, as shown in the pictures above, were fully up to if not actually superior to those of any previous year. In the main, the floats in the parade were of a patriotic character, as for instance the American eagle protecting the globe, which was illustrative of the relations between the islanders and the government at Washington. Beautiful women and the magnificent flowers in which the islands abound were very prominent not alone in the floats but throughout the celebration. Prizes were offered for the most beautiful as well as the most grotesque cars and the same in the bicycle class. Similar to last year, the evening saw a very extensive masked ball, lasting into the wee, small hours.



LONGITUDINAL SECTION OF THE UNIT POWER PLANT OF THE 5-10-HORSEPOWER TWO-CYLINDER N. S. U. LIGHT CAR, ALTHOUGH FOLLOWING STANDARD LINES IN MOST RESPECTS, THERE ARE MANY NOVELTIES EMBODIED IN THE DESIGN. NOTABLE AMONG THESE ARE THE UNSYMMETRICAL CONNECTING RODS, THE PRESSED STEEL CLUTCH CONE AND THE CLUTCH OIL GUARD, THE METHOD OF OPERATING THE SERVICE BRAKE, THE CONSTRUCTION OF THE GEAR CASE, AND THE LONG BEARING OF THE CHANGE GEAR PRIMARY SHAFT

Careful Design Revealed in "N. S. U." Light Car

SIGNIFICANT of the change of heart experienced abroad in respect to light cars is the design of the 5-10-horsepower runabout recently brought out by the Neckarsulmer Fahrradwerke, a German firm whose product goes under the trade name of "N. S. U." Both in its general features and in its carefully worked out details this light car ranks with the highest-priced products of the German industry. The longitudinal section of the unit power plant on the opposite page (reproduced from *Der Motorwagen*), will serve as a sample of the general excellence and also as the illustration of a number of detail points.

As to the general features, the motor has two vertical cylinders 75 by 125 millimeters (2.95 by 4.92 inches), cast in a pair. The cranks are at 180 degrees, which, with vertical cylinders, means that the firing is uneven. It has been demonstrated, however, that engines of this type can be balanced to run as smoothly as could be desired for this service, and the type is a very common one in Europe. The wheelbase is 2.10 meters (about 82 3-4 inches) and the tread 1.15 meters (54 1-4 inches); the tires are 750 by 85, or about 30 by 3 1-2. The same chassis is also built with a four-cylinder block motor 60 by 100 millimeters bore and stroke (2.36 by 3.94 inches), but no drawings of this type are available.

The chassis frame is of pressed steel, both side members being straight, and is 3.035 meters long between the hanger eyes of the semi-elliptic springs. The width of the frame is 0.700 meters. The channel sections of the side bars are 35 millimeters wide and 70 millimeters deep in the middle, and the gauge of the metal is 2.5 millimeters. There are but two cross members, one in the middle and one in the rear; this would hardly be good design for American conditions.

The block power-plant construction has been carried out very thoroughly, including, besides the motor and change-gear, all levers and pedals and the steering column and gear. The base of the plant is built up of a number of parts. The crankcase is divided vertically and transversely between the two cylinders; this seems to be a relic of single-cylinder design and does not allow very easy access to the connecting rod big ends. The front half of the case has two integral supporting arms, which reach to the frame. From the rear half of the crankcase a casting extends around the flywheel and forms the front end of the change-gear housing. This housing itself is unusual; it is cylindrical in shape, being formed of a cylindrical shell with end pieces bolted in. It is hung from the middle cross member by two lugs. The whole is practically a three-point suspension, as the two gear-case lugs are comparatively close together.

One of the neatest details is the method of connecting up the foot-brake. This is at the rear of the gear-case, and of the expanding type. The brake shoes are spread by a cam at the bottom, and this cam is on a shaft which extends under the gear-case and reappears in the clutch well. Here it is provided with a horizontal lever, which is connected by a ball-jointed link with the lever on the brake pedal.

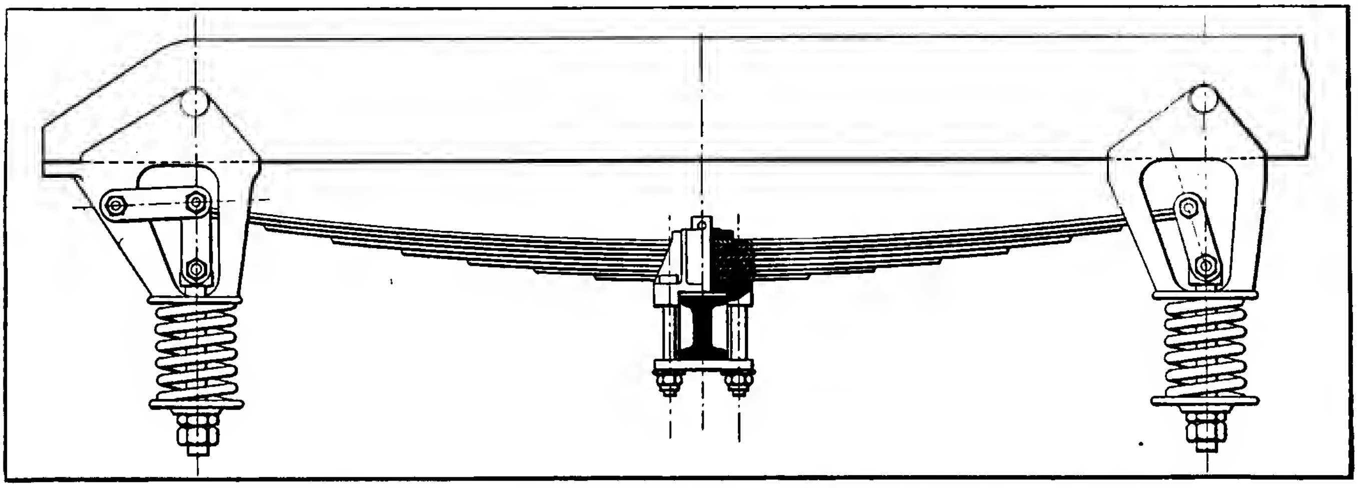
The clutch is a simple leather-faced cone, but differs from the usual design in having its cone stamped from sheet steel, instead of cast of aluminum. This is a cheaper construction and at the same time should give little, if any, increase in weight. At the same time the sheet steel has considerable natural spring, which should be useful in softening the clutch action.

The hand levers for the emergency brake and the change-gear are carried on an extension cast on the gear-case, and entirely independent of the frame. They are of the usual type; the brakes, on the rear hubs, are actuated by a wire cable which passes through the hollow shaft and provides for equalization. The steering column, which is raked at an angle of 45 degrees, is bolted on to the side of the crankcase. The throttle lever and the accelerator pedal are carried on the steering column at the point where it passes through the dash; the lever sets a minimum throttle opening, and the pedal is used to increase this temporarily as desired. The spark advance is fixed and requires no lever; thus the steering wheel is left unencumbered.

The magneto is placed transversely at the front end of the motor, and is driven by worm gears from the camshaft. This results in unusual accessibility.

Spring Suspension of German Truck

The illustration of the spring linkage of the Büssing truck, which appears below, is reproduced from the *Zeitschrift des Mitteleuropäischen Motorwagen-Vereins,* which recently published an instructive article on the steering and suspension of this car. The construction shown is used on the front springs only, for the protection of the motor and radiator, in the case of trucks, but is also used on the rear springs for omnibuses. The drawing is self-explanatory in so far as regards the design and operation. Another feature of the same car is the ball-joint of the steering link. The lever arm is split at its end into a sort of yoke, formed on the inside to receive the ball; when the ball is in place a pinching screw tightens up the yoke to hold it. The drag link has a yoke on its end which straddles the ball and is secured by a taper pin passing through it.



Combination of Semi-Elliptic and Coil Springs Used on the Büssing (German) Heavy Commercial Cars

Two Different Kinds of Magnetos

Editor THE AUTOMOBILE:

[2,191]—Will you kindly answer the following questions in your correspondence column: What are the advantages claimed respectively by makers and users of high and low tension magnetos? As I understand the matter, the low tension magneto requires a coil to transform the low tension current into a high tension current before it reaches the spark plugs, but the high tension magneto does not require any transformer. As simplicity and the elimination of unnecessary parts is the order of the age, why are not all magnetos made for high tension?

I feel that this is a question which will interest a number of your subscribers. C. W. FLEMING.

Toronto.

As showing just what the users and makers of the low-tension system claim for it, the two following extracts from the catalogs of makers adhering to this type are quoted:

"The 'Four' differs from the 'Six' mainly in that the ignition is by a particularly efficient make-and-break system, with alternating low tension Bosch magneto, geared direct to the motor. Only one main wire is needed to carry the current to all four cylinders. The motor can be started on the magneto by cranking."

And another says: "Our very simple and reliable low tension ignition, being the development and refinement of a type adopted by us in 1905 and used ever since. The simple electrical conditions established by the use of low-tension current exclusively, in combination with the exceedingly simple and effective mechanism, should make the strongest possible appeal to the purchaser who demands an ignition system that will be above all continuously reliable. Magneto is of the low-tension type, gear-driven. The simplest and consequently the most reliable instrument from which electricity can be generated. Because of its exceedingly simple electrical nature no peculiar electrical disturbances are met with, and the workmanship and special materials employed constitute an almost perfect insurance against trouble of any sort. Furthermore, if trouble is experienced, any good electrician can easily locate any trouble and correct it."

On the other side, although there are a greater number of parts used, and although the higher tension of the current passing through the wires makes for increased danger of short circuits, and other troubles, the fact of its well-nigh universal use speaks volumes more than lengthy argument could. Better results at high speed, and more particularly at low speed are claimed for the high-tension system; in fact, it is said that nearly all low-tension magnetos will not start the engine, batteries being relied upon for this purpose.

Thus, the argument sums up to simplicity, either real or apparent, on one side, and real proven reliability on the other.

How and Why of Steam for Power

Editor THE AUTOMOBILE:

[2,192]—I will be pleased to know what are the chief advantages and disadvantages of steam power plants for medium sized automobiles, similar to several well-known machines.

Peoria, Ill. L. MANSFIELD.

Steam has these disadvantages—many units, meaning large number of opportunities for trouble; necessity for an open flame in the presence of a highly inflammable fuel; low thermal efficiency of the whole system, length of time necessary for starting, necessity for keeping fire on or steam up while the machine is waiting, large number of controlling devices, absolute necessity for source of water supply at all times.

On the other hand, steam has many advantages; thus, the steam engine is very flexible, attaining a low speed, which is impossible with the gasoline engine; this flexibility allowing the maker to dispense with a transmission; moreover, it is readily reversible, doing away with reverse gears. In favor of the steamer, two or more years ago, its noiseless action was considered a big point, but that would hardly stand to-day, in the light of the very noiseless performance of the gasoline machines. To offset the open flame, ignition and electric current supply and timing devices are eliminated.

LETTERS INTERESTING

A Home-Made Automobile of Merit

Editor THE AUTOMOBILE:

[2,193]—You will find enclosed several pictures of an automobile which I have recently finished, doing all of the work myself. It was in several races and showed quite a little speed, its two-horse-power engine turning the wheels as high as 15 miles per hour. I take your magazine, "The Automobile," and get many ideas from it.

Greenville, O. RALPH W. DUNKLE.

The four pictures shown herewith depict Mr. Dunkle's maiden effort as an automobile manufacturer, the pictures being used just as received. The whole construction shows ingenuity, being somewhat different from any type of automobile now on the market. One picture shows the mechanic, from which it is apparent that he is not very old, all of which makes the situation more interesting. There really is no reason why other young Americans should not imitate Mr. Dunkle and build their own automobiles.

The man with mechanical tastes can get much more instruction and pleasure through building a car himself than from using one already made, even though he draws largely on the parts makers for his material. The maker of his own car is never at loss if anything should go wrong on the road, for, knowing every part intimately, he can locate the slightest fault; usually his foresight prevents its occurrence.

ANSWERED AND DISCUSSED

Black Lacquer for Brass

Editor THE AUTOMOBILE:

[2,194]—Will you inform me through the columns of "Letters Interesting, Answered and Discussed" where I can obtain a black lacquer suitable for the brass work and lamps of an automobile? I would like something with a gloss black finish that could be easily removed if desired. I have been a subscriber to "The Automobile" for less than a year, but find it very valuable. N. A. GOLD.

Stafford Springs, Conn.

Should one desire to make the lacquer himself, the following formula gives very good results: Dissolve one-half pound of best pale shellac in one gallon cold spirits of wine (so-called). When the shellac is dissolving, agitate it very thoroughly. After mixing, allow it to stand, then filter and bottle. It must be kept from the light as that would make it darker, this being a light lacquer. Now to make a dead black lacquer or finish for similar work, this may be colored black or the following receipt may be mixed instead: Fuse three pounds of Egyptian asphaltum. When liquid, add one-half pound of shellac and one gallon of turpentine.

The latter formula will give the dead black finish now so popular. The quantity of course may be regulated to meet the necessities of the case. For those who are tired of the incessant polishing necessary to keep brass lamps in condition, this lacquer will serve the purpose exactly.

Tire Inflation Pressure Discussed

Editor THE AUTOMOBILE:

[2,195]—What is the proper tire pressure to use for any given size of tire, that is, what I want to know is, is high pressure dangerous, rubber seems so dangerous a substance? Tire makers give pressures in their catalogs, but not all of them agree, some being lower than others. I would naturally use the lower pressures, but friends of mine say that this is wrong. What shall I do?

Albany, N. Y. CARL SPIRO.

Other things being equal, the highest safe pressure is the one to be used, and what the latter is, is hard to say, since manufacturers are now urging higher and higher presures. This they would not do unless their product were strong enough to stand the higher tension. Answering your question, the following advice from the Firestone Tire & Rubber Company is very appropriate:

"It has always been our policy to urge car owners to keep their tires fully inflated; thereby avoiding undue wear and saving their mileage guarantee," said an official of the Firestone Tire and Rubber Company, at the Auto Show.

"Remember that the tire manufacturer cannot make a pneumatic tire that will stand the work and give satisfaction unless the tires are kept inflated to the proper pressure intended for the different sizes of tires.

"Give them air and plenty of it—a pneumatic tire is intended to hold air. Air costs nothing—tires are expensive.

"The tire manufacturer guarantees his product under certain conditions. Meet him on the ground of proper air pressure in your tires and he will meet you on a better basis, if you have tire trouble due to other causes."

As for the variance in the tables of pressures given by the different tire manufacturers, it is probable that each manufacturer gives the pressures which he has found best adapted to his own particular make of tire; so get the table of the maker of your tires and follow that exclusively.

You are quite safe in putting all the pressure in your tires that you can possibly get in with an ordinary hand pump. Power pumps of course should be handled with more care. If you get in too much pressure it will make the tires hard riding and detract from the pleasure of using your car, but the danger of bursting them in this way is so slight as to be negligible.

Melting of Aluminum Alloys

Editor THE AUTOMOBILE:

[2,196]—Can you publish in "Letters Interesting, Answered and Discussed," information regarding the proportions of copper and other metals used in making the aluminum alloy used in transmission cases, motor cases and other automobile work? If possible give the methods used in melting, if it is best to cover the melting metal wtih a charcoal dust cover, or if other covers are used to this end. I have read somewhere, that the success of good aluminum castings was not obtained till a cover of some sort was used. The modern practice, I think will interest many of your readers. The old text books do not give much information about alluminum alloy. In Kent, it says that more than 11 per cent. aluminum with 89 copper will not make good castings, that they will be hard and brittle. The more modern work shows that this percentage has been very much increased. I will look for this with much interest. CONSTANT READER.

Jerome, Ariz.

Since one of the prime drawbacks of welding aluminum and aluminum alloys is its rapid oxidation, it would appear as if it were necessary to keep it covered during the melting process for the very same reason. Yet, as a matter of fact, many makers do not do so. In melting manganese bronze, which is much used in the automobile industry, a charcoal cover is a necessity, but this is because of the manganese content, manganese being a powerful and very rapid oxidiser. With white metals, white babbitts, and similar metals, the same advice is good, for the same reason, they all contain some—though little—manganese. In the near future a number of articles on materials of automobile construction will appear in these columns, and it is possible that something on the subject of aluminum may be included.

Discussing the Merits of the Point System

Editor THE AUTOMOBILE:

[2197]—I am much interested in your "Points of Merit in Selecting a Motor" in your issue of March 3, but fail to see how the civil service basis can be followed with enough accuracy by the purchaser of an automobile to enable him to check the motor with any degree of accuracy without elaborate and expensive tests which the ordinary buyer could not undertake. I also cheerfully disagree with your rating on many of the items. Numbering your conditions from 1 to 36, I fail to see how No. 1 could be determined by the purchaser of a motor until the motor had been worn out.

No. 3 lacks definite statements of conditions under which the cooling of the water should take place, unless you mean under the maximum power of the motor, in which case I should increase your points to 25.

In No. 4 thermal efficiency would be very difficult to determine.

In No. 5 it would be very difficult to obtain an absolutely straight line, and if such could be secured I should credit the motor 50 points.

No. 6—I would raise the points for accessibility, east of adjustment, to 50.

No. 7—Too difficult to determine.

No. 9—Perfection in this case should secure twice as many points.

Nos. 12 and 13 are neither quite clear as to where or when you would begin to remove pressure or depression. If you mean from the bsst practice the credit should be greater. If you mean from a normal exhaust or suction pipe, the points should still be increased.

In 16, 17, 18, 19 and 20 you credit the points for a satisfactory system, etc. This invalidates the points on this whole series, due to the indefinitsness of the word "satisfaction."

No. 24 I would eliminate. It is hardly the fault of the motor if the carbureter does not do its work, and you have already given a credit for proper carburetion.

The points on No. 25 seem entirely too high. A very good motor might require more than a quarter turn to start in zero weather repeatedly. I should cut this down to 25, also 26, for you have already provided for a tight compression.

In No. 28 you make the points for the motor depend on the car which it is to drive, which is not fair to the motor. This also applies to No. 29.

In No. 30 you make a big credit—100 points—for the size of the lubricating oil tank.

No. 31—as most motors have no exterior oil holes to be cared for it seems to me it should be eliminated.

No. 34 is a penalization of the motor for an item for which it is not in any way responsible.

No. 35 is evidently unfair to the large motor: if gasoline consumption is to be considered on the point system it can only apply to motors of a uniform horsepower, which also applies to No. 36.

Certainly this method of determining the value of a motor is very interesting, but I fear the amateur buyer or even the average engineer would be somewhat astonished at the result if he attempted to point up a motor from your basis. READER.

New York City.

In order to facilitate discussion, the suggested system as given in the March 3 issue of THE AUTOMOBILE is here repeated:

Points of Merit in Selecting a Motor

Conditions to be Considered	Points
1. For each year of service rendered	5
2. For a tight compression without an oil seal	10
3. For each 10 degrees reduction of the temperature of the cooling water below 212 degrees F. (to 170 degrees F.)	10
4. For each one per cent. increase in thermal efficiency	10
5. For a straight line torque performance up to 1,000 feet per minute of piston travel	20
6. For accessibility, ease of adjustment, etc.	20
7. For each reduction of 1,000 pounds per square inch of extreme fiber strain due to secondary moments at 1,000 feet per minute of piston travel, measuring the strain at any point desired on the section of the crankshaft	20
8. For tight cylinders under a hydrostatic test of 500 pounds per square inch	20
9. For perfectly round and parallel cylinder bores	10
10. For noiseless performance	25
11. For absence of packed joints	10
12. Per pound per square inch of back pressure removed	20
13. Per pound of suction depression removed	30
14. For a securely fastened flywheel	20
15. For integral or equally secure cams	20
16. For a satisfactory wipespark system of ignition	20
17. For a satisfactory system of high-tension magneto	20
18. For a satisfactory dual ignition system of ignition including a magneto	30
19. For a satisfactory double system of ignition, including magneto and a multi-coil	30
20. For a satisfactory double system of ignition with a magneto and a uni-sparker	30
21. For an ignition system in which the wiring is run in a proper conduit system	20
22. For a carbureter which will deliver gas of uniform density at all speeds of the motor	30
23. For a motor which can be assembled and taken down without having to use a special wrench or tool	20
24. For a motor which will not pop back in the carbureter under any condition of mixture	10
25. For a motor which will start on a quarter turn of the crank in zero weather repeatedly	100
26. For a motor which will start on the spark repeatedly after it is shut down for a period of 10 hours	100
27. For general appearance and exterior finish	20
28. Considering a given gear ratio; for a motor which will accelerate the car it is placed to drive, from a standstill to maximum speed in the shortest time	30
29. Considering a given gear ratio; for a motor which will drive the car it is placed to drive, up a ten per cent. grade, on "direct" at 1-4 (or better) of the best speed of the same car on a level	100
30. For a motor which is positively lubricated and capable of running 10 hours without having to be attended to (no addition of lubricating oil)	100
31. For a motor without any exterior oilholes to be cared for	40
32. For a motor which will not leak lubricating oil	10
33. For a motor which will not smoke	10
34. For an installation which is tight enough to exclude dust (a satisfactory system of pans)	100
35. For a motor which will deliver the power required on a gasoline consumption of one gallon for each ten miles	10
36. For each additional mile per gallon	10

No. 1—Should be taken to represent the number of years that a design may have been on the market. It is intended to represent the advantages which accrue from experience. The number of points given were limited, for the reason that a motor is not necessarily bad because it is new. At the same time, from the purchaser's point of view, he is bound to recognize the presence as induced by experience as against the risk which is taken in the purchase of any new device.

No. 3—Involves taking the temperature of the cooling water under the conditions as follows: (a) when the motor is running on a retarded spark with the car standing still; (b) after the car ascends a long, fairly severe grade; (c) under general running conditions. Obviously the water will boil if the temperature reaches 212 deg. Fahr., and incrustation is bound to form to the disadvantage of the system. It is even possible that a certain amount of incrustation will accumulate at temperatures above 170 deg. Fahr.; hence, the desirability of giving 10 points in favor of the motor for each 10 degrees below 212 degrees, and limiting the reduction to 170 deg. Fahr.

No. 4—As the correspondent states, it would be extremely difficult to establish by a purchaser, but it is indirectly possible to reflect thermal efficiency by noting gasoline consumption. The thermal efficiency is inversely proportional to the gasoline used.

No. 5—Presents an extremely important condition, and it may be that the chart line, when plotted, will be straight within the limit stated for very few motors. Such motors exist, however, and purchasers can well afford to examine into the characteristics of the motors they propose to purchase, with a view to ascertaining their performance with increasing speed. The performance will be best if the torque holds out.

No. 6—Certainly does represent an extremely important condition, especially to the motorist who confesses no skill as a mechanician. It would be interesting to hear from many motorists in relation to accessibility and ease of adjustment. The columns of The Automobile will be placed at their disposal.

No. 7—May be difficult to determine by any process which an unskilled motorist could bring to bear, but a reasonable retainer to an engineer of some competence will bring the information with sufficient certainty to make it worth while.

No. 9—Which refers to round and parallel cylinder boring, is of less importance at the present time than ever before, since the cylinders in nearly every automobile are ground, which process brings accuracy within allowable limits of tolerance. Even a variation of several thousandths of an inch, however, would not interfere with the working of a motor if the piston rings are properly placed.

Nos. 12 and 13—Represent a condition which is very serious, but any autoist can tell if the power of his motor increases enormously when the muffler cut-out is open; such an increase is direct evidence of back pressure; he would still be without a basis of comparison, but he would have his mind drawn in the direction which will result in advantage to him, even though he might not be able to put his conclusions into definite figures. No. 13 represents even greater trouble, but a motor which stalls with apparent ease may be suffering from the ills of excess depression.

Nos. 16, 17, 18, 19 and 20—Being based on satisfaction, represents nothing very definite, as the correspondent states. At the same time, the fact that ignition is included in the system is a warning to the prospective purchaser that he has something to investigate, and if he does not know from his own experience what constitutes satisfaction, from the ignition point of view, he might consult someone who does. At all events, this is a matter which will stand discussion.

No. 24—The carbureter is not at fault for popping back; the trouble comes from having a poorly designed intake manifold. Popping back will not transpire if the rate of travel of the gas in the manifold is greater than the rate of flame travel within the molecular structure of the gas.

Nos. 25 and 26—We would like to hear from other motorists in relation to these points.

Nos. 28 and 29—The point system as originally devised was intended to refer to a motor as it relates to an automobile. The method of utilizing the power under the circumstances must be taken into account. If the gear ratio is not in accord with the power of the motor, considering the car construction and weight, the motor may be capable of propelling the car on a hard, level road, but it may not do good work on grades.

No. 30—It does look like offering a premium for a decent-sized oil tank, but the importance of proper lubrication is sufficient to demand a relatively large tank, and the means by which the lubricant will be fed to the points to be lubricated with precision and certainty. Flooding a bearing may keep it in good order as long as the oil holds out, but if the flooding method is employed the tank must be big enough to supply the requisite quantity of oil for a reasonable length of time—10 hours would scarcely be too long.

No. 31—If, as the correspondent states, motors are not hampered with exterior oil holes, then it will not be necessary to give this matter consideration. It will be just as well, however, to glance over the power plant during selection, and make sure that provision for oiling is complete, in the absence of these exterior methods of feeding oil.

No. 34—It is not believed that dust pans would be used at all were it not for the presence of motors. One of the duties of the dust pan is that of compelling air to enter through the radiator; this is when the fan is in the flywheel. Even with the best possible construction, it is customary to allow for a leakage through the dust pan of one-third of all the air which the flywheel fan can handle.

No. 35—The fuel consumption may be measured on a basis of ton-miles, which is the custom in economy runs; but the practice of overloading the automobiles during these runs induced a false economy, which is rarely ever equalled under normal conditions on the road, considering an autoist of average skill. It also seems to be true that automobiles take about a certain amount of gasoline almost without regard to the types of motors employed. There are exceptions, of course; but the fact remains that 10 miles per gallon, considering an ordinary touring car, is a fairly common figure, and 12 to 14 miles per gallon is reached when the cars are in rather good shape, and handled under average conditions. This matter is open for discussion.

The Editor does not believe that this point system of selecting automobiles can be reduced to a level of good practice without being refined, and refinement will come as the result of discussion. The experiences of autoists should be of excellent value in this connection, and it is hoped that they will come forward and give intending purchasers the benefit of their experience.

If the motor can be examined in this way by an intending purchaser, then the same principle may be applied to the whole automobile, and even if the point system fails to satisfy the whole situation, it will at least compel intending purchasers to examine the cars in which they take an interest, with much more care than they might otherwise be induced to do.

Coming Events in the Motoring World

Mar. 15-19........Syracuse, N. Y., State Armory, Automobile Show, Syracuse Automobile Dealers' Association.

Mar. 15-19........Bridgeport, Conn., Automobile and Aeronautic Show, Bridgeport Automobile Dealers' Assn.

Mar. 17-19........Louisville, Ky., Automobile Show, Louisville Automobile Dealers' Association, in the Louisville Armory. Hubert Levy, Secretary.

Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo, Launch Club. D. H. Lewis, Mgr., 760 Main St.

Mar. 21-28........Denver, Col., Convention Hall, Denver Motor Club's Annual Automobile Show.

Mar. 26-Apr. 2...Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

Mar. 26-Apr. 2...Montreal Automobile and Motor Boat Show, Official Motor and Sportsmen's Show Committee of the Automobile and Aero Club of Canada, in the Coliseum. E. M. Wilcox, Manager, 123 Bay St., Toronto.

Apr. 11-16........Elmira, N. Y., State Armory, Automobile Show, Elmira Chamber of Commerce.

Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.

Jan. 17-24, 1911.New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.

Feb. 18-25, 1911..Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

Mar. 19..........Altadena, Cal., Hill Climb, Licensed Motor Car Dealers' Association, Los Angeles, Cal.

Mar. 20..........Hill Climb, San Francisco Motor Club, San Francisco, Cal.

Mar. 22-25........Daytona, Fla., Speed Carnival, Florida East Coast Automobile Association.

Mar. 28-29........Savannah, Ga., Endurance Run to Jacksonville, Fla., Savannah Automobile Club.

Apr. 8-10 & 13-17.Los Angeles, Cal., Inaugural Meet, Motordrome.

Apr. 30-May 2...Philadelphia, Roadability Run to Atlantic City, Quaker City Motor Club.

May 2............Flag to Flag Endurance Contest, Denver, Col., to City of Mexico.

June 11..........Wilkesbarre, Pa., Annual Hill Climb Up Giants' Despair, Wilkesbarre Automobile Club.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

Fire-fighting has advanced in many ways and there is ample reason for believing that the situation is well in hand from almost every point of view. Automobile methods are slowly but surely creeping in, and from now on it is scarcely to be believed that municipalities will indulge in the purchase of any more of the obsolete equipment which is likely to be offered. This field, now that it is awakened, will prove as a boon to makers of automobiles; it will give them an outlet for their surplus energy, and, in the event of overproduction in the pleasure vehicle line, it will serve, to some extent, as a safety valve for the industry. The conservatism of some of the municipal authorities as it is reflected in the relation of the purchasing representatives to the class of equipment selected, is now more favorable to the automobile side of the situation, and the actual merit of this class of equipment, of which there is not the shadow of a doubt, will soon bring to bear the potential weight of utility of a high order. That insurance exchanges will take to the automobile is easily reflected from the fact that fires will cease to so heavily draw money from their coffers, and it is the saving of money that counts for them.

Lubrication has its many angles; it is not limited to the mere process of floating bearings, nor is it usually given credit for all the good that it is employed to accomplish. Friction is represented by the energy dissipated in a bearing, and the total loss is lessened if the coefficient of friction is lowered. It is the function of lubricating oil to offer a low coefficient of friction and to shear in its section rather than to wipe off of the bearing surfaces. The energy which should be transformed into heat under working conditions, according to this theory, is that represented by the parting of the molecular structure of the lubricant rather than the rubbing of metal to metal which would transpire were the parts to contact, as they would in the absence of the lubricating oil.

It is the duty of lubricating oil, in addition to maintaining a condition of fluid friction, to seal up the journals and keep the silt of the road from penetrating and adding its abrading qualities to complicate the situation. Besides accomplishing these important duties, the oil acts as a "bumper" and it is quite as effective in this regard as a bumper on a freight car, or a shock absorber on an automobile. The life of an automobile, according to this way of reasoning, may be prolonged by the proper use of lubricating oil.

Cylinder lubrication is much misunderstood in all probability, and frequently, when carbon formations are charged to lubricating oil, they are due to excesses of gasoline which is partially burned in the presence of less than the proportional amount of atmospheric air to deliver to the requisite quantity of oxygen. If cylinder oil does lie at the bottom of the trouble, to the exclusion of carbon from gasoline, then there is an explanation wanting. Is it due to the difference between the flash point of the oil and the heat required to inflame the carbon in the oil, that carbon is formed? If so, the answer must be found in one of two ways, i.e., eliminate the carbon, or, elevate the flash point of the oil.

The point system, as originally suggested in THE AUTOMOBILE, for use in the selection of cars by relatively inexperienced autoists, is probably in need of much discussion, rather with the hope, perhaps, that it will ultimately be sufficiently refined to serve the intended purpose. With hundreds of automobiles to select from, the man who goes after his first car is confronted with a serious problem, which to him is all the more momentous if the size of his purse is in sparse conformity with the dimensions of his aspirations. It is a serious matter to make a mistake under such conditions, but it is annoying to a man of means to find himself in full possession of that which does not live up to his expectations.

In any event, even assuming that a system of examination cannot be perfected sufficiently to serve every end, it will nevertheless afford sufficient advantage to warrant its use on the ground that it will compel the purchaser to do two things, i. e. (a) consider his own requirement at some length, (b) ascertain by personal examination something of the makeup of the automobiles which would seem to conform to his expectations. In nine cases out of ten, men who have trouble with the cars they select are at fault in the main, because they have one idea in their head, and purchase another through the influence of their pocketbook. Disappointment is their sure, if not just, reward. They cannot by any manner of reasoning attach blame to the maker of the automobile so selected, and it is believed that the point system would help them to unify their thoughts with their actions.

BOSTON DEALERS FORM A LICENSED ASSOCIATION

NEW YORK DEALERS' ASSOCIATION TAKES ROOT--SIXTY MAKERS REPRESENTED AT PRELIMINARY BOSTON MEETING--EVERY MEMBER MUST REPRESENT AN A. L. A. M. MAKER

ONE of the interesting angles of the late Boston Show was represented in the coming together of the Boston agents for automobiles manufactured under the Selden Patent license. This idea which was first put into force by the New York dealers was enthusiastically taken up by the agents in Boston of sixty Selden makers. The new organization is being incorporated under the laws of Massachusetts, and will have for its main purpose the furthering of the Selden Patent interests as they relate to Boston agents for automobiles.

At the preliminary meeting the little formalities were disposed of most readily, because of the experience which was gained through the efforts of the New York dealers to organize, and the officers of the new Boston Association were slated as follows: President, John H. MacAlman, Columbia and Stearns; vice-president, J. S. Hathaway, White; treasurer, F. A. Hinchcliff, Winton; Secretary, Chester I. Campbell.

The directors include the above-named officers, and J. W. McGuire, of J. W. McGuire & Company, Pierce-Arrow; J. W. Bowman, of J. W. Bowman Company, Stevens-Duryea and Everitt; E. E. Wing, Marmon; S. P. Underhill, of the Underhill Company, Knox; C. F. Whitney, Park Square Auto Station, Alco and Stoddard-Dayton; E. D. Gilmore, Whitten & Gilmore Company, Chalmers and Hudson.

The Boston situation is such that about 40 dealers handle all of the licensed automobiles there represented. To show how completely the idea of association takes among them, it is only necessary to mention that 36 came in during the first meeting.

While it is not positively asserted that next year's show will be confined to licensed automobiles, it is quite generally understood that Manager Campbell will have charge of the show, in which event it is quite evident that his efforts will be confined to the character of automobiles that support a license tag.

A. L. A. M. LEGAL TECHNICALITIES UNTANGLED

DELAYED action of the A. L. A. M. has been due to some legal entanglements, due to the changing of the name of the Electric Vehicle Company to the Columbia Motor Car Company. Counsel for the A. L. A. M., Betts, Sheffield, Bentley & Betts, have advised their client (the A. L. A. M.) that they have secured from Judge Hough an order to show cause why the petition should not be granted and the supplemental bill filed in the matter of the Ford suit and the suit against Panhard & Levassor and Neubauers.

The order to show cause is returnable April 1, and defendants must serve complainant's counsel with answering papers on or before March 28. The order also provides that they must show cause why their time for pleading should not be limited to April 11, and why the time for taking the testimony should not be limited, apportioned, and the scope of the testimony limited to the transfer of the interest involved.

It has been claimed by many who profess to be on the inside, that the A. L. A. M. is holding back any action it might contemplate in its fight against independents until this legal formality is completed, and in view of the near settlement of this matter, it looks as if the outsiders will soon be in a position to learn of the real attitude of the licensed makers of automobiles.

FLANDERS DENIES RUMOR OF MERGER

When J. P. Morgan & Company purchased the E-M-F Company and paid $4,800,000 for the outstanding stock (not counting the stock which is held by the Studebakers and Frederick S. Fish, amounting to 30,817 shares in the aggregate), there was talk of a big merger and the situation looked threatening. It was stated at the time, in The Automobile, that there had been a transfer and that $5,000,000 was involved, but that the particulars were not to be had.

That the market has heard the last of the story is scarcely to be taken for granted but the time is not ripe for a big merger. Just now the papers are excited about the profits which were taken by the former owners of the E-M-F control and it is claimed that the plant, at Detroit, will be enlarged and that the new board of directors voted $100,000 for the purpose.

The real situation is that the fight of the Studebakers with the E-M-F has been disposed of by the purchase.

THREE MORE SELDEN PATENT LICENSEES

According to an announcement of the Association of Licensed Automobile Manufacturers made public Tuesday, three more companies have been licensed to manufacture automobiles under the Selden patent. They are the Speedwell Motor Car Company, of Dayton, O., which makes the Speedwell; the Courier Motor Car Company, also of Dayton, making the Courier, and the Ohio Motor Car Company, of Cincinnati, making the Ohio.

CLEVELAND MAY HAVE LICENSED DEALERS

Hardly had the Cleveland show season come to a close with the winding up of the Cleveland Automobile Club's exhibit, which was the second of the year, when the dealers started to discuss the show prospects for next year.

Until there is a larger place available than Central armory, two shows will be absolutely necessary. There is some talk of following the New York plan and having one for pleasure cars and another for the commercial vehicles.

Then again there is a plan on foot for the organizing of the dealers in licensed machines. If this organization is perfected, the shows in Cleveland next year will be held separately by the licensed and unlicensed dealers. The latter also promise to organize if the former do.

BRADLEY JOINS U. S. MOTOR COMPANY

L. M. Bradley, who for the past three years has been advertising manager of the American Motor Car Manufacturers' Association, and assistant to former General Manager Alfred Reeves until the latter accepted the general management of the Association of Licensed Automobile Manufacturers, has joined the United States Motor Company, the recently organized $16,000,000 corporation which has already absorbed the Maxwell-Briscoe Motor Company and the Columbia Motor Car Company. He will act as director of advertising and publicity. In his new position Mr. Bradley will direct an extensive campaign.

MAXWELL-BRISCOE DELVING DEEP IN REAL ESTATE

AS a further evidence of activity involving the Maxwell-Briscoe interests, attention is called to current reports referring to the transfer of the property known as the Tichenor-Grand Sales Stables and Riding Academy, on Sixty-second street just west of Central Park West. The property comprises a seven-story brick and stone building, with a frontage of 75 feet at 3-7 West Sixty-first street, with a depth of 210 feet, which runs through to Sixty-second street. It is claimed that this property is worth $600,000 in round numbers, and while it is reported that the Maxwell-Briscoe Company will occupy a considerable portion of the building after it is fitted out, it is said that other companies will be afforded accommodation within the same building. The Maxwell-Briscoe Company has a large building at the northeast corner of Broadway and Sixty-fourth street, and a further acquisition on this enormous scale is at the bottom of rumors of further efforts in the merger line.

STUDEBAKER DENIES INDIANAPOLIS RUMORS

It is understood by those who are familiar with the automobile situation that some interest is offering inducements to certain of the makers of automobiles in Indianapolis, the character of which would seem to indicate that there is a definite and well organized attempt on the part of some cluster of automobile making investors to bring about a merger on a large scale. William R. Innis, president of the Studebaker Brothers Company of New York, and a member of the board of directors of the company of the same name, with its plant at South Bend, Ind., goes to some pains to deny that the Studebaker interests are in this move. Naturally, the Studebaker Company would be regarded as likely to be in a move of this character, in view of the acquisition of the E-M-F plant by J. P. Morgan & Company for the Studebaker account; it is a habit the public has of interpreting the law of probabilities, basing their prognostications upon the efforts in the past. Therefore the automobiling public watches these concerns for new developments.

S.A.E. SUMMER MEETING WILL BE AT DETROIT

Discussion in relation to the doings of the Society of Automobile Engineers leads to the conclusion that the Summer meeting will be held in Detroit, with dates which will overlap the Grand Rapids Road Race, which has been sanctioned by the A. A. A., with precise dates to be filled in, with the understanding, however, that the middle of July is a good approximation. The society is now assuming active proportions, and President H. E. Coffin is handling the matter with a vigorousness which promises extra results in all directions. The Summer meeting is always one of the greatest importance to the society, and Detroit seems to be the most favored place for this year. Certainly Detroit offers an unusual number of attractions, among which it is almost unnecessary to mention the great aggregate of plants which are within trolley car reach of the center of the city, and it is fortunate that automobile makers there offer every facility and keep open shop for society members. The exact date of the meeting is yet to be fixed.

MORGAN MERGER RUMORS UNCONFIRMED

Despite the persistence with which rumormongers continue to discuss the possibility of a combination under the skillful guidance of J. P. Morgan & Company, involving Maxwell-Briscoe, United States Motor Company, General Motors Company and Studebaker, which rumors are bolstered up by statements emanating from Indianapolis and elsewhere to the effect that they have had opportunities to participate, it is impossible to discover any authentic source of information which would lead to the conclusion that any such matters are beyond the realm of speculation. In the meantime it is inexpedient to disregard the existence of activity by way of real estate purchases and other problems of moment which here and there float to the top and indicate to the observer of acumen the rumblings of a substantial volcano which are likely to lead to something more definite in the near course of events.

LOS ANGELES RACES WERE OPEN TO ALL

Los Angeles, Cal., Mar. 12—After being threatened with the recall of the sanction granted by the A. A. A., the Los Angeles Motor Racing Association, which is controlled by the licensed dealers' association, withdrew its decision to restrict the races at Ascot Park to licensed cars. Several entries were cancelled by the disgruntled licensed dealers, but the racing nevertheless was spirited and interesting.

One record was broken, Livingstone on a Corbin reducing Burman's 50-mile mark to 50:26 1-5, in a race in which he defeated Harroun and Matson on Marmons, Free on a Ford, Odell on a Pennsylvania, Edecott on a Cole and Seibel on a Sterling. Livingstone drove the first 20 miles in 20 flat. Harroun won two five-mile races and one ten-mile.

OFFICIAL SANCTIONS GRANTED BY A. A. A.

Sanction No.	Date of Event.	Kind of Event.	Promoter.
131.	March 22, 23, 24	Beach races.	Fla. East Coast Auto Ass., Daytona, Fla.
132.	April 8, 9, 10	Track.	Los Angeles Motordrome.
133.	April 13	Track.	Los Angeles Motordrome.
134.	April 15, 16, 17	Track.	Los Angeles Motordrome.
135.	March 12 to 16	Match race and speed trials.	Fla. East Coast Auto Ass., Daytona, Fla.
136.	May 5, 6, 7	Track.	Atlanta Auto. Assn.
137.	March 20	Hill climb.	San Francisco Motor Club.
138.	March 26	Hill climb.	Atlanta Journal & Fulton Co. Automobile Club.
139.	April 30, May 1, 2	Roadability run.	Quaker City Motor Club.

BUYERS OF VELIES WILL BE PROTECTED

The Velie Motor Vehicle Company has notified its selling agencies, as well as the owners of Velie cars, that all its product will henceforth be guaranteed not only against defects in material and workmanship, but also against all damages arising from patent litigation. The form includes the following clause: "We further agree to indemnify the purchaser of this car against loss through patent litigation arising in connection with the purchase of this machine by reason of alleged patent infringement." The Velie company further states that its full financial strength is behind this guarantee, and that any attempt to antagonize dealers in or owners of Velie cars will be met with prompt and decisive action.

CRESCENT ATHLETIC CLUB HAS AMBITION

The Crescent Athletic Club's challenge for an automobile team reliability contest of ten or twelve cars on a side, to be held over Long Island roads on some date in the Spring for the trophy offered by A. R. Pardington, has been accepted by the Long Island Automobile Club at a special meeting of their contest committee. That committee and the automobile committee of the Crescent will meet this week to take up and thoroughly discuss the matter.

FOUR NEW COMPANIES AND MUCH BUILDING IN DETROIT

DETROIT, March 14—The latest recruit to the long list of makers in the automobile manufacturing field is the T. H. T. Motor Co., which, capitalized at $100,000, plans to manufacture a four-cylinder touring car on designs of a sample which is listed as one of the assets of the company. Announcements of factory space and operating staff are expected shortly.

The Carhartt Company is another recent addition to Detroit's string of automobile manufacturers, having just filed articles of incorporation, with a capital stock of $500,000, of which $300,000 is common and the remainder preferred. Hamilton Carhartt, Sr., famous as a manufacturer of clothing, is president of the company, and Hamilton Carhartt, Jr., will act as vice-president. Ralph C. Lewis will have charge of the mechanical department, and will also be secretary. A factory has been secured at 1524 Jefferson avenue, and deliveries of the car, which will sell at $2,250, will begin in August.

The Sibley Motor Company, capitalized at $80,000, has been incorporated at Detroit. A four-cylinder 20-horsepower roadster, to sell at $850, will be produced. An experimental car has been in use for nearly a year with good results, and it is the intention to secure a factory at once and begin manufacturing this season.

The Cass Motor Truck Company has been incorporated with a capital stock of $300,000 to manufacture automobile trucks. W. Ferguson is the principal stockholder of the new concern.

Much building is now going on, and nearly all of it of a permanent character. The Cadillac factory is so cramped for quarters that the body-finishing department has been moved several blocks to the Detroit riding academy, which has been transformed into a finishing plant. Some construction work already is in progress on the site of the firm's new factory, and several of the carbarns which occupy the property recently purchased, adjacent to the plant, are in use, pending the time when they can be replaced with the factory's new buildings.

The Chalmers company broke ground Monday for a new building, 150 by 50 feet, of one-story construction, to be used for the block-testing of motors and the heat-treating of steels. The building will be of cement and steel exclusively, not one bit of inflammable material being employed in its construction.

The new factory of the Hudson company, located almost directly across Jefferson avenue from the Chalmers, is progressing rapidly, the walls being already up. The Watt Motor Car Co., which has been occupying temporary quarters on Porter street on the west side, has purchased a plot of property in Hamtramck and plans to have a factory built in the early Spring to enable it to complete its manufacturing schedule, which calls for 600 of the 1910 models. The Van Dyke company has bought the Lowrie Lumber Company property, at Junction and Leavitt, and has broken ground for a factory. The Owen Motor Car Company is now installed in its factory on East Boulevard, near the Packard plant, and is hard at it, working on the 500 high-power cars which will be manufactured this year.

REEVES DIFFERS WITH KNIGHT'S ATTORNEY

In THE AUTOMOBILE issue of February 17 Charles Y. Knight, through his attorney, discussed the merit of the Reeves Re-Issue Patent No. 12,991, which the Packard Motor Car Company has a license to use, and according to the Knight version of this re-issue, it is of little value because in the process of obtaining a re-issue the claims were enlarged and the scope of the patent was so altered that as a re-issue it is in conflict with court rulings bearing upon this subject.

It is now claimed by the owners of the Reeves Re-issue Patent, that Dugald Clerk in his discussion of the situation failed to consider all the facts and reached erroneous conclusions in consequence. The Reeves representatives go on to say that it is true of the re-issue that it shows several different arrangements of valves for compressors, motors, etc., including steam engines, and an examination of the re-issue will of course show that it differs in material respects from the preamble and claims as originally included. The Reeves interests are authority for the statement that it is entirely practicable to employ the essential elements of the valve structure, shown and claimed by the patent, in a gas engine. The Knight attorneys, on the other hand, base their contentions upon the rulings of courts, some of which were given in THE AUTOMOBILE, and they stoutly maintain that the Reeves Re-issue is not in conformity with these rulings. It is anticipated that opportunity will be afforded the lawyers on both sides of this situation to exercise their talents and acumen.

KEEN INTEREST IN ELMIRA'S SHOW

ELMIRA, N. Y., Mar. 15—The Elmira Chamber of Commerce is to conduct an Automobile Show between April 11-16, inclusive, in the New York State armory. All of the local dealers and those agencies that cover the Elmira territory are manifesting a keen interest in the show and the present indications are that we will have a very fine exhibition.

Handsome electrical and other kinds of decorations will be indulged in and band concerts will be held afternoons and evenings. There will be interesting displays in the nature of aeroplanes.

OLDFIELD ADVERTISES UNOFFICIAL RECORD

Barney Oldfield's publication of an unofficial record made by his Benz car on Ormond Beach has drawn a sharp rebuke from S. M. Butler, chairman of the A. A. A. contest board. The report was that on Sunday last the Benz, with Barney at the wheel, covered a mile faster than the world's record. When this was made public Chairman Butler immediately wired Oldfield that no so-called records must be published unless made with due timing supervision and sanction. This point is expressly covered by the rules of the A. A. A. Chairman Butler also withdrew the sanction granted for the Oldfield-De Palma match, which has been called off, and no official trials can be held on Ormond Beach until the meet of the Florida East Coast Automobile Association, March 22 to 25.

CROXTON-KEETON PLANS BIG INCREASE

MASSILLON, O., March 7—The Croxton-Keeton Motor Company is planning to increase its capital stock from $300,000 to $750,000, of which two-thirds is to be common and one-third preferred 7 per cent cumulative. A committee appointed by the local board of trade to investigate the standing of the company has made a favorable report, and the board will now stand back of the plan. It is believed that the additional capital can be secured in Massillon without the least difficulty.

The company now employs 200 men, and its entire product for 1910, estimated at 600 cars, has been sold. If the present plans are put through the capacity will be doubled. It will be the policy of the management henceforth to specialize to a considerable extent on commercial cars, especially taxicabs.

REGISTRATION OF RACING OWNERS

The following drivers have registered with the Contest Board: Registry: 1. George H. Robertson. 2. Ralph De Palma. 3. Frank L. Lescault. 4. David L. Bruce-Brown. 5. Ralph K. Mulford. 6. Louis A. Disbrow. 7. Edwin H. Parker. 8. Willie Haupt. 10. William Knipper. 14. Harry H. Cobe. 15. Jack Lavin. Amateur Driver: 1a. Caleb S. Bragg.

FLAG TO FLAG CONTEST IS RAPIDLY ASSUMING FORM

MANY of the manufacturers are looking toward the Flag to Flag contest which is to start from Denver on May 2 to the City of Mexico, a distance of 2,400 miles, which will be covered in 21 days, approximately 114 miles per day with 8 hours running time. The contest will be run under the sanction and rules of the A. A. A. Several handsome trophies will be given, the principal one by G. A. Wahlgreen, of Denver, who is manager of the race. G. A. Blanchard, of Denver, assistant manager, is in the East now calling on the factories explaining and securing entries. This run involves many novel features, and being in an entirely different country from any event yet promoted, should be of keen interest to the factories who are looking for territory in which to sell their cars.

Westerners are more universally wealthy than the Easterners, and have adopted the automobile more as a necessity than a luxury. Ranchmen who have thousands of acres to oversee can save many hours of their time, and can be in closer touch with their lands and conditions than by the old mode of riding horseback. The natural roads are generally very good; of course in the country there are many bad places, but it is understood that the trail of this tour is not hazardous, considering the long distance. The Business Men's Associations and Chambers of Commerce in all the cities that the tour goes through are making preparation for the entertainment of the tourists upon their arrival. The president of Mexico is taking a personal and keen interest in the event. Probably no body of automobile men will be more royally received and entertained than those who accompany this tour when they arrive in the City of Mexico.

In the City of Mexico there are probably 8,000 automobiles, 75 per cent of which are of foreign make. This seems very strange owing to the prominence of the American manufacturers, and this republic being a sister country. It is probably due to the fact that American manufacturers so far have found an outlet for their products in America, without being compelled to seek this new outlet. However, this condition will not always prevail in America, and it will not be long before they will look upon this country with indifference.

Everything is being looked after for the convenience of the tourists through the barren country. A Pullman train with dining car service will be made up at Denver and will accompany the tourists the entire route, stopping at each control at night, where the drivers and representatives from factories will be able to sleep and eat with all the comforts of home.

The management is trying to secure a special rate from the City of Mexico to New York for shipment of the cars in bulk so that they can hold a parade in New York. An automobile show in the City of Mexico is being arranged for the week following the arrival of the cars in that city where all the contesting cars will be exhibited free. If the show proposition does not go through they will have the "bull ring" in which to exhibit.

Needless to say, the car that makes this tour successfully and with a perfect score will prove to the manufacturers and the people that it is a mechanical masterpiece. The expense of the tour is not as great as one would imagine on a careless thought. It is estimated that $1,500 to $2,000 will take a car with two men from its factory through the tour and return, and considering the eagerness and interest which is displayed in the section of country which the tour will go through this expense will make a very profitable investment.

Manager Wahlgreen and his assistant Mr. Blanchard are well known to the automobile industry, and they have been connected with the automobile shows and races in Denver for the past eight years. There is no doubt but that they will look after all convenience and details for this contest to the satisfaction of the contestants.

The entries for this event will close April 15, the Premier entry being No. 1. A conservative figure of the cars which are expected to start is from 35 to 40. Many manufacturers are awaiting an interview with Mr. Blanchard before making their entries.

AUTOMOBILE ASSOCIATION ORGANIZED TO DEFEND MEMBERS

A NEW automobile association, unincorporated, has been formed in the State of New York for the purpose of furnishing attorneys to defend its members in New York and throughout the United States. This association has been organized by representative automobilists and has made application for membership in the New York State Automobile Association. A work similar to that to be carried on by this association, has been performed by the Automobile Legal Association of the New England States, which has its headquarters in Boston, Massachusetts. The New York Association which is known as the Automobile Legal Association of New York is a separate and distinct organization, and is not, as has been mistakenly stated, a branch of the New England Association.

The officers of the Automobile Legal Association of New York are: H. Walter Webb, president; Frederick H. Elliott, secretary, also secretary of the American Automobile Association, and William A. Thibodeau, general counsel and treasurer.

The organization possesses an Advisory Board of the following persons: H. Walter Webb, Guy R. McLane, Frederick Wm. Hill, S. M. Butler, A. B. Maynard, C. Arthur Benjamin, Edwin L. Thomas, Gorton Wm. Allen, F. A. Hodgman, Oliver A. Quayle, Dr. Edward G. Cox, H. A. Meldrum, Bert Van Tuyle, Frank G. Webb.

The benefits and privileges of the association as stated in its prospectus are as follows:

First—Its subscribers are furnished the services of its attorneys to defend them in any suit brought against them for injury to animals or damage to property (except to automobiles), where personal injuries are not an element in the case.

Second—Its subscribers are furnished the services of its attorneys in defending them, their chauffeurs, or any person operating their automobiles for any alleged violation of the automobile laws in any of the States.

Third—Its attorneys will appear for its subscribers in court.

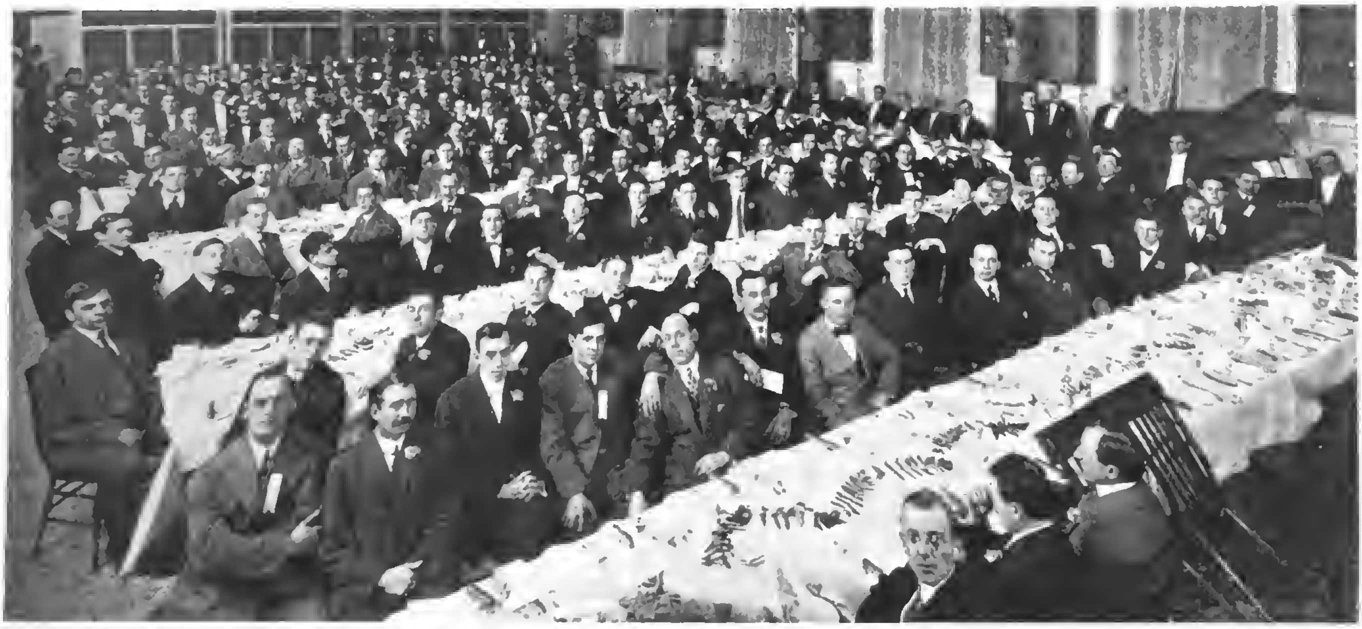
Fourth—Its attorneys will furnish its subscribers legal advice as to their rights and liabilities as automobilists.

Fifth—Its attorneys will protect the rights of its subscribers and their chauffeurs before the licensing authorities of the various States previously mentioned.

Sixth—Subscribers are furnished without charge with a copy of the A. L. A. Hand Book for each year.

Seventh—All subscribers are furnished a plate bearing the initial letters of the association.

Many automobilists carry liability insurance protecting them against liability for personal injuries, therefore this association does not enter this field, its main object being to relieve automobilists from the expense and trouble resulting from the trivial difficulties usually experienced on the road, but which cause great annoyance. Members of the association are relieved from paying all legal fees and expenses for the membership fee of $10 annually. The offices of the organization are at 50 Church street, in the Hudson Terminal Building, New York City.



Banquet of the Chicago Motor Club, Which Was Attended by Many Prominent Automobilists

HAWKEYES HOLD GOOD SHOW IN IOWA'S CAPITAL CITY

DES MOINES, IA., Mar. 14—The show which closed here last Saturday was not only successful from an artistic standpoint, but also, what is more to the point, from the view of the business men, in the matter of sales. Opening in the Coliseum on March 5, under the auspices of the Des Moines Automobile Dealers' Association, the success of this, the first annual show, has been a source of gratification to all concerned, particularly to the hustling committee whose work was so well rewarded. The decorations were not extensive nor expensive, consisting simply of sign boards raised upon pillars, upon which signs the exhibitors names were painted. The posts were partly hidden by garlands of smilax and other greens, while a few strings of flowers were used to separate the exhibits. The show as a whole reflected great credit on its organizers.

Exterior of the State Armory at Syracuse, Which Is Occupied by the Automobile Show This Week

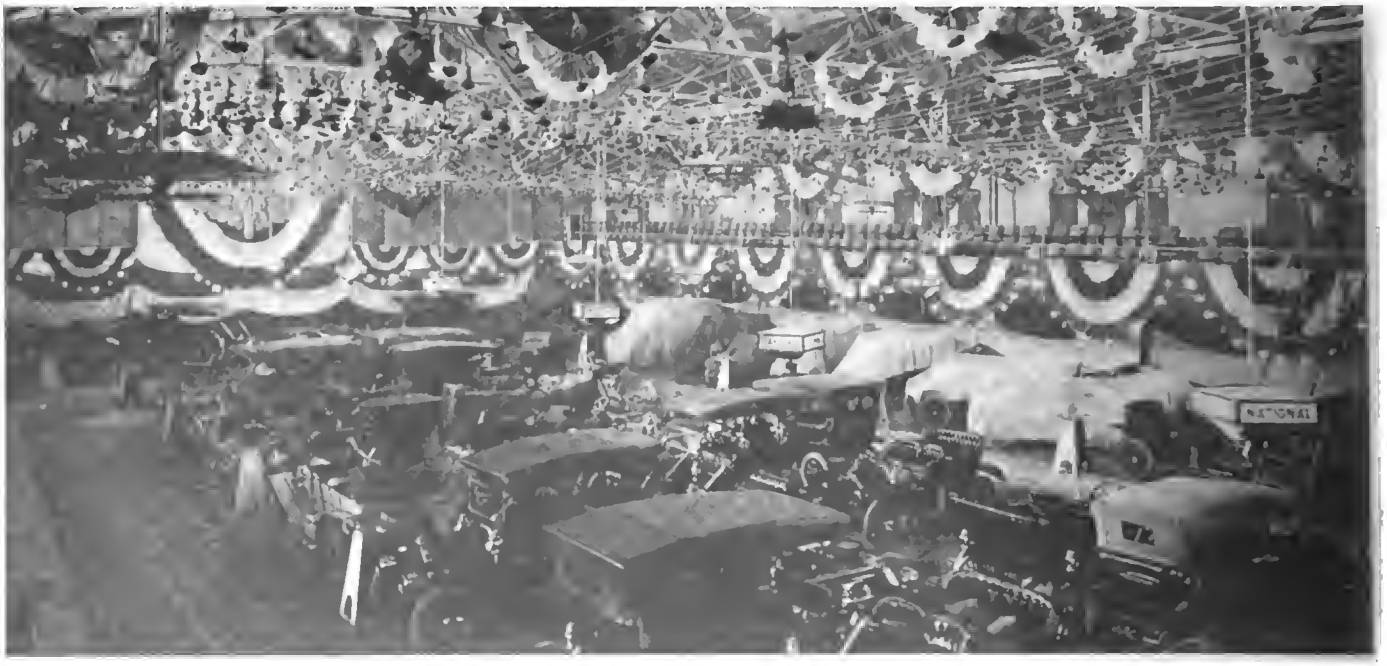
SYRACUSE SHOW REFLECTS EXPERIENCE AND ART

SYRACUSE, Mar. 16—Many of the local automobile enthusiasts, and not a few of the dealers expressed regret at the delay in opening the Syracuse Automobile Show, which is being held in the New York State Armory, the front of which is here pictured, which delay was due to the custom of utilizing the armory for State purposes on Monday nights, which are ordinarily known as drill nights. It is not believed that the Syracuse Automobile Dealers' Association, which is responsible for the high character of the automobile show, will have to lament at the delay, and in some measure, perhaps, the particularly good arrangement, readiness of the exhibitors, and splendid effect, may be traced to the very fact that ample time was available in which to prepare for the proper display of the 47 different makes, and 85 separate models of automobiles which were there arrayed, at the instance of 46 separate exhibitors.

The main floor and the basement are utilized, the former for the larger portion of the completed cars and the latter for the accessories and trucks. The decorations are not so elaborate as some others have been, but they are very pleasing and the building presents a splendid appearance. Here, again, lack of floor spaces has forced many of the dealers to cramp their exhibits and thus make the showing of their cars a difficult proposition.

The beams and rafters of the drill hall are hung in national colors and emblems. Then underneath is a veritable sky of drooping flowers of paper with lights both above and below. From the balconies are hung circles of bunting at the edges of which are myriads of lights. Palms and green flowers and plants round out the decorations nicely. At the center of the very entrance is a huge imitation pearl shell backed up with a wall of green that makes the entrance very attractive.

The revolving Thomas chassis that attracted so much attention at the Madison Square Garden show is also to be seen here and



View of Main Floor, Showing Baker Electric, Oakland, Oldsmobile, National, Ford and Others

Franklin Has a Notable and Very Complete Exhibit in Its Home Town Automobile Show. Torpedo at Right

is one of the drawing cards. In this same breath should also be mentioned the gray Franklin torpedo. This, too, was seen in the Garden and here as there it is almost unapproachable because of the enormous crowds surrounding it.

The Chalmers "Bluebird," winner of the Massapequa, also comes in for its share of attention. Elsie Janis' American Simplex or as it is now known Amplex with her photo gayly poised in one seat comes in for its share of attention among the novel-

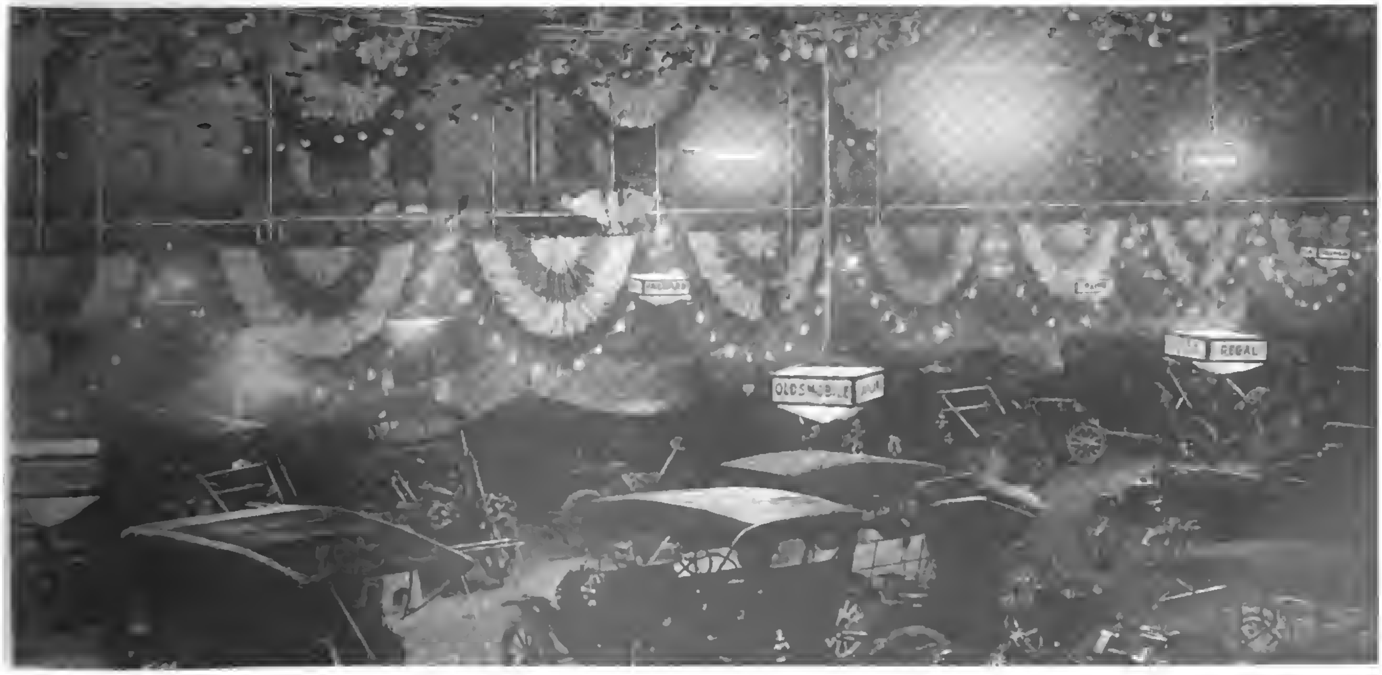
This in addition to opening night is Automobile Club night and the local club members are out in force. A vigorous campaign is being waged this week for members.

Wednesday is Chamber of Commerce day and the business men who compose that august body are expected to attend in a crowd. They seem to realize the value of the exhibit to the community and are dignifying it by their presence.

Thursday is society day with double admission. Friday is turned over for the benefit of the Mystic Krewe. This is a festival organization here corresponding to the Mardi Gras and other festivals of other cities. Saturday will see the University students turned out in force, and a gala time is expected.

The general management of the show has been in the hands of Harry D. Van Brunt and well has he looked after his end of the work. Not one jarring note could be found and the work of a master hand is in evidence on every side.

Billy B. Van, in vaudeville with the Beaumont Sisters, who is playing here this week, pulled off an original stunt on C. Arthur Benjamin, president of the local association. Mr. Benjamin has a Packard Thirty in the lobby of the Yates Hotel on exhibition. While he was at the show this afternoon Van tied on the hood a sign bearing this information: "Presented to Billy B. Van by the Hotel Clerks of Syracuse." 'Tis rumored that one Benjamin has said that he will buy freely.



A Corner of Syracuse Show Where Palmer-Singer, Oldsmobile, Packard, Regal and Baker Electric Held Forth

AMONG THE GARAGES

Reo touring car full of champions. Jeffries at the wheel; front seat, Jack McCormick and Frank Gotch; rear, Berger, Roller and Farmer Burns, all well known in sporting circles

James M. Beaver and Edgar Barber, of Lincoln, Ill., are having erected a garage building, 40 by 90 feet, of brick and concrete, on Logan street. The building will be well equipped with all modern conveniences. The agencies of the Chalmers, Hudson and Haynes cars have been secured.

Findlay, O., is soon to have a garage. Messrs. Johnson and Fortune have formed a partnership for this purpose and are remodeling the Edwards property on North Main street. They will take the agency for some car not yet decided upon and also will do a general garage business.

To accommodate the line of Regal cars, for which he holds the Trenton (N. J.) agency, John H. Ashton has begun the construction of a garage at 227 North Broad street, in that city. The building is to be three stories in height, and will make a handsome home for the Regal.

The Tynan & Reynolds garage, at 173 Van Houten street, Paterson, N. J., which was destroyed by fire recently, is to be rebuilt as soon as possible. M. A. Beekman, the owner of the property, is having plans made for a two-story structure 50 by 100 feet, to cost $3,800.

A garage is being built at 142 North Broad street, Philadelphia, by M. R. Dillin. It is a six-story structure 51 by 83 feet, and the cost will be approximately $80,000. The location is an excellent one, and there is every reason to believe that the venture will be successful.

The Woodsdale Motor Car Company, of Woodsdale, W. Va., a suburb of Wheeling, is now established in its new garage, which includes a well equipped repair shop. The Woodsdale Company has the local agency for the Chalmers and the Hudson.

The Central Garage Company, of Streator, Ill., has opened a garage at 125 South Park street. The building is a modern one of concrete block construction, 53 by 140 feet. The company has the local agency for the Moline.

Plans have been drawn for a garage to be located on the east side of Cleveland street, Orange, N. J., to be 40 by 100 feet. Robert Wright, of that city, is the promoter of the idea.

E. C. Sweet & Son, of Reedsburg, Wis., have opened a garage and repair shop and will distribute the Regal, with the Curtiss motorcycle as a side line.

Brief Personal Mention

Paul L. Snutsel, the well-known Belgian automobile engineer, sailed on the White Star liner *Adriatic* March 12 for an extended trip of six months or more through Europe in the interest of the Splitdorf magneto. Mr. Snutsel will go direct to Turin, Italy, and will have charge of the Splitdorf exhibit at the automobile show to be held there early in April, after which he will visit the different manufacturers of France, Belgium, Germany and England.

Will B. Wreford, well-known sporting writer, and for some years automobile editor of the Detroit *Free Press*, has severed his connections with that paper, and on March 15 will become sales manager of the Michigan selling branch of the Columbia Motor Car Company, handling the gasoline cars made by that concern.

W. C. Orrell, formerly manager of the Detroit branch of the Buick Motor Company, has been made purchasing agent of the complete Buick accessory department for the United States. His former place will be filled by C. C. Starkweather, up to the present time local sales manager.

President Miller of the Mar-Del Mobile Company, Packard agent in Baltimore, Md., gave a dinner to twenty-two employees and several visiting automobilists at the New Howard Hotel. The out-of-town guests were Messrs. Chalfant, Gilbert and Baines, of Detroit, Mich.

William F. Sanger, Milwaukee, Wis., representative for the E-M-F and Flanders and associated with the new Milwaukee branch of the Studebaker Automobile Company, is a Republican candidate for Alderman in the Eighteenth Ward, Milwaukee.

Walter E. Flanders, president of the Everitt-Metzger-Flanders Company, Detroit, Mich.

WITH THE AGENCIES

As is well known, our President is very fond of golf. The picture shows him at the Country Club, Augusta, Ga., in a Rambler 45 about to set out for home after an afternoon's play

One of the best appointed of the Hartford, Conn., salesrooms is that of the Packard Motor Car Company, of New York and Hartford. Previous to opening the local branch the Packard was represented by Brown, Thomson & Company. There is a large salesroom on the ground floor and large double doors render moving cars to the street an easy matter. There is also a large elevator to carry cars to the repair department on the top floor of the building. Charles Embeltin, of New York, is manager of the local branch and the repair end is left to the management of John Mead.

F. E. Avery, the Columbus, O., agent for the Packard, gave a dinner party Saturday evening, February 26, at the Ohio Club in honor of a number of the officials of the Packard company who are making an inspection trip of Packard agencies. In the party were E. P. Chalfont, sales manager; J. J. Ramsey, auditor, and J. F. Baines, manager of the service department. In addition to the above-named gentlemen the attachés of the Avery company were present.

The E-M-F and Flanders lines have been placed with the Sanger Automobile Company, 437 Milwaukee street, Milwaukee, Wis. The salesrooms are the same as used by the Milwaukee branch of the Studebaker Automobile Company, of which William F. Sanger, owner of the Sanger concern, is sales manager.

J. D. Maxwell, the creator of Maxwell cars and factory head of the Maxwell-Briscoe Company

Callahan, Atkinson & Company, Locomobile representatives, have opened up new spacious salesrooms and offices in the heart of Baltimore's retail district, at 328 North Charles street. The firm has two carloads of Locomobiles of various designs on display and these attract the attention of many passers-by.

Frank Brosn, Jr., son of Baltimore's former millionaire Governor, has joined the sales force of the Shaab Auto Company. This firm has recently taken on agencies for the Rainer, Marmon, Courier and Billy Four cars, which they handle in connection with the Renault and Stoddard-Dayton cars.

The Washington Automobile Company has opened up for business at 67 East Maiden street, Washington, Pa. D. A. Swart is proprietor of the establishment, which will handle the Lozier, Locomobile, Oldsmobile, Chalmers, Pullman, Cadillac, Overland and Hudson cars.

The Roe-Halverson Auto Company has been organized at Stoughton, Wis., to handle the Overland in Dane county, which contains Madison, the State capital. The partners are Carl and Gustav Roe and S. M. Halverson. They will also distribute the Marion in this territory.

The Taylor Motor Distributing Company has been formed by William T. Taylor, of Philadelphia, and Frank B. Cook and Philip N. Price, of Johnstown, Pa. It will establish an agency in the Real Estate Trust Building, in the latter city, for the Warren-Detroit cars.

William Beitz, of Lomira, Wis., has received the agency for the Black-Crow for Dodge and part of Fond du Lac counties. Dr. J. E. McCarty, of Eden, Wis., will handle the Black-Crow in eighteen counties in Central Wisconsin.

M. S. Keyes, formerly with the Maxwell-Briscoe Company, at the Tarrytown plant, has taken on the Regal agency for the territory in southeastern New York, exclusive of New York City, also Connecticut, Rhode Island, and northern New Jersey.

The Empire Tire Company has opened a branch house in Kansas City, Mo., in charge of Claude Beardsley, formerly a traveling salesman for that company.

The agency for the Clark cars for Kansas and western Missouri has been placed with H. B. Weils, operating as the Clark Motor Car Company, of Kansas City.

The Franklin Cycle & Supply Company, East Gay street, Columbus, Ohio, has taken the central Ohio agency for the Detroit-Dearborn line.

Leslie C. Dorland has secured the exclusive agency for the Demot in Dutchess County, New York, with headquarters at Poughkeepsie.

The Corbin agency for Wisconsin has been placed with the Curtis Automobile Company, of Milwaukee, Wis., State agents for the Reo.

REALM OF THE MAKERS

One of the new model Inter-State cars, in front of the factory at Muncie, Ind. This is the very latest idea in torpedo bodies

"First in the Western Hemisphere," the Aeronautic Supply Company, 3923 Olive street, St. Louis, has issued a catalogue of aeronautic materials and supplies similar to those of the big automobile supply houses. The company's line is very comprehensive, including Gnome, Curtiss, Holmes, Easton and Elbridge motors, Honeywell balloons and dirigible envelopes, Chauvière propellors, Hartford aeroplane tires, Livingston radiators, Warner anemometers, and various kinds of fabric, steel tubing, wheels, wire, turnbuckles, etc. In addition a number of books dealing with aeronautics are listed. Considering the newness of the business, this catalogue reflects great credit on the firm issuing it.

Parry 32-36 horsepower touring cars made good showing on two of the steepest hills of Baltimore recently. In the first test one of these cars made the ascent of the incline, which has a rise of 25 feet in 230 feet, at a speed of 15 miles an hour. J. M. Wright, president of the General Auto Company, local Parry agent, and F. C. Kitchin and G. J. Kessler, of the firm, and Harry Mayer, of the Auto Supply Company, were the passengers. In another test on a similar grade the car, which was driven by Mr. Wright, made the climb at a 20 miles an hour rate. The hills are paved with rough cobblestones.

It is said that the American Motor Car Company of Indianapolis, Ind., has announced that it will leave that city, and from current reports it is said that the Parry Automobile Company has also under consideration proposals to locate in some other city. Some surprise has also been expressed that the American Motor Car Company should move to Lafayette. This latter concern expects to make the change about June 1st, when it will begin on its 1911 line. Citizens of Lafayette have raised $150,000 for the company, $125,000 of which will be used as a bonus for purchasing ground and erecting and equipping factory buildings. The remaining $25,000 is to defray moving expenses.

Coker F. Clarkson, assistant general manager of the A. L. A. M.

The Hewitt Motor Car Company passed from existence Monday, becoming a part of the Metzger Motor Car Company, of Detroit, whose capital has been increased to $1,000,000. Although its corporate existence has been terminated, the Hewitt plant in New York will be operated until a Detroit factory can be erected, which will probably be about midsummer. Twenty acres of ground will be used as a site for the motor truck plant, which will be conducted entirely independent from that at which Everitt pleasure cars are now made, and some $250,000 will be invested in buildings and equipment.

One of the interesting features of the Milwaukee automobile show was a train run by the Kissel Motor Car Company from Hartford to Milwaukee during the show week. All the employees of the Kissel Motor Car Company were invited to the show at the expense of the company and, in order to make the trip conveniently, without interfering with working hours, a special train was chartered by the Kissel company itself, which hauled a large trainload of employees from Hartford to Milwaukee and back again, giving them opportunity to spend Sunday at the show.

Flint, Mich., is to receive a further boom as the result of two more important plants having been taken over by the General Motors Company and moved to that city. These are the Randolph Motor Car Company, of Chicago, and the MacClean Wheel Company, of Cleveland. The former company manufactures a motor truck, and will employ some 400 men. The latter makes a spring wheel of new type, which will be used on all motor trucks produced by the associated General Motors plants throughout the country, it is stated.

The keels (chassis) for the Moline "Dreadnought" squadron which has been entered for the 1910 Glidden run have been laid and work started in preparing this unique trio for the year's most popular endurance run. They will be put through some strenuous work among the hills in and around Moline before taking on the official war paint, which will be battleship gray, as of last year. The record achieved by the Moline in the 1909 run is evidence that it will be a prominent contestant in 1910.

The Clark Motor Car Company, Shelbyville, Ind., is now well under way, with cars coming through in quantities, and is making daily shipments.

Great Smith is now numbered among the ranks of the makers licensed under the Selden patent.

NEWS IN GENERAL

At the Boston show the White Company showed the practicability of the three-ton truck by using it to carry all material to the show

Eight prizes will be offered to automobilists who tour to Fort Worth, Tex., to attend the automobile show which will be held there March 14-19. Perhaps the most novel offer is that of E. O. Thackston and Tom Massey, of the Overland company, namely, a speedometer for the first out-of-town car which breaks the speed limit during the week. Other prizes are *Star-Telegram* trophy to the west Texas town or city sending in the greatest number of cars; Troy wind shield, by the Moline company, of Dallas, to the car which comes the greatest distance to the show; cup by the Maxwell-Briscoe-Handley Company to the group of cars which show the greatest combined mileage; silver cup, by the Texas Motor Sales Company, to the West Texas autoist bringing in the greatest number of ladies in his car; horn, by F. F. Simons, of the Stevens-Duryea Company, to the autoist bringing the greatest number of children in his car; speedometer to the first car, coming at least fifty miles, and reporting at the office of the Fort Worth *Live Stock Reporter;* eight-day clock, by the Buick company, to the car which has been in service the longest.

Increasing the size of the contest board of the Chicago Automobile Club from three to eight members would seem to indicate that President Ira M. Cobe is planning a vigorous campaign, although up to this time he has given out nothing official for publication. Joseph F. Gunther has been retained as chairman of the committee and his two 1909 associates, A. J. Banta and C. G. Sinsabaugh, also have been appointed. But President Cobe has added five others to the list, three of whom come from the trade—James E. Plew of the White, A. M. Robbins of the Oakland and Thomas J. Hay of the Ford. H. N. Scott and W. H. Thompson make up the rest of the committee.

At a special meeting of the Boston Automobile Dealers' Association, held last week, the matter of motor legislation was discussed. President L. R. Speare of the American Automobile Association was present and went over some of the bills presented. The various measures selected were discussed by the members who endorsed them, but owing to the rush incident to getting ready for the motor show they were not able to appear before the legislative committee. James T. Sullivan was appointed as representative of the association to outline their view at the hearing of the bills.

Local dealers in Baltimore have come out flatly with the statement that they and not the Automobile Club of Maryland will run shows here in the future. Club members, on the other hand, through Assistant Secretary Hutchison, assert that they have no intention at this time of discontinuing the idea of being the moving spirit in any shows to be held in Baltimore. The result is that if both sides stick to their declaration Baltimore is likely to offer two shows to the local public.

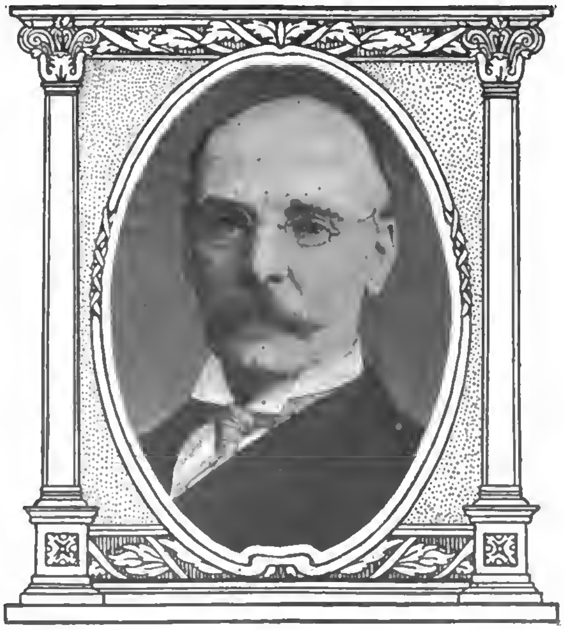
The Venango (Pa.) Automobile Company, composed of C. E. Trace and Charles H. Sheasley, and the Myers Carriage Company, have been sold to the Franklin Commercial Truck Company, which will manufacture, buy and sell automobiles. The main interest in the two old companies will control the new concern, which will be in Franklin, Pa., and will have its plants at Thirteenth and Buffalo streets in the same city. The capital is $100,000.

The American Taxicab Company is a new Pittsburg concern located at 307 Arrott Building. The officers are: President, George J. McGinty; vice-president, James N. McGinty, and secretary and treasurer, A. A. Firestone. The company is already operating several taxicabs and will soon add a large number and establish substations in different parts of Pittsburg. This is the third taxicab company now operating in that city.

Washington, D. C., has been added to the list of cities where Alco taxicab service now exists. The Auto Livery Company has placed an initial order for a lot of cabs; the first shipment has been made. This company plans eventually to replace all of its old stock with the same type of Alco cabs now in service in New York, Philadelphia and a number of other large cities.

Six automobile shows were held during February in the Middle West and Far West, these being Los Angeles, Salt Lake City, Denver, Kansas City, Minneapolis and Omaha.

The tent erected for the Los Angeles automobile show is the largest ever raised in America. It covers 40,000 square feet.



Thomas Henderson, vice-president of the Winton Co., Cleveland

REGARDING REISSUES OF AUTOMOBILE PATENTS

By XENOPHON P. HUDDY, LL.B.

AMONG the various branches of the law in which we find the automobile and its operation the subject of legal controversies, the Law of Patents, so called, is the one branch of our jurisprudence that is at the very foundation, basis and life of the automobile industry. Independently of statutory enactment and under the common law an inventor possesses no right to restrain others from using his invention, but in order that the public may enjoy the benefit of an invention, the State grants to the inventor the exclusive right to make, use and vend the invention for a limited period, provided that the originator furnishes a full, clear and exact description of his invention so that after the patent has expired, the article may be manufactured generally for the benefit of the public.

DEFINITION AND NATURE OF PATENT

So it may be said that a patent is a grant by the government to the inventor of the exclusive right to control the manufacture and use of the article for a definite time. It has the essentials of a contract. Of course, the law governing automobile patents is not different from the law controlling other inventions. We will now direct our attention to reissues of patents.

REISSUES OF PATENTS

A patent being originally granted to secure certain rights to inventors for a limited time, a reissued patent is one which secures those rights more definitely in some particular wherein the original patent was defective. A reissued patent is in the nature of an amendment of the original. There are limitations, however, on the right to secure a reissue.

LAW GOVERNING REISSUES

The Revised Statutes of the United States, Sec. 4916, provide for the reissue of defective patents as follows:

"Whenever any patent is inoperative or invalid, by reason of a defective or insufficient specification, or by reason of the patentee claiming as his own invention or discovery more than he had a right to claim as new, if the error has arisen by inadvertance, accident or mistake, and without any fraudulent or deceptive intention, the Commissioner shall, on the surrender of such a patent and the payment of the duty required by law, cause a new patent for the same invention, and in accordance with the corrected specification, to be issued to the patentee."

SEVERAL PATENTS FOR SEPARATE PARTS

There are other provisions of the statute authorizing the Commissioner to cause several patents to be issued for distinct and separate parts of the invention patented, upon request of the applicant and payment of the fee for a reissue for each reissued letter. The specifications and claims in every such case are subject to revision and restriction in the same manner as are original specifications.

INTRODUCTION OF NEW MATTER

No new matter, however, can be introduced into the specification, nor in the case of a machine patent can the model drawing be amended, except each by the other, but when there is neither model nor drawing, amendments may be made upon proof satisfactory to the Commissioner that the new matter or amendment was a part of the original invention, and was omitted from the specification by inadvertence, accident, or mistake.

STATUTORY PROVISIONS LIBERALLY CONSTRUED

The provisions of the statute governing reissues are to be construed liberally, but the mistake or accident before referred to must have been *bona fide* and not purely an error of judgment, and it is held that the patent must have been inoperative and invalid.

WHEN REISSUES WILL BE GRANTED

Prompt action should be taken by one who desires a reissue, since laches and unreasonable delay may defeat the right. A reissue obtained after unreasonable delay and for the purpose of expanding the patent claims to embrace devices appearing since the issuance of the original patent and which are not infringements, has been held to be void. In some cases a delay of two years has been held to be unreasonable. If, however, there exists a reasonable and lawful excuse for the delay in making the application for a reissue, the application will be recognized For instance, where a patent was obtained June 6, 1882, and was held to be void by the United States Circuit Court, June 19, 1894, and by the Circuit Court of Appeals, October 22, 1894, a reissue dated March 11, 1895, was held not to be void by reason of lapse of time, in Maitland B. B. Goetz Mfg. Co., 86 Fed. Rep. 124.

WHAT MAY BE CLAIMED

Generally speaking the reissue must call for the same invention and no new matter can be included. A broader claim may, however, be made if it is for the same thing. New features may also be included. In other words, all that could have been claimed originally may be requested in the reissue. But if letters patent fully and clearly describe and claim a specific invention, complete in itself, so as not to be inoperative or invalid by reason of a defective or an insufficient specification, a reissue cannot be had for the purpose of expanding and generalizing the claim in order to embrace an invention not specified in the original. So also letters patent for a machine cannot be reissued for the purpose of claiming the process of operating that class of machines; because, if the claim for the process is anything more than for the use of the particular machine patented, it is for a different invention. See James vs. Campbell, 104 U. S. 356; Burr vs. Duryee, 1 Wall, 531; Powder Co. vs. Powder Works, 98 U. S. 126.

TERMS OF REISSUE

A reissued patent is valid only for the remainder of the term of the original patent.

MODIFICATIONS OF BELGIAN PATENT LAWS

Consul H. Albert Johnson, of Liege, reports that a national association has been organized to study industrial proprietorship, reforms and modifications of Belgian laws concerning patent rights and trademarks and international agreements relating thereto. He says:

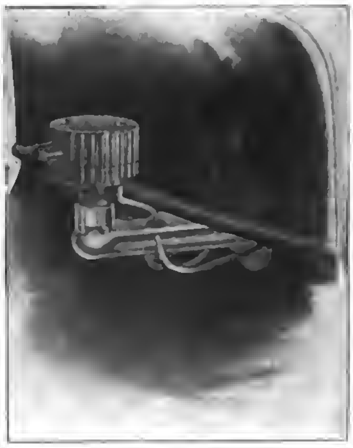
The National Belgian Society for the Protection of Industrial Proprietary Rights has been organized, with the co-operation of the Director-General of the Department of "Industrie et du Travail," the Director of the "Office des Brevêts" (patent office), a number of the leading legal specialists, and prominent industrial concerns. The Belgian patent laws now in force date from 1854; those controlling trade-marks from 1879. So far as the submission of models and drawings is concerned, procedure is regulated under the decree promulgated during the time of Napoleon I, dated March 1, 1806.

It appears that under the method of procedure at present in force, in the case of an application for a patent, no provision is made either for a preliminary examination of existing patents or for printing a description of the patent issued. As these matters are considered of prime importance, the association proposes to direct its efforts toward the enactment of legislative action that will result in providing as speedily as possible for such an examination and for the printing of the description of the patent. Another important point to be urged by the new association is that of arranging the Belgian patent laws in conformity with the rulings of the international convention.

It is also claimed that there are various matters regarding the routine work incidental to procuring a patent in Belgium that can be greatly simplified in the interests of inventors, and it is asserted that, out of consideration for the many important industries in Belgium, all legislation concerning industrial proprietary rights should be given new life and be placed on a thoroughly up-to-date basis.

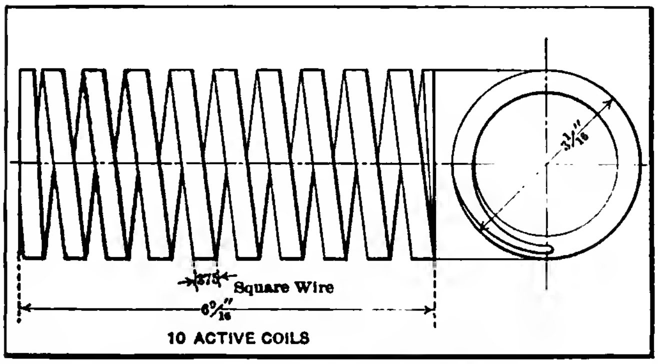
PROMINENT ACCESSORIES

HART & FULLER, of Hartford, Conn., have brought out a device for electrically lighting acetylene lamps which operate on the ignition circuit. The advantages of the device are that it requires no separate source of current and no individual spark coil; these economies are reflected in the consequently low price. In fact, the only parts of the device are a switch, the gas-tank valve, the "spark plugs," the points of which project across the jets of the acetylene burners, and the wiring. The switch is conveniently located under the overhang of the front seat, so that it is practically invisible and at the same time is easily reached by the operator.



Hart Gas Lamp Lighter

This switch is so connected into one of the high-tension circuits that the latter can be short-circuited across the lamp spark plugs. These have their points rather closer together than the cylinder spark-plugs, and do not work under compression, so that this circuit offers considerably less resistance than the regular one, and the current flows through it by preference whenever the switch allows. The valve of the gas-tank is disposed by the side of the switch, convenient to the operator's hand; the gas is first turned on, and after a suitable interval, to allow it to reach the burners, the switch is turned on and the spark jumping across the jets ignites the gas. This system offers the excellent advantage of permitting the autoist to control the intensity of illumination from the lamps by the mere process of adjusting the flow of the gas by the means which is ready at hand.



Square Wire Clutch Spring Used on Alden-Sampson Trucks

Among the interesting features of the Alden Sampson trucks, made by the Alden Sampson Mfg. Co., of Pittsfield, Mass., is the clutch spring, an illustration of which is offered herewith. The spring, contrary to the usual practice, is formed of square instead of round wire, the cross-section being 3-8 inch in each dimension. The spring is wound on a special machine, and the ends are ground off at right angles to the axis. There are ten complete coils. The overall dimensions are 6 9-16 inches long and 3 1-16 inches in diameter.

PARKER AUTOMOBILE TRANSMISSION GEAR

CHICOPEE FALLS, MASS., is the scene of a new undertaking which is attracting the notice of automobile engineers of discrimination. The Parker transmission gear, a section of which is here given, is responsible for the excitement, and it promises to overcome the mechanical objections to the clash type of sliding gear now in common use in automobiles. The Parker gear, as the section shows, is of the type which allows the sets to remain in constant mesh, but by means of sliding members which are flush in grooves of the respective shafts. The speed changing gears may be selected to suit the exigencies of service, and the remaining gears are idle. The system has been tried out under severe conditions of service, and the new design will economize space considerably, as compared with the first model, as here illustrated. In this case, the multiple disc clutch is within the gear housing, but this is a detail which may be altered at will. The same thing, of course, applies to shaft centers and other details.

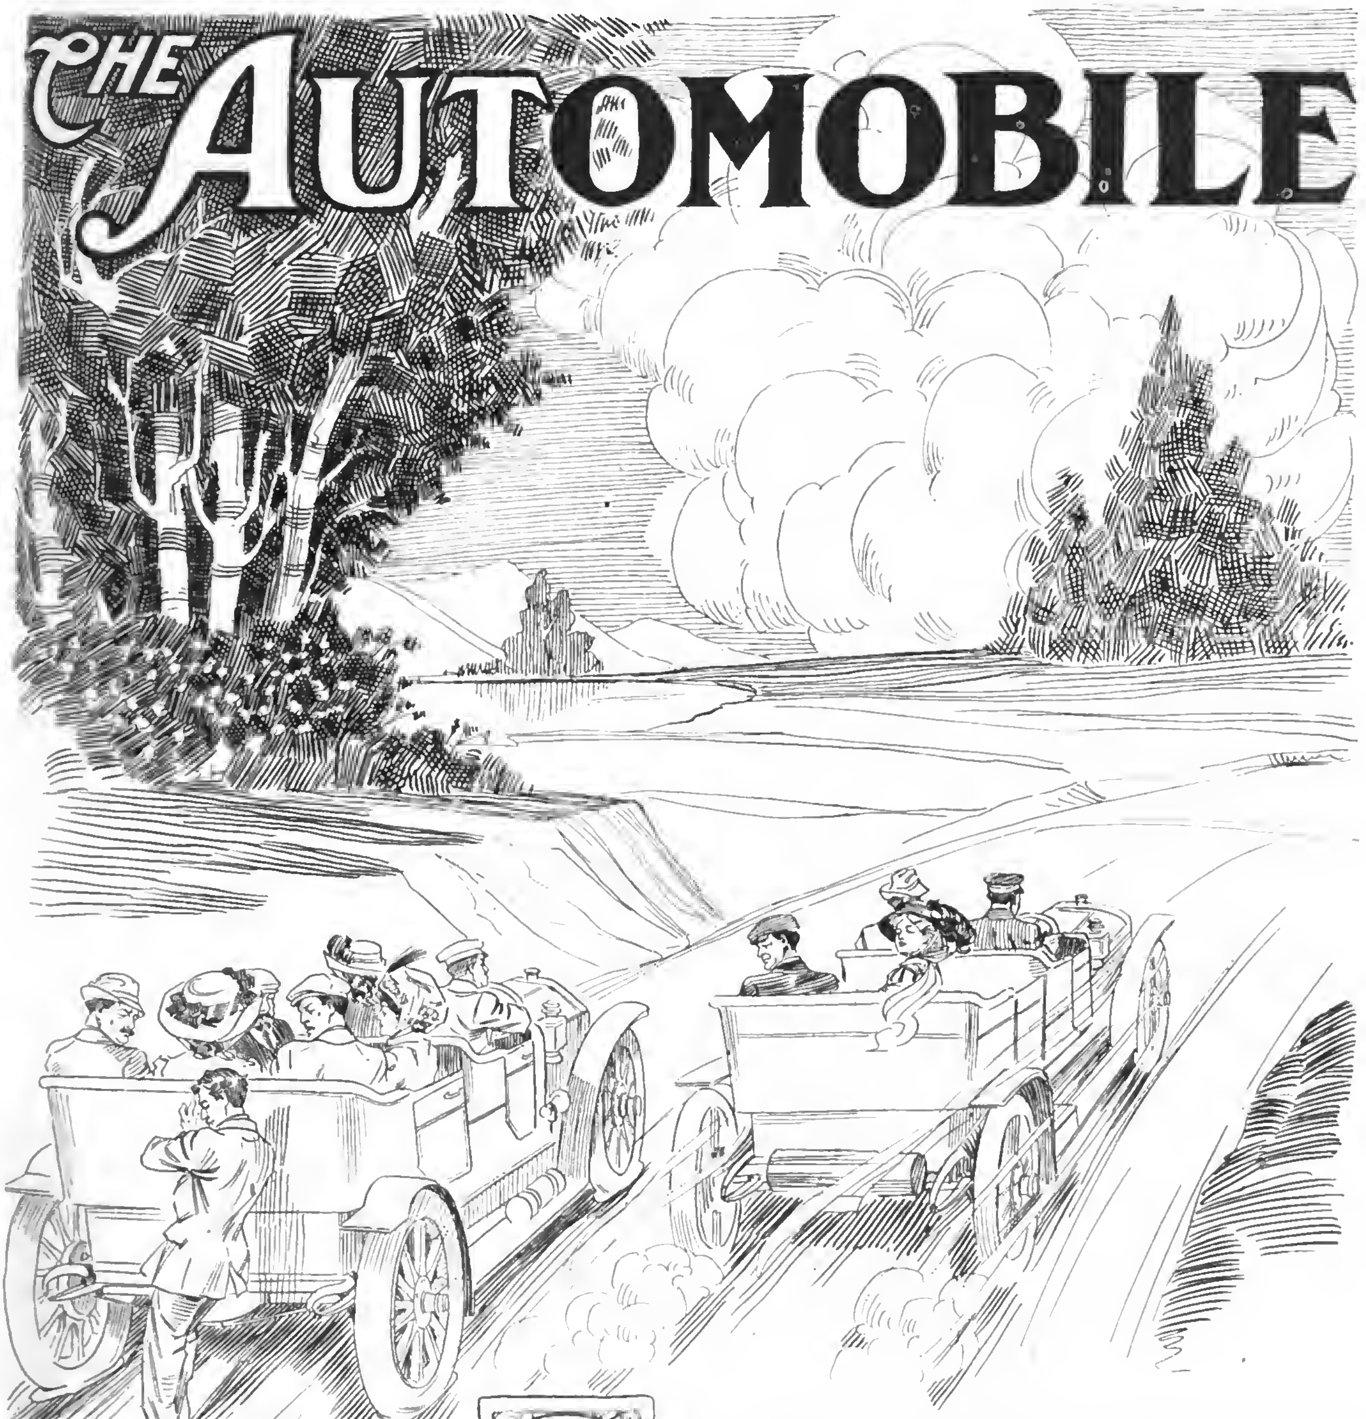
INDEX TO ADVERTISERS

Vol. XXII New York—Thursday, March 24, 1910—Chicago No. 12



SPRINGTIME offers its lures, and the budding autoist with his recent purchase will find himself within the zone of a double attraction, and he is to be congratulated when the air becomes balmy, the roads dry up and the sweet running automobile, fresh from the maker, offers him every facility with which to enjoy life. If it is the first car and it will be for better than a hundred thousand recruits to the ranks to the users of automobiles this year, each one of them in contemplation of the pleasurable advantages to be derived will have to consider the responsibilities as well, and, if the advantages are not to be dimmed by adverse incidents, certain important requirements will have to be given the attention they deserve.

All men are not, by right of birth, mechanics; some men cannot even acquire a reasonable degree of mechanical proficiency, and even those who can, unless they practice daily in the mechanical arts, overlook the important considerations, allowing their training to fall into disuse, and take pattern after the environment in which they live, so that when they acquire their first automobile they accept it as a mere substitute for a horse, excepting that they give it credit for a wider range of activity, and assume that it will withstand abuse almost without limit, hoping, perchance, that steel has life everlasting. The trusty horse has something of an advantage over an automobile, due to his ability to lay down when he is tired, but the automobile must go on and on until it pulls asunder, and in the process presents the only evidence of abuse that is acceptable to the non-mechanical mind. In the case of the horse, it is very rarely that the loading is so excessive as to stall the animal; humane considerations have their wide and useful influence, but it is very rarely that the human attribute influences for good when an automobile is taken into account.

METAL MUST BE TREATED IN CONFORMITY WITH LIMITED LIFE

The first point to consider when an automobile is being placed in commission must be that the life of the material is positively limited, and that it will be prolonged in proportion to the care with which it is handled. Metallurgists, while they fail to give definite reasons in many of their statements in relation to the life of structural material in actual use, quite generally agree with each other, to the effect that strains, shock and especially alternate vibrations tend to shorten the useful life of the material, and this tendency becomes very marked indeed when the material is overworked.

This is by no means a place in which to indulge in a technical discussion of the vibratory value of steel and other structural materials which are in common use in automobiles, but there are two or three plain truths which the new autoist can afford to take under advisement until experience will come to his assistance and enable him to think rationally for himself. In order to properly understand this situation, it is necessary to go back into the history of the automobile to the time when the designs were so crude that the weight of the cars was in considerable excess of that which could be tolerated. Designers, in view of this consideration, exerted themselves to the utmost to reduce the weight of the component parts in order that the weight of the cars as a whole would come within the requirement.

Reducing weight, while it was an evolutionary process, involving four or five years of persistent effort, demanded two things, *i. e.,* (a) the utilization of dynamic material, (b) the careful working out of the proportions of the parts in order that the extreme fiber strain would be within practicable limits. Engineers are very fond of quoting what they call a dictum, "a chain will be as strong as its weakest link." This dictum sounds as if it were the very essence of wisdom, but a chain is by no means an automobile, and while it is a relative simple process to make all the links nearly of the same strength in a chain, it is extremely difficult to make all the members of an automobile so harmonious in their several relations that they will each of them serve under precisely similar conditions.

There are a thousand reasons why designers are not yet prepared to assure equality of work of the several parts in the make-up of a car, although the situation at the present time is almost up to the point where standardization may become a reality. In the meantime when the new automobile is put into commission, it will be well to remember that legitimate expectation is positively limited to the loading of the car within the limits as fixed by the number of seats available as it comes from the maker. Any extra weight which is placed as a burden upon any automobile is bound to react against the owner, and it is sure to add to the cost of maintenance besides reducing the useful life of the car.

A CAPABLE KIT OF TOOLS SHOULD BE CARRIED ALONG

In discouraging the undue addition of burden to a car, it should not be understood that a reform will be wise, if it results in the undue limiting of the tools which an autoist should have available. It makes no difference who builds an automobile, of what material it is made, or how good a design, it is subject to all the fundamental laws, and its parts are likely to become deranged under road conditions, so that good tools are of the greatest importance and, unfortunately, the conditions under which they are usually required are those which do not permit of falling back upon a repair shop. Even if repair shops were so closely spaced as to permit one to rely upon them entirely, the fact remains that it is an expensive experiment to call for help at the nearest repair shop, under such conditions. It is reasonable practice to trust the repair man whose capabilities are established and known to the owner of a car, but it is not safe to call for help, in a remote district, from a repair man who does not feel the responsibility of doing work for a regular customer.

A roadside repair is best made by the owner of the car, and in order to be able to do so it is necessary to have in hand, for ready use, a wise selection of capable tools. In the selection of tools, account must be taken of the market conditions in which it seems that there is a wider variety, from the point of view of quality, in the hardware line, than there is in any other class of trade. To the inexperienced autoist, for illustration, all files look alike, but the experienced mechanic is perfectly aware of the great differences which exists between them. At all events, the autoist, as he must face a breakdown on the road, is compelled to regard a file as his substitute for a lathe, shaper, planer, grinder and all the other machine tools which are at the disposal of the builder of the car.

If a file becomes of such extraordinary importance, and it surely does, considering the fact that one good file will outlast a thousand bad ones, it is a mere illustration of the same condition as it obtains in connection with all the tools which should be carried along. Emphasizing the necessity of having available a competent tool kit is by no means licensing a burdensome excess. Tools are difficult to store, and when they are in excess they defeat prompt work, because the useless devices invariably get in the way, and the trouble involved in finding the right ones is accentuated. A self-contained condition of autoing, considering a car which starts out in good working order, should be a reasonable expectation, were a kit of tools to be made up as substantially set forth elsewhere in this article.

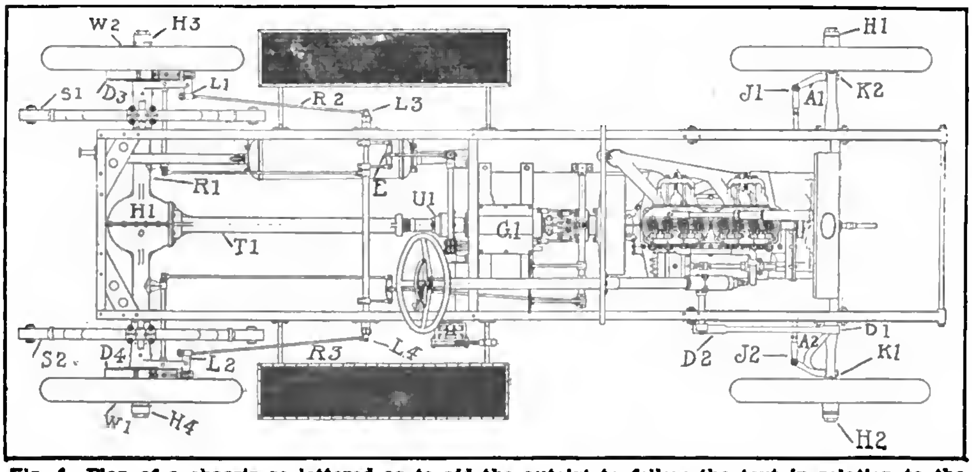


Fig. 1—Plan of a chassis so lettered as to aid the autoist to follow the text in relation to the putting in commission of a new automobile.

CLOSE INSPECTION IS DESIRABLE

A new automobile is supposed to be in good working order; it even offers evidence of this necessary qualification when it is delivered to the owner's garage under its own power, or when it responds to a sufficient demonstration to warrant its owner in making the purchase. Even under the most favorable conditions it is wise, especially for a new autoist, to expend quite a little of his time in going over the mechanism in detail, partially for the purpose of becoming familiar with the construction, and finally with a view to ascertaining if all the units are properly related to each other, and if the bolts are fetched up with their heads against the bosses, the nuts in tight relation and the cotter pins in place.

Fig. 1 presents the outline of a chassis, and will be utilized in a further discussion of this part of the subject for the purpose of aiding the reader. Beginning at the front of the car, the knuckles K1 and K2 should be examined to see if there is lost motion, and by jacking up the front axle, it will then be easy to find out whether or not the joints are too tight, and it must be remembered that there is just as much chance of future trouble in a joint that is too tight as there is in one when it is slack. While the front knuckles are receiving the attention they deserve, it is an excellent time to back off the hub caps H1 and H2, then remove the knuckle spindle nuts, take the wheels off and carefully inspect the front wheel bearings. If the grease looks offcolor, it will be an excellent idea to clean the bearings and the cavities of the hubs, using a scraper in so far as it becomes necessay, and kerosene oil for the most part. At all events, it is well worth while making sure that the bearings are with a little "shake," which means that they should respond to pressure and show that they are not bound, and they should be scrupulously clean and then reassembled, after which the wheels can be returned to the spindles, the hub nuts screwed on, cotter pins put back, and the last operation should be to pack the bearings with a suitable grade of grease and screw the hub caps H1 and H2 tightly into place.

It would be regarded as a careless undertaking, were an autoist to consider the front axle inspection completed without examining the steering arms A1 and A2, the joints J1 and J2 and the drag rod connections D1 and D2. These joints should be dissembled, cleaned out most thoroughly, and after reassembling they should be packed with a suitable grade of lubricating grease. Many of the better grades of automobile makers boot these joints in order to protect them against the silt of the road, and also to keep them in a state of copious lubrication, which is due to the means afforded to keep the grease in.

LIVE REAR AXLE OFFERS EXTRA OPPORTUNITY

The front axle should be given attention on account of its relation to steering, and the hazard which comes if the steering functions are not on a substantial basis. The rear axle is of equal importanc,e since, if it becomes deranged, power may not be transmitted to the point of contact of the tires with the road. It is the front axle then, which must be examined on the ground of safety, and the rear axle, for the reason that it is a power transmitting device. Referring again to Fig. 1, the rear axle R1 takes its power from a shaft which connects between the transmission gear G1 and the bevel drive, which is in the housing H1 of the axle. The shaft is enclosed in a torsion tube T1, and a universal joint U1 takes care of the relative moton between the axle and the chassis. The wheels W1 and W2 are in rigid relation with the jackshafts which connect with the bevel drive through the differential, all of which members are enclosed in the axle tube, with its central enlargement H1. It is not believed that a new autoist should be so venturesome as to attempt to dissemble this aggregation of extremely important transmission members, but he should understand that all the covers should be screwed down tight after the parts to whatever extent they are get-at-able through handholes are inspected, rendered perfectly clean and properly packed in a suitable lubricant. The hub cap H3 and H4 should be screwed into place last, and a very good way to make sure that lubrication will be profuse is to fill the caps with grease before screwing them into place.

BRAKES SHOULD BE ADJUSTED WITH DISCRIMINATING CARE

There are several problems in connection with brakes which have to be coped with almost independent of the design of an automobile. The rods R2 and R3 are diagonally placed in their relation between the lever L1 and L2 and the cross-rod levers L3 and L4. The result is that the tightness of the brakes will be variable depending upon the extent of loading of the body as it varies the compression of the rear springs S1 and S2. It is for this reason that an overloaded car, when it is going down a grade, is likely to have its brakes deranged, and accidents are thereby courted.

The extent to which the brakes are likely to become deranged as a result of excess loading will depend upon the length of the rods and the angularity. The length is intended to be sufficient for automobiles that are not overloaded, but the angularity will increase with overloading, and experienced autoists take into account the variable which is present and make brake adjustments accordingly. In some automobiles it is necessary to so adjust the brakes that they will press slightly against the drum faces when the load is light, in order that the brakes will work when the load is normal.

When the brakes are applied, the pressure to the two sides is equalized through the use of an equalizer E, but the adjustment must be so nicely made that the equalizer will be free to act. Unless pressure is applied equally to the drums D3 and D4, the brakes will fail to perform their function satisfactorily, and the tires will be subjected to undue strains. The ability of any set of brakes is limited to the tractive ability of the tires in contact with the roads, and if the equalizers fail to work, and the braking effort is thrown entirely to one road wheel, skidding is induced and the results are but little better than if no brakes are used. The maximum brake effect is always present when the shoes press on both sets of drums uniformly, and just to the point which approaches the maximum adhesion. The instant adhesion is overcome, the ability of the brakes falls off to a nominal point.

THERE IS A PROBLEM RESIDING IN THE TIRES

It is inexpedient to discuss brake adjustments without taking up the tire problem, and it is the new autoist who fails to appreciate the true situation. A car will respond most willingly to the pressure of the brakes if the same is applied skillfully and without undue haste. It takes four measures of power to

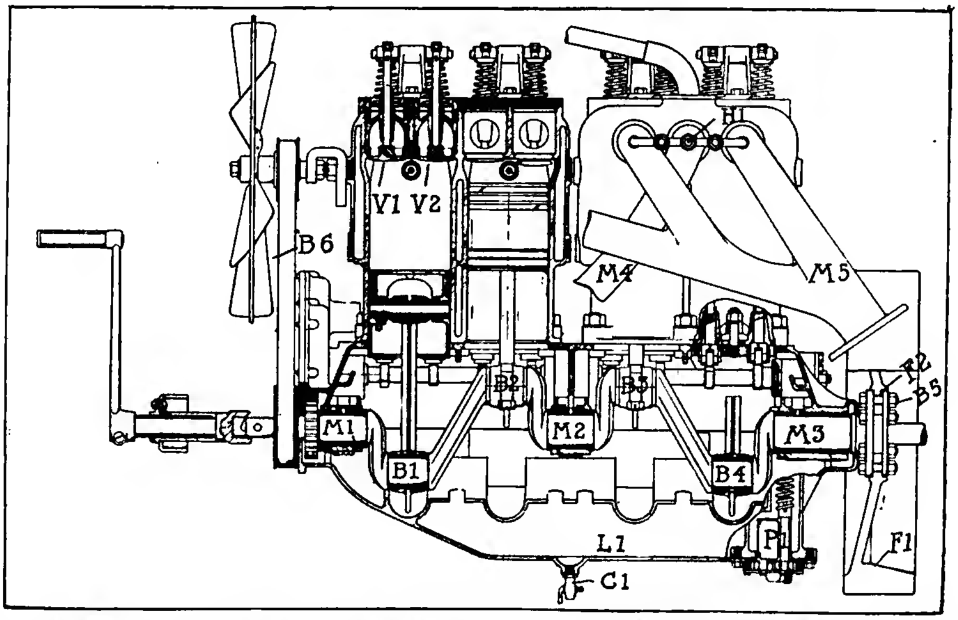

Fig. 2—Section of a 4-cylinder motor so lettered as to help explain the text in relation to the inspection of a new motor before extended use

accelerate the speed of a car to double a given value in a given time, and this statement when inverted may be rearranged as follows: It puts four times as much work upon the tires if the motion of a car is arrested within half of the given distance. This will be true if the wheels are not induced to skid, but after skidding begins the damage which may be done to tires must be confined to the realm of speculation. The tire situation, in view of what has been said, will be less of a problem if the brakes are applied with deliberation and soon enough to permit the car to be brought to rest without the expenditure of a great effort.

There are very few autoists who are able to get away from the idea that tires may be inflated to excess by means of a hand pump. It is quite impossible to inflate any set of tires such as are used on automobiles to a point where the pressure will be greater than that which the fabric should be capable of retaining. The life of tires is enormously reduced when they are flexed repeatedly under load as they invariably will be if the air pressure is insufficient. The one rule which, if observed, will make the most marked saving in cost of maintenance, is that involving the inflation of tires to a point considerably beyond the present average practice.

Tire life is much shortened if the tire on one side is inflated differently from that of the other. The wheels will not then cover the same distance over the ground per revolution, and as a result they tend to roll around in a circle, but since they are restrained from doing so they drag. It is this continued and useless effort which is expended at the point of contact of the treads of tires with the road bed that is at the foundation of much of the tire depreciation which is experienced.

The safe rule is to inflate all the tires equally, and to employ a gauge in order that the pressure may be observed with certainty. It is not possible for any man to decide in the absence of a gauge the extent of pressure in a tire. If the tires are inflated sufficiently, they will cease to do the work which properly belongs to the springs, and if the springs are stiff or improperly designed, the performance of the car on which they are used will be unsatisfactory at high speeds, even on a good road. Under such conditions it will still be good practice to inflate the tires sufficiently to protect them against flexure, and the remedy to take advantage of in order to limit undue vibration lies in limiting the speed of the automobile on the road to the point which will eliminate evidences of excess vibration. At all events, referring to Fig. 3, A represents a side view of a tire when it is properly inflated, B is an end view of the same tire, C is a side view of the tire when it is not properly inflated and D represents the same tire looking at it from the other plane. These views, which were furnished by the Diamond Rubber Company, indicate very clearly what tire makers have in view from the point of view of insufficient inflation of tires, and, as they point out, it is impossible to expect good result if the fabric is flexed as it will be if the tires are not fully inflated.

SOME FURTHER MOTOR CONSIDERATIONS

Referring to Fig. 2 of a motor in part section, F1 is the flywheel, the function of which is to store energy for a part of each cycle and deliver the same to the transmission system during the remaining portion of the same. The very fact that a flywheel is capable of absorbing energy is reason for believing that it must be securely held in place. Were the flywheel to come loose it would do much damage, the reason for which lies in the amount of energy which would be set free in so short a time. As a rule, the flywheel is flanged F2 to the crankshaft and the holding bolts B5, of which there are usually six, should be tightened up, and it would be a good idea to see that they are properly locked into permanent relation.

Lubricating oil L1 is held in the pan at the bottom of the case and the cock C1 is placed to afford a means for drawing off the oil at frequent intervals. It will be proper for the owner of a new automobile to draw off all the oil before the car is taken out, and after cleaning out the case, new oil, of a proper grade, should be put back. The oil pump, if it is located in the case P1, should be examined to see if it is in good working order, or, if it is located elsewhere, it may be examined for the same purpose. The pump drive will demand a moment's attention and if a "dog" is utilized in the system of driving, it will be well to observe if the parts are tight and in good working order.

The connecting rod bearings B1, B2, B3 and B4 should be so fitted that there will be little heating, and, if the case is provided with a hand-hole, it will be a simple task for the autoist to remove the cover, take ahold of the connecting rods, one after the other, and feel the shake or lost motion. There should be a little lost motion, but not enough to be more than barely noticeable.

LIST OF TOOLS TO TAKE ALONG

1 8-inch Stillson wrench.
1 14-inch Stillson wrench.
1 Hawkeye Stillson wrench.
1 6-in combination pliers.
1 10-inch combination pliers.
1 machinist's screw plate with taps and dies in hardwood case, for 3-16 to 5-8-inch U. S. thread.
1 adjustable hack saw frame.
2 dozen hack saw blades.
1 8-inch Coe's monkey wrench.
1 12-inch Coe's monkey wrench.
1 set of S wrenches for 1-4, 5-16, 3-8, 7-16, 1-2 and 5-8 hexagon heads.
1 B & S adjustable spanner wrench.
1 geared breast drill with Morse twist drills up to 5-8 inches in diameter by 1-32 increments, preferably of high speed steel with duplicates of below 1-4 inch.
1 substantial gasoline blow torch.
1 pound of stick solder.
1 package of soldering flux.
1 substantial hand vise with jaws to open 1 inch.
1 6-inch round second cut file.
1 8-inch round second cut file.
1 12-inch round second cut file.
1 8-inch half-round second cut file.
1 12-inch half-round second cut file.
1 10-inch half-round bastard file.
1 10-inch half-round smooth file.
1 8-inch flat second cut file.
1 12-inch flat second cut file.
1 10-inch flat bastard file.
1 10-inch flat smooth file.
1 10-inch feather edge bastard file.
1 10-inch feather edge smooth file.
NOTE.—All files to be Black Diamond or equal quality.
1 assortment of file handles.
1 pair of circular snips, length 11 inches.
1 center punch.
1 4-inch machinist's screw driver.
1 6-inch machinist's screw driver.
1 10-inch machinist's screw driver.
1 small India oil stone.
1 2-pound ball pein machinist's hammer.
1 7-16-inch cold chisel.
1 5-8-inch cold chisel.
1 7-8-inch cold chisel.
1 diamond point chisel.
1 cape chisel.
1 roll insulating tape.
1 bundle copper wire.
1 roll 18-ounce copper.
1 sheet of asbestos packing.
1 kit of substantial tire tools.
1 set of patches for tubes.
1 package of tire cement.
1 package of acid cure for tube repairs.
1 substantial tire pump with pressure gauge.
1 foot of hose of a size to repair joints in water piping.
1 extra pair of hose clamps.
1 bundle of No. 14 B. & S. G. iron wire.
1 gallon can of lubricating oil.
1 can of grease for lubricating.

The main bearings M1, M2 and M3 are not so readily examined, but it will be possible to run the motor for a time and then feel the bearings to determine the extent of heating.

The man of no experience will make mistakes when bearings are being examined, he will find that they do heat up quite a little, and he will be likely to reach the conclusion that the heating effect is in excess. All bearings, when they are running under the most efficient conditions, will heat up so much that they will feel quite warm. Good service may be had from a bearing even when the increase in heat is all that the hand will stand with comfort.

The manifolds M4 and M5, one from the carbureter and the other from the exhaust transfer ports, should be examined to see if the holding bolts H1 are tight. If the manifolds (especially the intake) are not tight on their seats the motor will fail to perform properly. In the same way it will be a good idea to go over all the bolts and tighten them up, but the inexperienced man must be careful not to put too much pressure on, especially if a long wrench is used. It is on this account that S-wrenches are recommended; they are made in proper lengths considering the sizes of heads of nuts that they will accommodate. Even then pressure must be carefully limited to prevent pulling a head off.

1 extra tire case.
1 cover for tire case.
5 inner tubes.
NOTE.—If front and rear wheels are different sizes, provide extra tubes and cases for each size.
1 set of special tools if demanded considering the design of the automobile.
1 jack.
1 box of tire powder.
1 box cotter pins.
1 set of bolts, nuts and screws.
1 foot of proper size key stock.
1 box assorted rivets.

SMALL GARAGE TOOL EQUIPMENT

NOTE.—In addition to the tools specified for the automobile, which will be available for use in the garage the following equipment will be proper:

1 4 1-2-pound blacksmith's hand hammer.
1 20-pound blacksmith's hammer.
1 heavy machinist's pein hammer.
1 set cold chisels.
1 2-inch hide-faced hammer.
1 extra set of files.
1 7-inch toolmaker's swivel, universal vise.
1 400-pound blacksmith's anvil.
1 anvil block.
1 substantial machinist's bench.
1 scientific portable forge.
1 post drill with self-feeding mechanism. Chucks to take 3-4-inch drills and down.
1 heavy pattern breast drill.
1 extra set of high speed steel drills from smallest up to 5-8-inch, inclusive.
1 rachet drill set.
1 set of ratchet socket wrenches.
1 18-inch Stillson wrench.
1 set machinist's clamps.
1 set of spring dividers and calipers.
1 B & S combination square, with 12 and 18-inch graduated blades.
1 graduated hardened T square of medium size.
1 blacksmith's rule.
1 surface gauge.
1 depth gauge.
1 micrometer set.
1 thread gauge.
1 set bearing scrapers.
1 cross oil filter.
1 60-gallon lubricating oil tank.
1 gasoline storage tank.
1 set of oilers.
1 waste can.
1 waste storage box
1 set fire extinguishers.
1 washing set.
1 box for washing materials as soap, chamois skin, etc.
1 vulcanizing set.
1 dark closet for tires.
1 box assorted rivets.
1 box assorted bolts and nuts.
1 assortment of mild steel for stock.
1 assortment of key stock.
Such other tools as the situation warrants.

The belt B6, which transmits the power to drive the fan, should be tight enough to serve the purpose, and a general examination of all the small parts, as well as the bearings and drives for the pump and magneto, will lead up to the last point, i. e., the grinding of the valves V 1 and V 2, which are the inlet and exhaust valves in each cylinder. This is a process which will have to be undertaken sooner or later after an automobile is put into service, and it is of such importance that it will be treated as a separate matter and at some length in THE AUTOMOBILE at an early moment. In view of the wide variation in valves and the arrangement of them it is necessary to illustrate the points to be made.

AT FIRST GLANCE MECHANISM LOOKS COMPLICATED

Fig. 4 shows the right side of a four-cylinder motor in its right position in a chassis, with the bonnet off, presenting the accessories in their correct relation. To a man of no experience, a look under the bonnet must have a very disconcerting effect. The carbureter C1 occupies a midposition between the cylinders, and the intake manifold M1 completes the connection between the carbureter and the two pairs of cylinders. The magneto M2 is partially hidden by the chassis frame S1, but the wiring passes almost vertically up, thence across the top of the cylinders to the spark plugs S2, of which there are four in sight on the right side of the motor, and the timer T1 stands above the level of the cylinders in a midposition with its wiring, which passes across to the opposite side of the motor connecting with four spark plugs which are there placed. The coil C2 is on the dashboard D1, which connects to the spark plugs through the high-tension wiring system, and to the timer T1, thence to the battery, forming the low-tension system.

The steering post S3 passes through the dashboard to the steering gear G1, and the spindle of the gear connects with the steering arm A1, through a square end and a clamping bolt C3. It is extremely important that the clamping bolt C3 be examined and tightened up sufficiently to eliminate any evidence of lost motion, and if the autoist cares to disassemble the parts, he will find that the bolt intercepts the spindle when it is in place, a groove being furrowed out for the purpose, and in this way the arm is prevented from jarring off of the spindle.

The opposite side of the motor, which is shown in Fig. 5, presents the exhaust manifold M1, and the lubricator L1 is shown a little to the fore and below the exhaust manifold, partially hidden by the chassis frame. The lubricator is kept sufficiently warm in this position to serve a useful purpose, but it is important that the pipes be tightly connected and the lubricator kept scrupulously clean, in order that a glance will suffice during the inspection period, to indicate that the parts are in the right relation and in good working order. The radiator R1 is connected to the water jackets of the cylinders by a piping system, in which the rubber hose R2 and R3 complete the piping, and this method is employed in order to abort the ills of vibration by inducing a sufficient measure of flexibility.

In the operation of the car, it is necessary to avoid overheating of the cooling water, and this will be accomplished if the spark is not retarded after the motor is started. It is generally true that overheating follows if the motor is run without load on a retarded spark, and it is economy in every possible way to stop the motor if the car is to stand for any length of time.

The best position of the spark, when a motor is running, depends upon speed. This question of timing is one which will have to be taken up in the long run as a separate subject, but for the present it will be desirable to observe that the running conditions of the average motor, considering a magneto, demand that the spark be advanced from 20 to 30 degrees, depending upon the speed of the motor. This statement should be qualified by calling attention to the practice in taxicab and some other work of running on a fixed spark, in which case the advance is not far from 30 degrees, but this is not the common practice among the several builders, nor do they seem to agree as to the best fixed advance. The probabilities are that account must be taken of the characteristics of the ignition system, and it is true that there are differences in the performances of the several makes of magnetos sufficient to demand that each case be investigated upon its merit. The makers of automobiles are supposed to look after details such as this, and it will be enough for the autoist of small experience to acquaint himself with the structural details sufficiently for him to make necessary adjustments. It would be ill advised on the part of any new autoist to tamper with the ignition system. It is scarcely likely to give trouble unless it is neglected for a long period of time and it is too complicated for the layman to tamper with. The autoist who desires to enjoy riding in the absence of petty annoyances will take particular pains to keep the entire ignition system scrupuously clean and to study the particular ignition apparatus employed in his car so that its wants will be fully appreciated.

TRANSMISSION GEAR DETAILS

There are four types of transmission gear systems in common use:

(a) Planetary gear systems.
(b) Progressive sliding gear systems.
(c) Selective sliding gear systems.
(d) Friction drives.

The planetary gears are invariably housed, and they should be so well encased that semi-hard lubricant will remain within. If the case has bolted ends and they do leak lubricant, it becomes necessary to go over the bolts and tighten them up sufficiently to stop the leak. It is quite useless to attempt to run a planetary gear unless the sun and planets are substantially submerged in the lubricating material. The sun, in this case, is the central pinion, which is fastened to an extension from the crankshaft of the motor, and the planets are made up of relating square cut pinions of which there are either two or three sets disposed around the periphery within the case, the idea being to establish a balanced relation, which could not be done were there but one planetary set rotating around the sun. It is true, however, that a single planetary set would serve from a purely mechanical point of view, disregarding static and kinetic balancing conditions, of course.

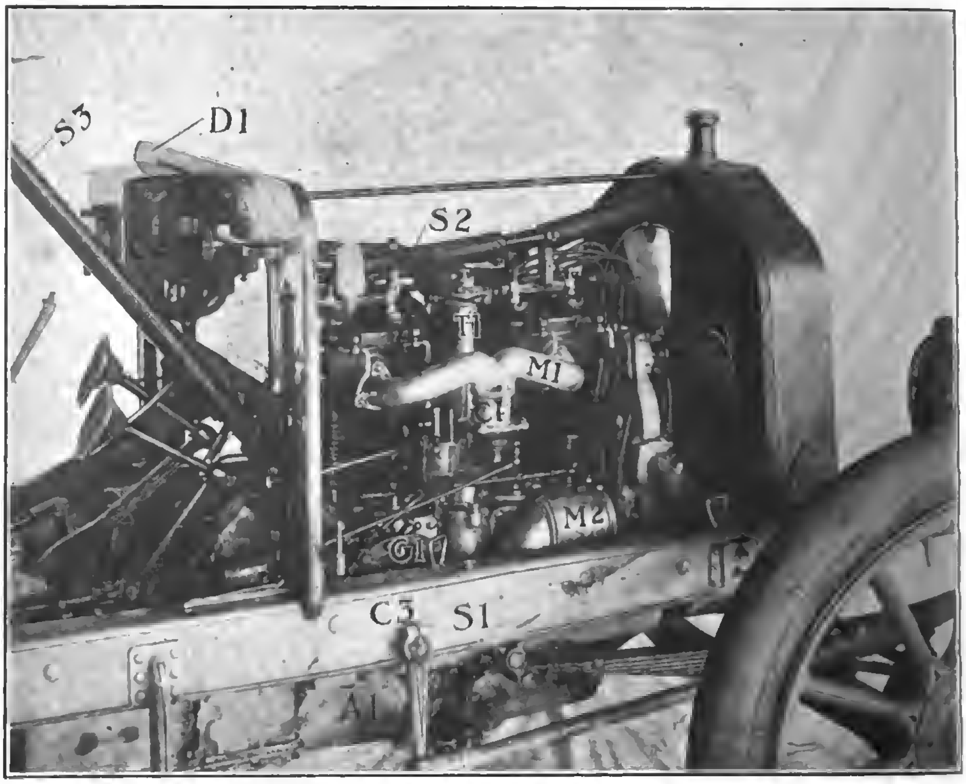

Fig. 4—Right side of a 4-cylinder water-cooled motor used to point out relations of accessories and relating parts

When the planetary gear is in the position which drives the car at the maximum speed (on high) the entire set of planets, and the relating sun, rotate as a unit, and the only work which they do is that of transmitting the torque of the motor, so that if they are strong enough to stand the torque stresses, there is nothing more required of them, and the transmission is done noiselessly and well. When the second speed is utilized (also reverse) the planets revolve around the sun, and, no matter how well the system is made, it is apparently impossible to so perfectly fit such an intricate system of gearing as to eliminate noise entirely. Grease seems to be the cure for this noise tendency, and the only danger lies in allowing the grease to remain within the case too long. The new autoist may take it for granted that the lubricating qualities of grease or oil wear out in time, just as everything else depreciates, and when these lubricating qualities depart from the mass, what is left is a slimy grit holding non-lubricating product, which it is well to be rid of. Perhaps kerosene oil, if it is forced in by means of a gun, will help to rid the internals of the case of this undesirable worn-out grease, but if the autoist does not like the undertaking which he may thus impose upon himself, the remedy lies in selecting a rather heavy grade of lubricating oil, instead of semi-hard grease. The trouble with the lubricating oil is that it will not stay in unless the case is quite tight. Under the circumstances, a good deal of importance should be attached to having a tight case on a planetary gear.

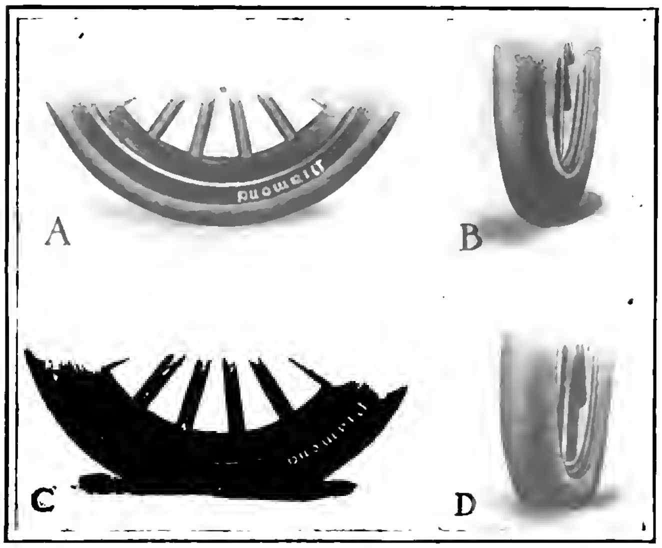

Fig. 3—Diamond tires under different conditions of air pressure and used to illustrate the need of proper inflation

Considering sliding gears, there are certain details which may be regarded as common to them, whether or not they are selective or progressive in their scheme of design. Before proceeding it may be well to point out that in the progressive system, which is used on a very few of the larger and more powerful cars, it is impossible to slide from one speed to another shifting and skipping at will. It is what the word implies, the sliding members are so arranged that the speeds are changed from low to second, to third and fourth, or vice versa, and from low into reverse. In the selective system, the operator may slide the gears for any one of the combinations at will, but it devolves upon him to maintain a proper relation as between a gear ratio, speed of the car, and ability of the motor.

With a new car, it would be a good idea to remove the handhole covers from the top of the transmission gear case, take out all of the lubricating material therein contained, wash the system out most thoroughly, and inspect all the bearings, the bottom of the case, and the crevices everywhere, with a view to making sure that there are no stray bolts, nuts, or other foreign substances laying around loose. The next operation will be completed when it is determined for a certainty that the gears register with each other with flush faces when the lever

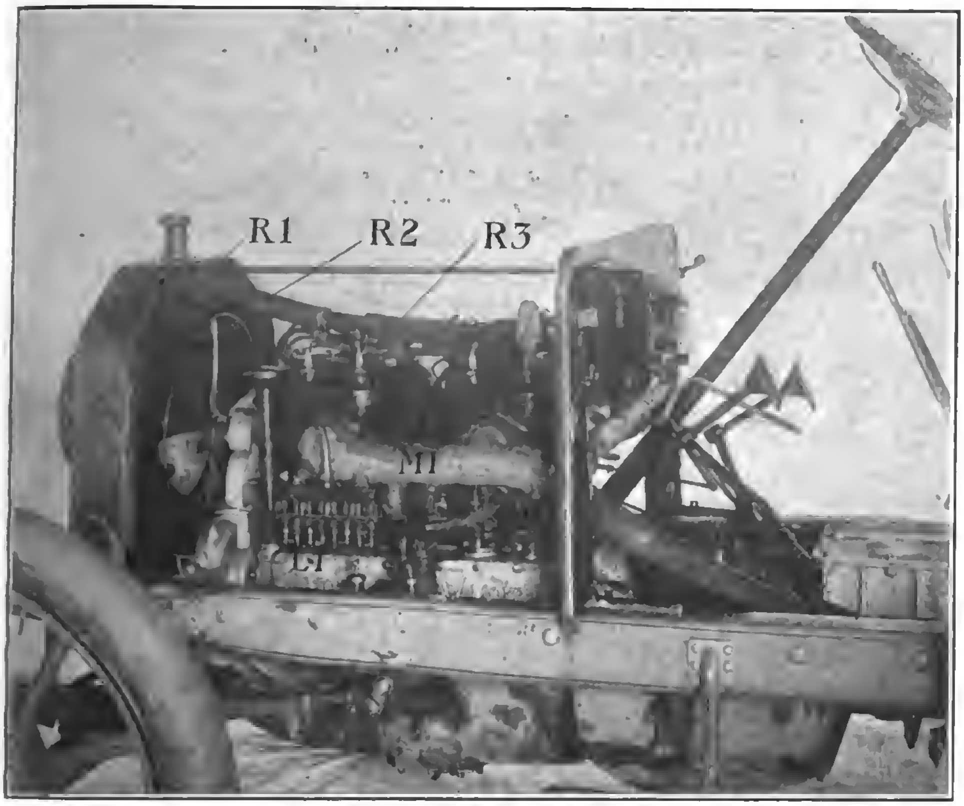

Fig. 5—Left side of a 4-cylinder water-cooled motor in a chassis showing the location of the oiler and manifold for the exhaust

The leather faced clutches are usually provided with flat or other suitable springs by means of which they are pressed into intimate contact with a relating member of the clutch, and unless the leather is maintained in a pliable state free from the excesses of lubricating oil, it will slip, and if it does slip, the excess heat generated will char the leather and it will cease to be pliable, after which it will fail to serve any useful purpose at all. The remedy lies in keeping the clutch free from accumulation of oil, and to permit soft but firm engagement, rather than to allow the clutch to slip. The other types of clutches should be kept clean, free from excess lubricant and in order.

STEERING ADVANTAGEOUSLY

Racing drivers, despite their apparent carelessness, may well be patterned after by those who have yet to learn the best way to grasp the steering wheel and be in a position to act in precise accord with the varying requirement. Fig. 6 is taken as representative of the racing driver's position, and attention is called to the point on the rim below the horizontal center, where the right hand firmly grasps the rim with the forearm horizontally disposed, describing a right angle. Inexperienced autoists take a hold of the wheel very much as if they were afraid of it, and with both hands they hang on, generally grasping the rim at diametrically opposite points, or, what is worse, at points above the horizontal center. The arm muscles, under such conditions, are in the position of the greatest disadvantage, and body bracing becomes impossible. The illustration is sufficiently clear on this point to require no further discussion at length, and it is recommended that inexperienced autoists study this situation until they are able to determine for themselves the most natural and advantageous position it is possible for them to assume, considering the location of the wheel, with respect to the seat, in the car they elect to drive.

is thrown into its respective notches. Unless the sliding system is properly adjusted, the mating gears will not register with each other, and if they overhang, it follows that the work will not come over the whole face of the engaging teeth. Under such conditions it is only a matter of a short while when the faces of the teeth will have furrows worn in them, and it is just possible that the teeth will be broken off because the work will be concentrated upon a relatively small section of the metal. Then, too, the pressure will come on less than the whole surface at the pitch line, and this may be the cause of additional trouble. If it is found that the registry is not perfect, there is nothing to be done but to make such adjustments as will overcome the difficulty. It is not a situation to be tolerated under any circumstances.

It will be well worth while to examine the bearings before putting the cover back on the transmission gear case, and if possible they should be thoroughly washed and especial notice should be taken of the presence of any foreign matter as metal filings or other hard substances which, if not removed, would destroy the highly polished surfaces of the balls, and score the raceways as well.

In view of the presence of ball bearings which owe their great utility to the use of alloy steel of particularly hard selections and highly polished surfaces, care must be exercised in the selection of the lubricant which is to be used in the transmission gear-case and in the ball-bearing housings. If the lubricant has an acid reaction, or if it is made up of materials which will soon bring about the destruction of the polished surfaces of the balls and the races, thus introducing a high depreciation factor of the car as a whole, due to the relatively high cost of the bearings.

The autoist will have to deal with some one type of the clutches, as follows:

(A) Leather faced cone clutches.
(B) Leather faced cone clutches with cork inserts.
(C) Multiple disc clutches.
(D) Dry-plate clutches.
(E) Disc types of clutches.

Fig. 6—Offered to illustrate the manner in which racing drivers grasp the steering wheel

How Efficient Lubrication Reduces Maintenance

BODY of lubricants while it is hard to define and equally difficult to measure, may be arrived at from a consideration of its results, which, after all, is the desideratum. Thus, this desired quality may be found as follows: Select the lubricant for which the body quantity is desired, test it in any recognized means for coefficient of friction. Then turn through some known or measurable angle of torsion, retaining the same size, same load, same pressure per square inch, and same temperature, measuring the coefficient of friction for the same oil again. This will give a series of results for the same oil under similar conditions, but for different angles of torsion, from which results proper deductions may be made.

One series of tests which were made some time ago resulted as follows:

WINTER STRAINED LARD OILS

Test Number	Torsion in Deg.	Coefficient of Friction	Temp. F.
1	33	.0233	72
2	26	.0176	—
1	31	.0218	—
2	24	.0169	—
1	30.5	.0215	—
2	23.5	.0166	—
1	29.5	.0208	—
2	23	.0162	72

ENGINE OILS.

Load 200 lbs.	Pressure 1,700 lbs. per sq. in.		
29	11.5	.0124	69
28	15	.0161	69
29	11	.0118	69
28	15	.0161	69
Load 100 lbs.	Pressure 850 lbs. per sq. in.		
28	8.5	.0182	120
29	4.0	.0086	120
28	6.0	.0107	120
29	3.5	.0075	120

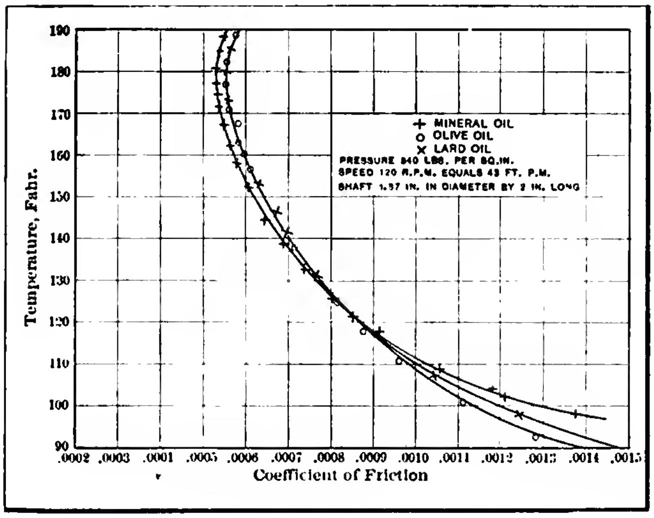

Fig. 1—Result of test showing relation of friction to temperature

From the above record of tests, one may make the deduction that, while the coefficient varies with any one oil, the one effecting the greatest reduction in friction, as indicated by the resulting coefficient of friction, is readily selected and may be considered as having the greatest body. Thus, specimen 29, varied from a coefficient of friction of .0124 at 69 deg. F. and a 15 deg. angle, under a pressure of 1,700 lbs. per sq. in. to as low as .0075, at an angle of 3.5 deg. at 120 deg. F., and under 850 lbs. pressure per sq. in. This is a reduction of .0049, or nearly 40 per cent. Specimen 28, on the other hand, shows a total reduction of but 34 per cent, being consistently higher throughout the test by nearly 40 per cent. By comparison, then, number 29 is much the better oil to use. Not alone is this true under high pressure and low temperature, but also under lower pressures and much higher temperatures. The final saving, for instance, if it could be applied to the entire lubricating system of an automobile, from the engine bearings straight through to the axle bearings, would raise a brake horsepower at the wheels figure from say 25, a fair average, to 35. This, too, without any additional weight or other disadvantages. Body then, is of prime import.

The above tests bring out another important point, namely, that the product of the coefficient of friction and the pressure is practically a constant, so the total frictional resistance is not affected by a change of load on the bearing, because of the hyperbolic nature of the coefficient curve.

While much of the theory of lubrication, as to work done, heat generated, pressures, and many other quantities, is involved, it is not so involved but that it may be readily followed through by anyone deeply interested in the subject. Thus, considering a bearing having a radius r_1, a length l, turning at n revolutions, with a mean intensity of pressure p, distributed over an angle of rotation θ, then the work done is:

$$\text{Work } U = 2\pi r_1^2 f p l n \theta$$

In which, the additional quantities, not mentioned above are: f is the mean coefficient of friction, U is the work done in turning the shaft in the bearing through the angle θ.

If there is no pressure from the bearing cap, θ equals π and the equation assumes the form:

$$U = 2\pi^2 r_1^2 f p l n$$

Again, with a tight bearing cap, θ may equal 2π, in which case the equation becomes:

$$U = 4\pi^2 r_1^2 f p l n$$

from which equations, the fact is deducible that with a fixed load, the intensity of pressure varies inversely with the area, so that the quantity $p l r_1 \theta$ becomes a constant, and the work of friction and energy wasted become proportional to the diameter of the journal or shaft. Both of these are independent of the length, except as it effects the coefficient of friction. In that case:

$$U = 2\pi K$$

K being a readily determinable constant.

Since the heat due to friction is proportional to the work done.

$$H = \frac{U}{J}$$

in which, U represents the work done, and J, the mechanical equivalent of heat.

Now, in a perfectly lubricated bearing, a theoretical case but one which is closely approximated by a flooded bearing, in which an excess of oil is always present, the distribution of pressure is:

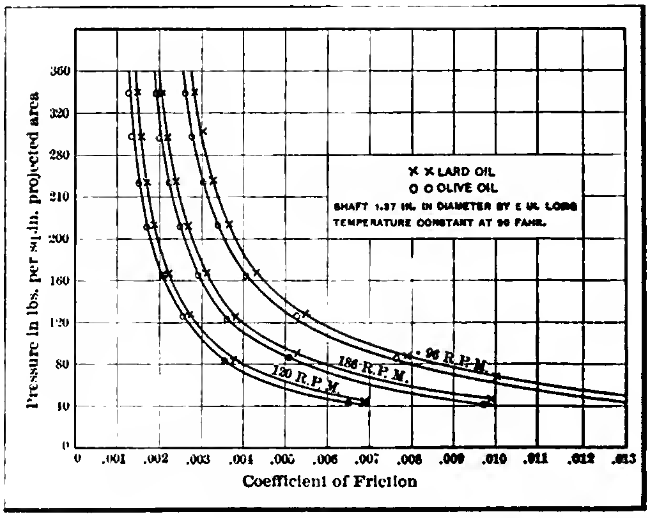

Fig. 2—Test curves showing how friction varies with pressure

$$N = p\, l\, r_1 d\theta$$

and p equals N cos θ
so that the load is:

$$\text{Load } W = \int p\, l\, r_1 \cos\theta\, d\theta$$

p varies greatly, but at intermediate points it is a constant, or enough so that it may be accurately measured. When so measured and introduced into the formula, the latter becomes:

$$W = p_1 l\, r_1 \int \cos^2\theta\, d\theta$$

which is to be integrated between the two limits of θ equal to

$$+\frac{\pi}{2} \text{ and } \theta \text{ equals } -\frac{\pi}{2}$$

In any one element of the bearing, the total force of friction is shown by the equation:

$$f\, p = \frac{.64\, W \cos\theta}{l\, r_1}$$

in which the normal variation is between the two extreme values for the angle. These values are cosine θ equals zero, in which case, the angle is 90 deg., and for an angle of zero, in which event, the value of the cosine is a maximum at 1. In this latter case, the equation simplifies to:

$$f\, p_1 = \frac{.64\, W}{l\, r_1}$$

The total pressure on the bearing is then:

$$P_1 = .64\, W \int_{\theta = -\frac{\pi}{2}}^{\theta = +\frac{\pi}{2}} \cos\theta\, d\theta$$

$$= .64\, W \left(2 \sin\frac{\pi}{2}\right)$$

$$= 1.27\, W$$

from the above, the total force of friction is

$$f\, P' = 1.27\, f\, W$$

while the work of friction is

$$U = M\, a = 1.27\, f\, W\, a\, t\, r_1$$
$$= 2.5\, f\, n\, r_1\, t\, \pi\, W$$

In this, the new quantities introduced are: a is the angular velocity, t the time taken as a unit, n the number of revolutions in this unit time. By introducing the latter in the form of seconds, and thus, the British Thermal Unit, the total power lost is found from the form:

$$\frac{U}{550\, t} = \frac{2.5\, f\, n\, r_1\, \pi\, W}{550}$$

With uniform pressure over the surface of the bearing (a condition difficult to realize) the expression for the work of friction reduces to

$$U = M\, a = 1.57\, a\, f\, t\, r_1\, W$$
$$= \pi^2 f\, n\, t\, r_1\, W$$
$$= 10\, f\, n\, t\, r_1\, W \text{ nearly}$$

That the fitting of the shaft to the bearing has a large influence upon the result is obvious, the exact difference being expressed by the difference between the values obtained from the preceding expression and the following. Before wear has widened the line of contact, and since $a = \Phi$ the angle of friction, the work of friction or energy wasted is:

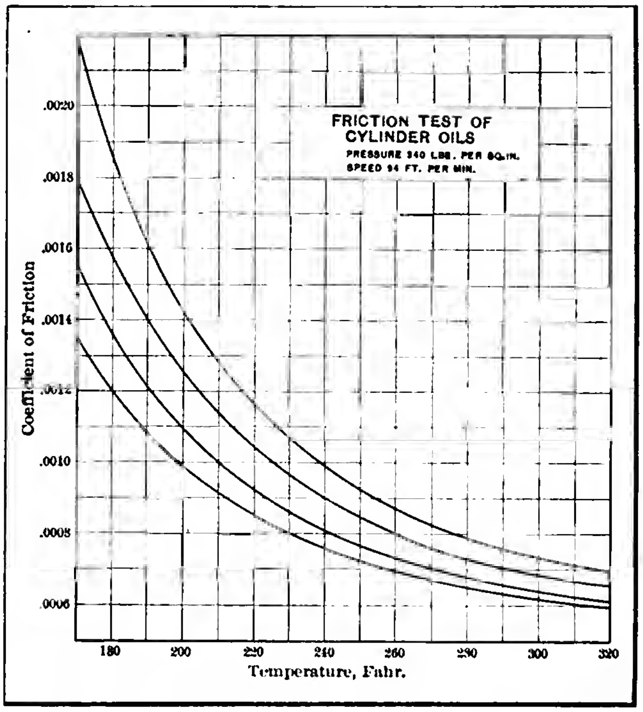

Fig. 3—Temperature variations in friction at slower speeds

$$U = W\, a\, t\, r_1 \sin\Phi$$
$$= \frac{f\, W\, a\, t\, r_1}{\sqrt{1 + f^2}}$$
$$= 2\, W\, \pi\, n\, t\, r_1 \sin\Phi$$
$$= \frac{2\, W\, f\, n\, t\, r_1^2}{\sqrt{1 + f^2}}$$

This form of shaft and bearing contact—that is, loose contact, but without wear—produces the least waste and is thus the most desirable. It is an ideal case, however, and when approached too closely, results in over-rapid wear, heating, and many other undesirable features. The ideal form, then, is not of a necessity the most practical one.

Apparent Influence of Temperature

Tests seem to show that with a decided rise in the temperature, there is an equally decided drop in the coefficient of fric-

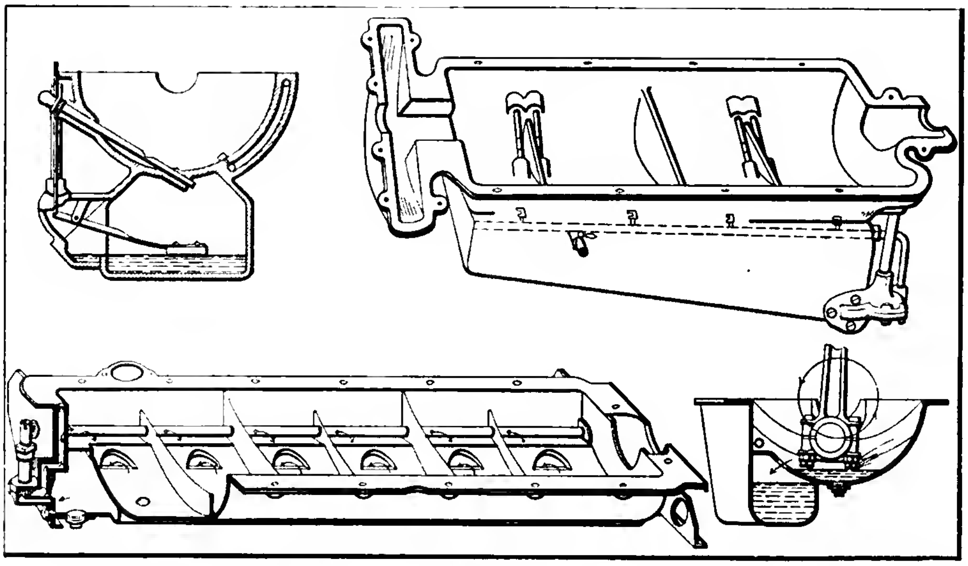

Fig. 4—Well worked out details of lubricating systems. Above, Columbia. Below, Oldsmobile

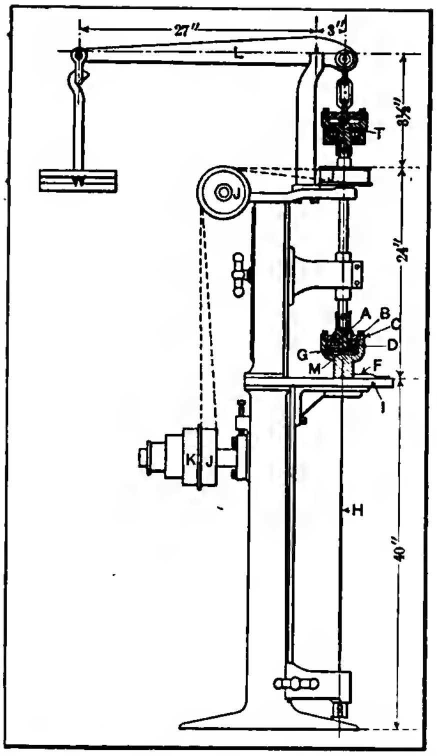

Fig. 5—Machine used in testing lubricants

tion—that is to say, from the point of view of maximum power output with minimum power input, using any one lubricant continuously, the higher the temperature the better the result.

This, however, soon reaches a critical temperature for each and every known lubricant, which critical point must be previously known, so that it may not be exceeded either purposely or by accident.

Everything said thus far has been in reference to one lubricant only, however, the results are somewhat changed when lubricants are mixed, even though of the same generic type. Thus, one test showed the following:

TEST OF SOLID LUBRICANTS FOR FRICTION AND PRESSURE

Lubricant	Speed in R.P.M.	Minimum Coeff. of Friction: Without Graphite	Minimum Coeff. of Friction: With Graphite	Maximum Allowable Press.: Without Graphite	Maximum Allowable Press.: With Graphite
Kerosene	300	.00180	.00090	290	380
"	475	.00185	.00140	290	470
"	700	.00225	.00156	290	470
Lard Oil	300	.00181	.00122	650	830
"	475	.00199	.00141	560	830
"	700	.00268	.00153	560	830
Vaseline	300	.00288	.00173	740	1100
"	475	.00280	.00210	830	920

This table shows a remarkable state of affairs. Not only is the already low coefficient of friction, in some cases so low as .00180, lowered very materially, but in some cases is actually bisected or cut in half, a reduction of 50 per cent. The last two columns of figures show items of equal importance with the friction coefficient, for the maximum allowable pressure is often of more importance than the actual saving of power. In this particular test, not only was the minimum saving as high as 30 per cent., but in several cases, it ran as high as 50 per cent. It would appear then, as if it were advisable to combine lubricants at times, this being effected with due regards for the work to be done, the necessity for a lubricant, the cost of the single components and of the compound, and the relation of the value of the lubricants, both singly and combined, to the value of the service to be rendered.

Referring again to the matter of temperature influence upon the coefficient of friction, attention is called to the high temperature work.

Thus the test made some years ago for a fire insurance company:

RESULT OF TEST SHOWING TEMPERATURE INFLUENCE
Unknown Mineral Oil, Pressure on surfaces constant at 33 lbs. per sq. in.

Temp. F.	Dynamometer Reading	Coefficient of Friction
35	8.00	.0485
40	6.12	.0371
45	5.68	.0344
50	5.36	.0325
55	5.12	.0310
60	4.95	.0300
65	4.75	.0288
70	4.54	.0275
75	4.37	.0265
80	4.29	.0260
81	4.27	.0260
82	4.25	.0260
83	4.25	.0260
84	4.28	.0260
85	4.31	.0261
90	4.90	.0297
95	6.10	.0370

Attention is called to the table above, which clearly shows that while a rising temperature is beneficial to the power saved, as exemplified by the coefficient of friction, it must also be watched with care, in order not to overtop the point of maximum saving, beyond which there is a sudden rise. Thus, while a rise of 35 deg. from 35 to 70 results in a drop in the friction from .0485 to .0275, a reduction or saving of 43.3 per cent, a further rise of but 15 deg. results in a further drop of but .0014 or less than 5 per cent. Not only that, but it brings the operation to the critical point so that a still further rise of the temperature of operation of 10 deg. results in a rise in the coefficient or loss of power of .0109, equal to 41.8 per cent, and almost overbalancing the former gain in 35 deg. rise. In short, this coefficient plotted as a curve, rises somewhat rapidly, has a rather flat top, and drops as suddenly as it rises, points at 40 deg. on the ascent and 95 deg. on the descent being practically on an equality, in fact, a consideration of these figures would seem to show that beyond the critical temperature, the drop is very rapid, much more so than the rise, rising as it does from a given point to a maximum in 42 deg. and dropping the same distance in 8 deg. Fortunately for the automobilist who must use the oils and greases, this critical temperature varies from one oil to another, very much between oils and greases, besides being different in other lubricants. Moreover, in the usual case, the range of difference is greater than in the case above selected for illustration of the point. Purely aside from the wider range, the oils and other lubricants used on automobiles have, generally speaking, a higher critical point than the one just illustrated.

(To be continued.)

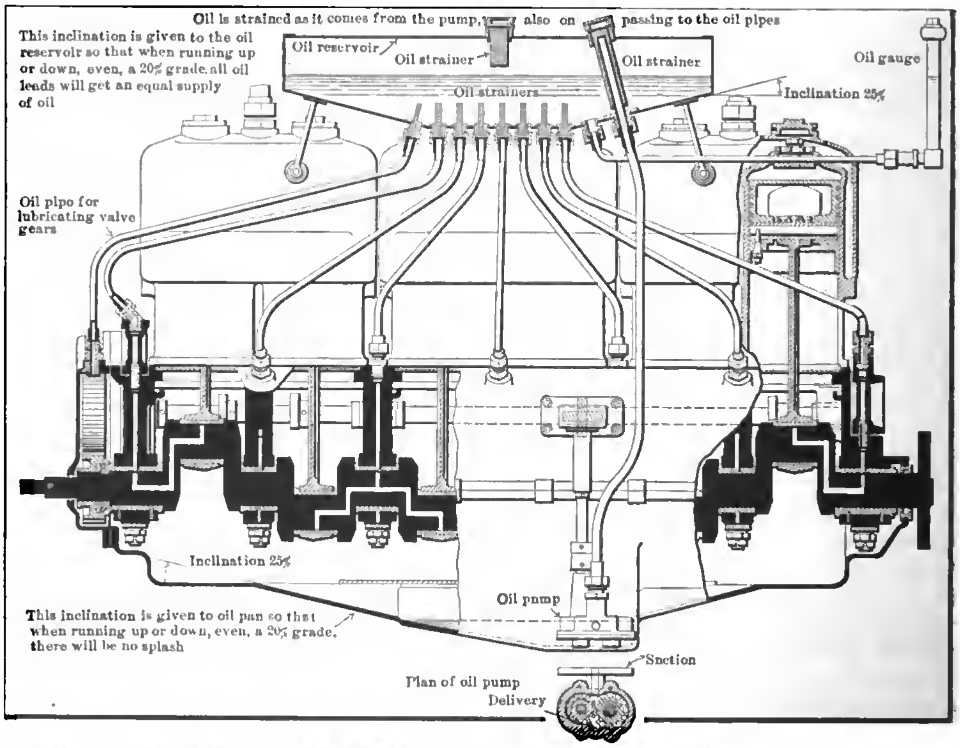

Fig. 6—Complete engine lubricating system of Pierce-Arrow cars, showing drilled crankshaft

In the Selection of a Car--Further Hints

WISDOM, if it is exercised during the process of selecting an automobile, will bear fruit in divers directions, the owner will become the possessor of a car which will reflect his needs, the service it will render might even exceed his most sanguine expectations, and the cost of maintenance will be low. If this latter condition holds, the life of the automobile will be relatively long, because a thing which does not have to be repaired at frequent intervals is bound to last the greater length of time. Wisdom is never more in evidence than it is when the automobile, as selected, is in precise accord with the service demands. It is in the process of selection that many inexperienced purchasers lay the foundation for future trouble and an increased measure of total cost. Buyers are too prone to lay undue stress upon a selling point.

STRESS USUALLY LAID ON WRONG POINT

For illustration, there is no gasoline car made which will supplant the electric in a certain field, and, as a far-fetched illustration, a banker would scarcely want to ride as freight in a five-ton truck from his office to the bank. The same idea crops out when any automobile is being selected; the right one will do the intended work, nor is a car valueless for its real work simply because it fails to satisfy a purchaser who makes the wrong selection.

It is too commonly true that intending purchasers lay stress upon the points which, while they are important, are not of the first importance. Take the location of valves: they may be (a) in the head, (b) both on one side; or, (c) as in T-cylinders, inlet on one side and exhaust on the other. Let it be taken for granted that this scheme of location is one to be weighed; certainly it is not a matter which should be compared on a basis of inferior *vice* superior material; bungling *vice* designing, or workmanship *vice* the haphazard effort of the novice.

An innovation must make good in service before it can be accepted as better than some tried device which will do the very work it is placed to do. When a purchaser places his money in hand of tried and true stability, no matter how it is clothed, it is a safe enterprise, and any other way of viewing the matter involves speculation, and the purchaser who takes this path becomes a speculator—there are good and unattractive speculations.

Speculation is legitimate within certain limits, but it is reckless when it is blind. None of the risks due to speculation are present in the mere process of selecting a motor which has the valves placed in the head, all on one side, or half on each side. Good designing will render the valves potent in either location, and, no matter where they are placed, if the materials and workmanship are inferior, the end will be disappointing.

SOME IMPORTANT CHANGES OF THE YEAR

In former times the crankcases were made of aluminum, which material was selected for lightness. The earlier efforts were attended by many a failure, due to the use of either inferior aluminum alloys or to lack of knowledge in the use of this material. The selections this year are as follows:

(a) Aluminum castings with arms of drop-forged steel.
(b) Aluminum castings with arms of the same cast integral.
(c) Cast iron upper half with aluminum for the lower half.
(d) Cast iron for upper and lower half.

Probably 50 per cent of all the crankcases made this year are of cast iron. Last year there were not more than 10 makes of motors which included cast iron in the crankcase, and, in all probability, this change in material represents the most radical departure of the year. Cast iron adds to the weight, but it is at a point of vantage, all things considered, and the total weight of the automobiles are less than ever before, due to the use of pressed steel and drop forgings instead of castings for chassis frame parts.

The engineeering side of the automobile, then, in view of several advances, makes it good practice to add weight where it will count, and subtract weight elsewhere, to compensate for such additions. It is in this class of refinements that advances have been made, and it is on this account that some critics have visited the shows and brought away the idea that the automobile designing situation is more or less at a standstill.

There is no evidence of a standstill; designing is far ahead, and it is due to the industry to point out that improvement is now being made in directions which are too subtle to intercept the eye of the critic who depends for his information upon the fact that he is not color blind; it is not now a question of the color of the finish of the body or the shape of the hood, nor can criticism be well-founded if confined to superficial matters.

MOST FOR THE MONEY IS ANOTHER POINT

It is one thing to want the most capable automobile made, and quite another matter to demand the most for the money. If an intending purchaser cannot afford to expend more than a certain sum, his first move should be in the direction of eliminating from his mind the idea that he will exact all the high-priced gewgaws that hamper automobiles, in general, and learn to limit his wants to the automobile proper, and to be careful not to go in for an "elephant." It is a moral certainty that, with a certain amount of money, but a fixed amount of good machinery can be purchased.

In a general way the cost of maintenance of an automobile is in proportion to the square of the speed it will make on the road, and in order to keep down the speed it is necessary to limit the power of the motor. This is not to say that a relatively puny motor should be loaded down by a big if not overgrown chassis. Harmony of relations of power plant to car should be maintained.

Makers are frequently confronted by demands which spell large repair accounts by purchasers who hanker after express speed when they only show a willingness to pay for a "freighter," and the only way this demand can be met is to so gear the motor that it will propel the car at a relatively high speed on a hard, level road, with disastrous results which creep in from two sources:

(a) The motor is strained when a grade is being negotiated, or, if the going is heavy as in deep sand.

(b) The high speed on a level pounds the car to junk—it is not designed for such speeds; the tire equipment is below the requirement.

According to this method of reasoning, the speed laws which are complained of as being too stringent, are in exact accord with the natural laws which place a limit on excessive cost of maintenance, and the reasons why the speed law should be respected may be summed up as follows:

(a) Depreciation will be excessive if the speed of a car is increased beyond the point as indicated by the character of the material used in the makeup of its parts, as it may be if the purchaser demands a special gear ratio in order to enable him to make greater speed on a level than is consistent with the hill-climbing ability of the car, considering the power of the motor, and when high gear is being used on the hill.

(b) If a car is thus abused it will soon reach a state of bad repair which will render it unsafe from the point of view of the public at large, and it is fair law to protect the public at large from the acts of those who have no regard for safety for themselves or others.

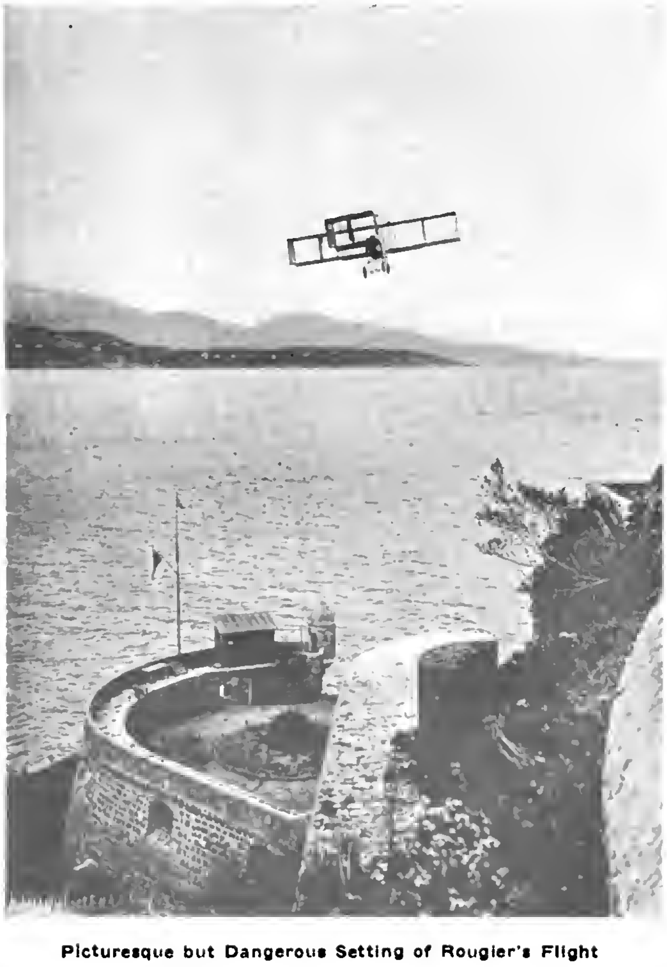
It is in these and many other ways that designers are paying attention to the problem, and it should be worth more than a little to prospective purchasers to appreciate this situation, especially when they go to select a car. Too much for the money is never to be regarded as a good purchase, and trying to beat the seller into a bargain state of mind is poor economy.

NEWS FROM BEYOND THE ATLANTIC

Rougier's Sensational Flight at Monaco

Monaco, March 14—Exactly one year ago valuable prizes were offered for flights from the port of Monaco to Cap Martin and return. The distance across the blue waters of the Mediterranean is only about three miles, but in view of the fact that there is hardly a level inch of ground on which to make a start, no aviator was found capable of winning the prize. The trip has now been made by Henri Rougier, a former automobile race driver, now a Voisin pilot, without the attraction of a big money prize. Rougier returned from the Egyptian meeting, had the big cases containing his aeroplane shipped to Monaco, occupied two days in fitting up the apparatus, then, after a dynamometer test of the motor, flew across the water.

The feature of the flight is that a start had to be made from a jetty 130 feet wide and 350 feet in length, with the harbor on the left, a perpendicular cliff on the right, and at the end a sea wall 35 feet high which must be cleared after this unusually short run. It is necessary to come back to the same place to make a landing, for this is the only level portion of this town nestled in clefts of the rock. In order to prevent aeroplanes and their pilots dashing themselves to pieces against the sea wall, the Monaco committee last year built a steeply inclined plank road from the jetty to the top of the wall, the inclination being so great that unless an aeroplane had got sufficient lift to clear the wall it would in all probability be brought to a stop without damage being done.



Picturesque but Dangerous Setting of Rougier's Flight

This track has remained in position, but was not used by Rougier, for immediately full gas was given to his motor he shot away, rose quickly, cleared the wall, and in a few seconds was hovering at a great height over the sea. Cap Martin having been rounded, the return was commenced. The aeroplane flew over the Tir aux Pigeons, now black with spectators. It appeared but a stone's throw to the harbor below, but in order to reach that narrow ledge it was necessary for Rougier to swing out to sea, then head in again parallel with the cliffs and the path. A landing was made in correct style. the machine pulling up after a run of only 100 yards. The trip had occupied a quarter of an hour.

Paris Show Settled by Club's Withdrawal

Paris, March 14—After one month's hard fighting, the Automobile Club of France has been forced to give way before the combined constructors and withdraw entirely from the show business. According to an agreement which has just been arrived at, the next Paris Salon will be held by three automobile manufacturers' associations and one cycle makers' syndicate, under the patronage of the club, and with Baron de Zuylen, president of the club, as honorary president of the joint committee. For the first time in eleven years the Automobile Club of France will have no voice in the management of the show.

The authorities now responsible for the automobile exhibition in the Grand Palais are the Syndicate of Automobile Constructors, with M. Peugeot as president; the Automobile Syndicate, an affiliate of the Automobile Club of France, with Marquis de Dion at its head; the Cycle and Automobile Syndicate, presided by M. Darracq; and the Syndicate of Cycle Manufacturers. The three automobile bodies will each take 30 per cent. of the net profits of the show, leaving 10 per cent. for the cycle makers. By reason of this agreement, the understanding between the Syndicate of Automobile Constructors and the aeroplane manufacturers for the holding of a joint show, has been withdrawn. The aeronautical men will now hold their own show in the Grand Palais during the last fortnight of October, and the united automobile salon will take place in the same hall the first fortnight in December.

The new committee will inaugurate numerous changes in the method of holding the show. Gustave Rives, the genius of the fairy-like exhibitions which came to an end in 1908, has been asked to withdraw, and his place has been taken by M. Gobron. a manager who will have to work on more economical lines. It is the intention of the manufacturers to hold an important exhibition, for the feeling is strong that an effort must be made to put Paris back into the premier position as an automobile center. At the same time there must be no unnecessary expenditure on decoration for decoration's sake. Stands will doubtless be of a uniform type throughout, provided complete, ready for receiving the exhibits, at an inclusive cost. There will be drawing of lots for positions, but not on the previous basis of first reserving the central stands for the oldest established or the most important racing firms. Everybody will now be treated alike. It is very probable, too, that the show will only remain open twelve days instead of three weeks, as formerly.

There is a strong feeling that government influence has been brought to bear on the various parties in order to lead to this settlement of the difficulty. The club protested against the aero manufacturers receiving the automobile industry into their exhibition, and the automobile firms, on the other hand, maintained that they were ready to work with the club if reasonable terms were put forth. As the government gives the use of the Grand Palais gratuitously, it was an easy matter to give a hint to the aeronautical group that the hall was not loaned for a joint show, and at the same time advise the club that it had engaged upon a useless struggle in trying to fight the automobile manufacturers. As the club, however, had an option on the Grand Palais, and the manufacturers had not, it was only possible to hold the show by giving that body a nominal share in it. This was done by asking the club to patronize the show and put its president, Baron de Zuylen, in the position of honorary president.

Paris Omnibus Company Renews Monopoly

PARIS, March 14—The only automobile firm in Paris which has reason to be satisfied with the recent floods is the company holding the monopoly for the motorbus service. During the height of the flood most of the trolley cars were stopped, the entire subway service was put out of commission, and even now, when there is not a single flooded street in Paris, only about one-tenth of the underground lines are in service. This was the opportunity of the bus company, for, as its garages were on high ground, no damage could possibly be done to the vehicles, and if streets were flooded it had only to change its routes to those that were free of water. The subway having disappeared as a competitor, it has been possible to run lines that were formerly unprofitable with very great advantage. There is, indeed, such a demand for buses that the company has been obliged to appeal to all automobile manufacturers who have previously produced experimental buses to loan them for the present occasion.

On the Hotel de Ville-Porte Maillot line a most miscellaneous collection of power buses is to be seen. The group comprises the standard four-cylinder Eugène Brillié, Darracq-Serpollet steamers, Renaults, De Dion, Diétrich, Brasier front-drive, Clément-Bayard and Darracq gasoline motors. The same additions have been made in other portions of the city formerly served by the subway, and in every case the buses are incapable of taking all the passengers presenting themselves. As the omnibus company had in stock large quantities of gasoline and benzol it has not had to pay the extra price for fuel that has struck taxicab drivers and private hiring firms so hard.

On June 1 the monopoly of the present General Omnibus Company in Paris will expire, and on the same day a new monopoly for forty years will be entered upon by the same body. The city, however, will have the right to purchase the undertaking at the end of ten years if considered desirable. The new order of things will see the introduction of an all-mechanical service for Paris, one of the conditions of the new contract being that the horses still remaining in service shall be withdrawn as quickly as possible and their place taken by gasoline or steam vehicles. Starting from June, 1910, three years are given in which to abolish all the horses, at the rate of not less than 200 reformed vehicles a year.

The present buses in service are two-deckers driven by four-cylinder Eugène Brillié motors running on benzol. It has been decided that the upper deck shall be abolished, and that the new buses shall have a capacity for not less than 34 passengers. This change has been expected for some time, it being felt that the present buses were too large and heavy for the most efficient service. Dwellers along the routes strongly protest against the noise and vibration which the vehicles occasion. The company is free to buy its buses wherever it desires, but must submit them to a municipal examining board before putting them into circulation. Up to the present the only specially-designed single-deck buses that have been used in Paris are four-cylinder Renaults, the first of which were mounted on triple rear pneumatic tires and twin pneumatics in front. Recently the same buses have been run with solid rubber tires in the rear and pneumatics in front. A number of the two-deckers have been converted to single-deckers, but as they are too narrow in the track and are unnecessarily heavy for the reduced load they have not been a success. Attempts have also been made to utilize old horse material by fitting a front drive.

Automobile manufacturers are anxious to get hold of the omnibus company's contracts, for the new regulations practically stipulating that all the present vehicles, whether horse or mechanically driven, shall be replaced within a limited period, there will be over one thousand new autobuses to furnish. Motors using alcohol or benzol will probably be favored, as the Paris tax makes gasoline too expensive for profitable working.

Graphite, What It Is, Where Found, and How Used

NOWADAYS the necessity for proper lubrication is being appreciated at its full worth, and in the automobile business is having its proper result, this being apparent in greater mileages per given weight or quantity of fuel, increased life of mechanisms, lessened care, lowered repair bills, and in many other ways. With this idea in view, a short mention of some of the more important lubricants will be of interest.

Graphite exists in two forms—crystalline (or flake) and amorphous. It is known to the trade by the names of black lead, plumbago and graphite. Black lead usually refers to the inferior grades of graphite, plumbago to the Ceylon product, and graphite to the American product.

A distinguishing characteristic of graphite is its unctuous quality, and all graphites have this quality, the crystalline more so than the amorphous forms for the reason that when a crystal of graphite is broken the cleavage surface is smooth, while in the case of amorphous graphite, and because it is amorphous, the line of the fracture is necessarily irregular and rough. It is only when the irregularities are worn away that such a surface becomes smooth and unctuous.

This quality (unctuousness) is usually determined by rubbing between the thumb and finger. However, this method does not give entirely satisfactory results for reasons as follows:

Crystalline graphite, either flake, needle-like or irregular, is dense and compact, and not easily reduced by crushing between the fingers, so that the individual particles maintain their size and continue to be easily felt; while, on the other hand, the amorphous kinds of graphite, both natural and artificial, continue to be reduced in size until the particles no longer are evident to the touch, and the "unctuous" sensation comes into evidence.

A true lubricant has been described by some of the promoters of the suspension of graphite in oil as "a body that will subdivide so that all movement will be within itself and not between it and the adjacent metal"; also that a perfect suspension of graphite and oil "is of a nature that permits of slipping within its own mass without any expenditure of energy that will produce high temperature."

The close connection of the definition of a perfect lubricant and the mention of graphite as possessing the qualities of a perfect lubricant are deceptive. This definition of a true lubricant is a very excellent one, and describes perfectly a liquid or semi-liquid substance where the material adheres to both friction surfaces and the globules between are in constant movement one on the other, but no stretch of our imagination can enable us to conceive such a condition when considering graphite, which is a solid substance and which requires considerable force to rend the particles asunder.

A mixture, as indicated above, of graphite suspended in oil has no particular advantage over a non-graphited oil as a lubricating material, because the particles of graphite, being in perfect suspension, cannot break through the surrounding film of oil or easily become attached to the metal surfaces. They simply move about in the oil film without at all decreasing the viscosity of the oil itself, the only way in which any reduction of friction could be brought about. In fact, a mixture of finely divided graphite and oil has a higher viscosity than that of oil alone, and so reduction of friction is not to be sought along this line.

One of the real functions of graphite as a lubricant is to keep the metallic surfaces apart. This result would be obtained by the presence of any solid material, such as sand, carborundum, or any abrasive substance, but that these have no value as lubricants is obvious. The separating substance, in addition to keeping the surfaces apart, must not in any way detract from the smooth, frictional surfaces, and, on the other hand, must make them smooth when they are rough. Graphite fulfils these requirements, provided it becomes permanently attached to the surfaces. A reasonable doubt might be entertained as to whether graphite can readily become attached to the frictional surface if it is so fine that it passes through the pores of filter paper, as is claimed (by some), which would indicate that the particles of graphite are surrounded by an unbreakable oil film. But if these particles could become attached to the frictional surface, efficient but not lasting aid to lubrication would certainly result.

As was said, amorphous graphites are extremely friable and easily worn away.

"Place a very little amorphous graphite on the palm of the hand and rub with the finger and notice that it cannot be rubbed off." The above has been cited as an evidence of the adhesiveness of amorphous graphite, but go a little farther: wash and dry the finger between repeated rubbings, and it will soon be noticed that the finger slides over the palm with difficulty, though the graphite still appears to be there. Now, what has happened? Simply that the graphite, being so friable, has all been worn off the high points, while enough remains in the depressions to give the idea that it is all there. The very fact that the rubbing finger continues to get blackened between washings shows how easily the amorphous graphite wears away.

Now place some crystalline graphite, preferably in some flake form, in the hand and repeat the experiment, and note how much less rapidly it blackens the rubbing finger.

In all friction surfaces there are irregularities both above and below the normal surfaces. It is the irregularities above the normal that cause the trouble, and it is important that whatever surfacing material is used should be able to build up the surfaces to the level of high points, rather than to simply fill up the very minute pores of the metal. It is not conceivable that any particle of graphite small enough to go through a filter paper could become impaled on one of these projecting peaks, but such a result is entirely possible when the broad flake is used. Even on smooth surfaces the flake form of graphite adheres with wonderful persistence, and its resistance to wear, due to its smooth crystalline surface and compaction, is remarkable.

Every one knows how difficult it is to sweep up a small, flat piece of paper, like confetti, from the floor, and the same reasons which cause the paper to adhere to the floor cause the flake of graphite to adhere to the surface of the bearing which it is intended to lubricate.

Standardization Talk Universal, Nowadays

SO much is being said nowadays about standardization, and its possible working out in the near or more remote future, that anything said on the subject is pertinent. In a recent issue of the *Motor Trader* (English) the following remarks were made under the caption "Standardization as a National Essential":

"A lecture by the president of the Engineering Standards' Committee—Sir J. Wolfe Barry, K.C.B., etc.—recently delivered before the Institution of Engineers and Shipbuilders of Scotland, will aptly serve to again voice the necessity for attention to standardization in the motor trade, perhaps the greater need of the day when its financial condition furnishes the uppermost problem. The fact that this subject is being so persistently presented to and discussed by the older branches of the engineering trades, those branches, too, that have subordinated the elements of design to the absolute requirements of commercial economy combined with efficiency to the user, is some indication that the ultimate trend of any branch of trade concerned with a mechanical output must make for standardization as a business necessity if not an inventor's ideal. As the author pointed out, standards exist for art and literature and as a means for assessing the every day economies of life. Without our weights and measures' standards, imperfect though they be, business could not be conducted, for it is of their essence that they control the sale and exchange of a variety of commodities. The appreciation of some such purpose of a systematized production has been rife in the mechanical industry as a whole since 1841, when Sir Jos. Whitworth introduced his standards of screw threads. It is true that for several years the ideal thus epitomized was overlaid by the prosperity of the industry which with the world for its mart had no pressing reason for producing by a system of uniformity or standards, and rather courted diversity of practice as the more evidence of a trade expansion that then seemed almost illimitable. With the altered conditions of modern trading, partly brought about by the supplanting of hand-wrought processes by machine and repetition methods of manufacture, and even more so by the greater diversity of the quarters whence they emanate, uniformity of parts' measurements and to a degree of the bare essentials of design became a necessity of commerce rather than as at the earlier period an ideal of the far-seeing organizer. The now stable position of the standardization movement is but of recent attaining. The success attending it has been great, but the efforts of the committees of organizers and of the sections of trade intimately concerned with the task of collating the evidence and suggestions of their members have been vastly greater. Reference to the reports of these sections, or at least such as have some relation to the industry, has been made in these columns periodically. It is to be feared, however, that the motor trade is as little alive to the importance of standards for the essentials of chassis as to some other factors making for the internal economy of the trade. Sir J. Wolfe Barry's paper furnishes numerous illustrations of the appreciation of the engineering trades of the efforts of himself and colleagues, but none that the motor car branch has at all risen to the demand. It is not so in France, the trade's greatest competitor. There standardization exists and with it no lack of progress in design, but the designer first lays hold of what is available cheaply by organized repetition methods and fashions his ideal so as best to comprehend as much of them as can be availed of. The experience of all modern manufacture is entirely against an unrestricted scope to the designer, or, to put it alternatively, the merit of a successful mechanical product is in the cheapness with which it can be made, maintained, or its parts replaced. There is no restriction of merit or talent in this environment, and no limitation of the trade's commercial scope of activity. The public demand for diversity in style and to a degree as regards essentials can truly be more adequately satisfied by a production based on a large output of many parts organically units, and structurally similar, than on a system that necessitates as many drawings, fixtures, and an administration that must consume most of the available profit.

Further Possibilities of Standardization

CONSIDERING standardization as a factor in reducing cost, it is strange that designers are not more alive to the possibilities of incorporating into their designs standard measurements for connecting rods, front axles, and other drop-forged parts in which the cost of the dies is important. Although the making of pressed steel frames is the monopoly of a comparatively small number of firms, and the variations in pattern are correspondingly limited, hardly any two designers seem agreed as to the shape of the front axle beam, and each requires separate dies. Such procedure should not continue in a business ostensibly commercially conducted.

Another point suggested by the recent show exhibits is the prevalence of the stereotyped in erroneous design. Such was to be noticed perhaps more in regard of the steering gear of certain chassis that are claimed to have been "specially designed." The trade has accepted the behind-the-axle position for the bar, and for reasons that certainly have more sanction from the aspect of safety in the event of a collision between the dumb ends of the frame, than for any mechanical point of superiority; yet few constructors have been able to break away from the necessarily hazardous (under vibration and wear) ball-and-socket coupling for the steering link, and a still larger number seem unagreed as to the relative efficiency of the angle, or the direction of the rake of the link member. The style of constructing the pivot or axle stub centers is also unsettled, and the wisdom of getting the road wheels as closely up to the pivot centre as is possible with a shoulder pivot arm does not apparently find agreement with all constructors.

Outside the mechanical purview has to be noted with much gratitude a wider recognition of the carburetion problem. The combination of a mechanical—as distinguished from any species of automatic-spring control—means of synchronizing the flow of the liquid fuel, and of determining mechanically its volume for a given position of throttle opening seems to have commended itself to a number of students of the question, and in combination with the now accepted practice of separating the jet and primary air intake from the extra air valve, with a (heat) jacketed vaporizing chamber or trunk pipe, promises to prove no small factor towards a more economical fuel consumption. The trade should have available for such tests a suitably equipped laboratory to further the tests in this regard, and that even more important aspect of the fuel question, the garnering of data on the merits and possibilities of alternative fuels within the capacity of the country to produce. The trade has certainly available the researches of specialists in laboratories subsidized from the public funds, but such are controlled by a management necessarily independent of trade control. Hence such research work has a pedagogic or academical rather than a practical and experimental value to the trade, and results in the forcing back on their own resources the trade's own witnesses to progress and research.

Simple Formula for Welding Cast Iron

A formula for welding cast iron, developed by Messrs. A. Beltzer and C. Delcampe and published in the *Iron and Coal Trade Review,* calls for a flux consisting of 15 per cent. lithium chloride, 20 per cent. potassium fluoride and 60 per cent. potassium chloride. The cast iron surfaces to be welded are preheated, and then covered with the flux powder and heated to the melting point. Additional material is supplied from a rod of cast iron which is also dipped in the flux and presented to the joint where it melts and flows in, filling up the space and making a sound weld. It is claimed that blow-holes in castings may be filled by the addition of cast iron in the above manner and that metal may be added to defective castings to build them up where defective. In short, this can be made a "putting on" process where required. The means for heating are not given, but probably any non-oxidizing flame capable of raising the temperature to the melting point of cast iron can be employed.

Results from Testing Napthalene

NOT so very long ago, about seven months ago to be exact, there was a very spirited discussion in these columns as to the availability and general usefulness of other fuels than gasoline to automobile work, the particular cause of the discussion being some statements made concerning napthalene. This fuel, which comes in a solid state, was discussed pro and con for several issues.

However little or any of what was said then was said with a basis of actual test results. So, it is of use to present some exact figures and comment thereon, as sent out by a foreign correspondent, writing with the consent of the Technical Commission of the Automobile Club of France, which made the tests.

The results of this exacting trial were very much in favor of napthalene and it will therefore be of interest to know a little more about this fuel. The Assistant Secretary of the Technical Commission, M. L. Ventou-Duclaux, an expert chemist, has given us the following interesting details:

The use of napthalene as fuel for internal explosion motors—suggested as it was by the cheapness of this product (about $1.00 to $1.25 per 100 lb.) as compared with the costs of gasoline (about $5.00 for the same quantity)—offers several great difficulties which are in the nature of the product, and which the motor industry is trying now to overcome.

Napthalene is a hydro-carbon, and, like benzol and other different products, is extracted from heavy oils, which, in their turn, are distilled from coal tar, a residue of the production of coke and gas. The portions of these oils, which are distillated between 200 and 220 deg. (C.), are submitted to a cooling effect which causes the crystallization of the raw napthalene.

This latter is subsequently separated from the other products of the distillation by compression between sheets of tissue, in which way the liquids are separated from the solid matter. The napthalene is then purified by a treatment, with soda, which cleanses it from the phenols, afterwards it is treated by means of sulphuric acid, which separates it from the other basic substances. The napthalene is in the gas works rather a troublesome by-product, requiring frequent removal from the pipes, which it would otherwise obstruct in no time.

Until comparatively recently napthalene has only been used for preserving clothes against moths during the Summer. The development of the automobile industry has drawn attention to this valuable by-product, which, chemically, fulfils all the requirements of a suitable fuel for motor cars.

Napthalene, like gasoline, belongs to the aromatic group of organic compounds. The chemical formula describing it is $C_{10}H_8$ and belongs to the hydro-carbon group characterized by the formula C_nH_{2n-12}, while gasoline, whose formula is C_6H_6 belongs to the category C_nH_{2n-6}. The molecular percentage of carbon is greater with napthalene (93.7 per cent.) than with petrol (92.3 per cent.); and it may be stated as a general rule, that the larger the quantity of carbon the greater is the difficulty to burn it completely. As an example the methane C_4H may be given, which burns very easily, producing thereby carbon dioxide with water and steam, while petrol burns in the open air with a dusky flame, leaving a deposit of unburnt carbon. The napthalene burns under the same conditions, but with a very sooty and more heavy flame, which is a point to be recognized in dealing with it in practice.

To burn a gramme of napthalene in the chemical sense of the word—that is to say that all the carbon is to be transformed in carbon dioxide—about the same quantity of air is needed as for the same quantity of benzine. The combustion theory is quite easily established for the two products:

C_6H_6	+	$15\,O$	=	$6\,CO_2$	+	$3\,H_2O$
78 gr.	+	240 gr.	=	264 gr.	+	54 gr.
gasoline		oxygen		carbon-dioxide		water
$C_{10}H_8$	+	$24\,O$	=	$10\,CO_2$	+	$4\,H_2O$
128 gr.	+	284 gr.	=	440 gr.	+	72 gr.
napthalene		oxygen		carbon-dioxide		water

The Economy of Napthalene as a Fuel

A simple calculation will show that to burn 1 gramme of petrol, 3 grammes of oxygen or 13.04 of air are required, while the oxygen required to burn 1 gramme of napthalene is 3.07 grammes, which equals 13.34 of air. It is, nevertheless, also true that the same quantity of air will enable us to burn less easily napthalene than petrol, and to explain this it may be assumed that the carbon of the petrol has some peculiarities which are apparently not shared by that of the napthalene. On the other hand, the napthalene is a solid product at ordinary temperatures; its melting point is at 49.2 deg., while it boils only at 218 deg. To obtain the carburation of the air it is therefore necessary to vaporize the product, or at least to mix it in a liquid state with air while it is maintained at a temperature which does not allow it to vaporize. According to the tests made by Messrs. Burlat Frères, to ensure good results this temperature must not be lower than 200 deg. C. This temperature must, therefore, be reached before the motor is ready to accept napthalene as fuel, which renders imperative the starting of the engine on another fuel.

A by-pass branched off the exhaust will readily provide the heat required for melting napthalene; but it is also necessary that the pipes leading to the napthalene tank be always heated to at least 80 deg. C. If this degree of heating is not constant the crystallization of the fuel may take place, followed by stopping of the motor. The air absorbed for carburation must also be preheated before it comes in contact with the napthalene, and the admission of the air into the carbureter must be regulated with much greater accuracy than for a petrol motor, since the slightest diminution of oxygen in the mixture will cause a bad combustion of the fuel.

These conditions make the use of napthalene a delicate business, especially if it is intended to obtain from the fuel all the power it can give. Its non-inflammability when cold, the ease of handling, together with the cheapness in price, make it on the other hand a desirable product which should give excellent results if rationally employed. Why gasoline with 11,000 calories, and napthalene with only 9,620 calories, give the same power in an internal combustion motor has not yet been explained; it would be both useful and interesting to further inquire into this point.

To feed an explosion motor with a mixture of gasoline and napthalene should allow regular working under normal conditions, while realizing a great economy, especially under the existing prices of the two combustibles. The question of adopting the two, one for another, will have to be studied seriously, because it will not be easy to accommodate the new fuel to the conditions of the others, or it will have become possible to change the nature of carbon.

Now that gasoline is getting scarce, and the price—already high—being liable to go higher, the attention of all discerning automobilists who give the future a thought, is called to the above. Not only does this represent one angle of the fuel situation, and an important one at that, but it also shows that scientists are fully aware of the closely approaching end of the supply of available gasoline for an automobile fuel.

New Oscillating Engine Valve

VALVES have aroused much interest in the past year or so, primarily through the wonderful success of the Knight engine with sliding sleeve valves. Many inventors have brought out other forms of valves, possessing points of apparent superiority over either the sleeve form or the old style poppet valve, or both. One of the newest inventions in this line is that pictured on this page in several cuts, and the invention of M. S. Keyes, an automobile engineer, formerly with the Maxwell Briscoe factory at Tarrytown, N. Y.

As Figs. 1 and 2 on this page show, this invention consists of a tubular sleeve used for a valve. This sleeve has cut into its one side a number of ports, which are presented to the open combustion chamber in succession. To operate the valves—for there are but one per cylinder—the regular camshaft is used, but instead of a sliding or lifting motion, as in the case of the poppet valve, or a rotary motion as in some valves, the motion given to these sleeves is that of partial rotation followed by similar partial rotation in the opposite direction, in short, oscillation..

As Fig. 3 shows, this is accomplished from the usual camshaft by means of an L-shaped lever placed on the side of the head—for these valves are located in the head—and operated by the upper end of the push rod, this motion being restrained, and the downward motion produced by means of a strong spring, which works against the other end of the L-shaped arm, and at right angles to the direction of the push rod.

Inflow of gases and outflow of the exhaust are through the interior of the tubular form, the inlet and exhaust pipes being bolted up to the cylinder heads on the side opposite to the operation. This gives a certain amount of end thrust on the valve, both from the inflowing carbureted air and the reaction from the fast-flowing exhaust. This is cared for, as is also wear, by means of a taper end.

To take care of unequal expansion and contraction, the side of the sleeve opposite to the ports is slotted with a fine slot, which allows the valve to adjust itself to the temperature of the surrounding chamber. This slit is made large in the drawing to bring out the point. Similarly, the opening in Fig. 1 connecting

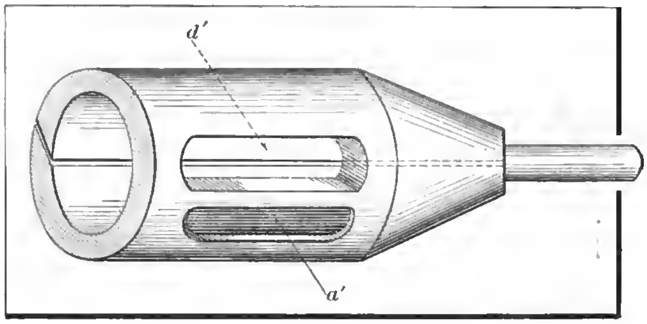

Fig. 2—Sketch of valve showing ports cut in the side

the port in the valve with the combustion chamber, is sectioned by mistake. This should show an opening, as the valve is set in the open position.

One advantage which this design has is that of calling for water jackets all around the valve, not alone below, as is common, but also above and on all sides, so as to completely surround the valve. This circular form makes this easy, without destroying the symmetrical appearance of the cylinder head. The latter is in a separate piece and bolted in position, so that removing it for an inspection of the valves, should one desire to do this, is an easy matter. To carry out the idea of a perfect combustion chamber, at least as to shape, the piston is hollowed down to a spherical shape, the part of the chamber which is in the head being similarly shaped. This form, according to scientists, gives the most nearly perfect results.

Louisville Show Opens Under Auspicious Conditions

LOUISVILLE, March 22—The Automobile Show which was opened on March 17, and was run under the auspices of the Louisville Automobile Dealers' Association, closed on Saturday night under conditions of the most unusual success from both a business and social point of view. The excellent results obtained were due to the splendid co-operation of the members of the club as a whole, the close attention to detail by the committee, and the exacting and painstaking efforts of President Prince Wells, supplemented by the good work of Vice-President E. G. Reimers, and the executive ability and indefatigable energy of Herbert Levy, secretary-treasurer.

The opening took place at 1 o'oclock in the afternoon at the First Regiment Armory, which was appropriately decorated for the purpose, utilizing the flags of all nations in graceful array, and just enough of foliage to destroy monofonous tendencies. The armory is a large one, with 54,000 square feet of floor

Some of the Exhibitors. At the Left Weber Commercial, White and Stanley. Right, Buick and Welch Stands

Along one of the Outer Aisles, Where Chalmers, Reo, Haynes, Babcock, Ohio, and Broc Drew and Held the Crowd

space in the main hall, which is known as the drill room, and 18,000 square feet of balcony space. Over 100 cars were skillfully arranged over the drill room floor, and the balcony space was adequately cared for by the accessory makers.

From a purely business point of view the show exhibited some decided tendencies in addition to the customary expectation from the touring car point of view. It soon became known among the exhibitors that the South is interested in the commercial automobile, and the visitors from afar, representing in the main the rural communities, were there in sufficient numbers to be distinctly noticeable, and their inquiries took on a utility tone. There was no time during the show when it could be claimed that the Exhibition Hall was sparse of spectators, but there were periods during which the patrons of the industry were uncomfortably numerous.

EXHIBITORS AT LOUISVILLE AUTOMOBILE SHOW

Atlas Machine Company, Regal "30," Marmon, Empire "20," Graboweky trucks; Banks Motorcar Company, Ford; Hite D. Bowman, Stearne, Rausch & Lang electrice; Broadway Auto Company, Stein tires and sundries; Andrew Cowan & Company, sundries; R. L. Davis, R. S. motorcycles; Dunham Auto Company, Velie "40" Buffalo trucks; Filton-Conway Company, E-M-F "30," Flanders "20"; C. W. Fisher, Thor motorcycles; Gloesbrenner Commercial

(*Concluded on page* 616.)

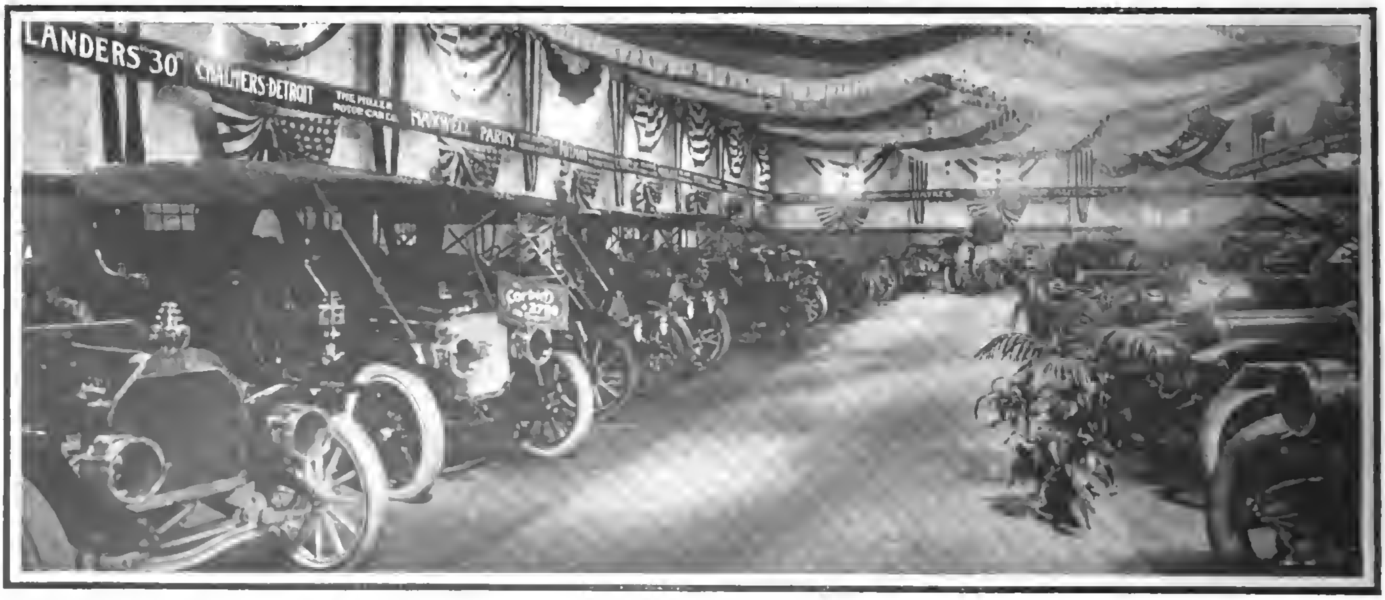
Armory Where the Exhibits Delighted the Automobiling Public of Bridgeport, the Home of Locomobile

Bridgeport Demonstrates Attraction of Shows

BRIDGEPORT, CONN., March 21—The attractions which an automobile show hold forth to the public were well demonstrated by the large attendance which has been the feature of the Automobile Show here from the opening night on. The show is held in the Armory, by the Bridgeport Automobile Dealers' Association, the officers of which feel satisfied with the results thus far.

Opening on Wednesday, March 16, the show is scheduled to continue for three days, closing on Saturday night. The opening night was marked by a crowd well in excess of 2,000 people, which is large, considering the size of the town and the hall in which the show is held.

As one enters the armory the sight is a most pleasing one. The decorative effect is excellent. As stated previously, the color scheme of the decorations is green and white. There are



Exhibits of Flanders, Chalmers, Maxwell, Parry, Pullman, Cadillac, Midland, and Speedwell Occupied One Broad Aisle

View of Spacious Main Floor, Showing in Particular the Exhibits of Regal, Paterson, Whiting and Mitchell

many American flags on the side walls, and the blending of the national colors with the white and green has made a fine combination, one which attracts much attention.

The exhibits are in the center of the hall and on both sides. The center is by no means the most attractive spot. The cars rest upon green crash, and the booths are separated by white tape. This gives a full view of the entire exhibit without the offensive break of the usual wooden railing. The elimination of the wooden railing and the use of the white tape instead is a most desirable and commendable feature of the booths. By the use of the tape the dealers have made their show much more attractive and have shown some taste.

The show was opened without much ceremony, the only thing being a speech by the Mayor, and a reply by the president of the Dealer's Association, W. D. Rantz. During the evening, music was furnished by the Wheeler & Wilson band.

Among the other attractions, Post & Lester showed a small model of a Wright biplane, which was made in France. The attendant in charge of this booth had to answer a constant fire of questions.

The way in which interest keeps up the general enthusiasm and feeling of hustle and bustle are cause for congratulation, and the auto dealers feel that they have accomplished something, as indeed they have.

Another Aisle, Along Which Were to Be Found Peerless, Marion, Mitchell, and in the Foreground, White Chassis

RECENT CLUB ACTIVITIES

NEW HEADS FOR BUCKEYE CLUB

Columbus, O., Mar. 21—The annual election of officers and banquet of the Columbus, Ohio, Automobile Club will be held March 29 at some place to be selected at a later date. A large attendance is expected, since the campaign for membership has been inaugurated. Much enthusiasm in the affairs of the club is shown.

The two tickets to be voted at the coming election have been completed by the nominating committee. The tickets follow: President, Dr. W. D. Inglis and Charles E. Firestone; first vice-president, Dr. C. S. Means and Norman O. Aeby; second vice-president, Sherman D. Brown and Charles C. Janes; board of governors, Perin B. Monypeny, Herman Foster, Dennis Kelly, Rev. J. H. Dodson, Nelson J. Ruggles, M. J. Hanley, William M. Frisbie, D. B. Neil, C. S. Krumm, Dr. George P. Stephenson, Dr. H. A. Radebaugh and H. S. Waite. Six are to be elected. The new constitution and by-laws was adopted at a recent meeting and a complete reorganization of the club has been effected. Instead of the affairs of the club being looked after by the officers everything is now in the hands of the board of governors, consisting of six members and the four officers *ex-officio*.

Every member was placed on the committee of reception for the entertainment of the delegates to the convention of the Ohio State Automobile Association, which met in Columbus March 16.

MORE ACTIVITY IN QUAKER CITY

Philadelphia, Mar. 21—The First Volunteer Motor Corps is the title of an organization of the Quaker City Motor Club, Philadelphia, Pa. It was organized two years ago with a view of quick mobilization in times of national, State or municipal danger. Several days ago, at a time when street car strike disturbance was at its highest, this force volunteered its services to the Mayor of the city and as soon as assembled they did excellent service for the Department of Public Safety. The owners and drivers have been sworn in as special police and provided with badges and arms. The president of this organization is Charles J. Swain; others connected are: P. D. Folwell, Richard Sellers, J. Fred Betz, 3rd, Edwin H. Lewis, Louis Vogel, C. Edgar Shreve, J. F. Morgan, Evans Church and Archie James.

WESTERN PENNSYLVANIA NOTES

At the annual meeting of the Automobile Club of Pittsburg, Pa., held February 21, the following officers were elected for the third year: President, Edward Kneeland; vice-presidents, Edward Kent, William N. Murray and William A. Seif; secretary, Hall C. Wolff; treasurer, William A. Heyl.

The automobile show held in Sharon, Pa., was quite pretentious. It opened March 1 and continued three days with the following as exhibitors: Buick, Rambler, Parry, Ford, Hudson, and Chalmers. An orchestra enlivened the occasion and the automobiling public, which is increasing very rapidly in the Shenango Valley, was present en masse. The show was conducted by W. C. De Forrest & Son, who made a special effort to have the decorations above the average.

SYRACUSE CLUBS EVINCE MUCH ACTIVITY

Syracuse, Mar. 21—The Automobile Club of Syracuse has made still another addition to its already large membership. At the last meeting twelve more members were elected, making a total to date of 422. This large organization has set a mark of 500, which it hopes to reach by the first of July, and it is expected by the officers that a long step toward this object will be taken at the coming automobile show in Syracuse. For the purpose of bringing this about, the club will have a booth at the show where an active campaign for membership will be carried on. The annual banquet of the club was held at the Yates on Thursday evening, March 10, the eighth recurrence of this social feature of the organization.

ANNUAL ELECTION NEXT AT CINCINNATI CLUB

Cincinnati, Mar. 21—The Automobile Club of Cincinnati having successfully carried out its first annual automobile show is now engaged in making arrangements for the annual election which will take place on March 27. Dr. C. L. Bonifield, the present head of the organization, will, it is believed, have no opposition if he again runs for the office of president. A move has been started to open a publicity bureau at the club and it is believed that with the proper person at the head of such a bureau, much good can be achieved by the Cincinnati organization.

FARTHEST SOUTH STATE CLUB ORGANIZATION.

Tampa, Fla., Mar. 21—Motor clubs of Florida have formed a State body, a permanent organization of which was effected in Tampa, Fla., on February 24. It will be known as the Florida State Automobile Association, and at present comprises clubs from eight cities. The board of directors are: E. Ed. Bryan and Capt. C. S. Washington, Tampa; G. B. Reynolds, Fort Meyers; W. W. Clark, Bartow; Judge Syd. L. Carter, Gainesville; Albert W. Fisher, St. Petersburg; T. C. Calmes, Plant City; E. L. Lesley, Kissimmee, and J. H. Spencer, Ocala.

MOTORCYCLE CLUBS VERY ACTIVE NOW

Syracuse, N. Y., Mar. 21—The Syracuse Motor Cycle Club has launched a movement with a view of securing the 1910 Federation of American Motorcyclists convention. The president of the Syracuse Club was directed to appoint a committee to invite the Board of Directors of the Federation of American Motorcyclists to designate Syracuse as the meeting place.

SHOW BREVITIES

BAD WEATHER DAMPS ENTHUSIASM AT TERRE HAUTE

Terre Haute, Ind., Mar. 19—Although an artistic success, which gave the people of the town a better idea than before of the importance of the automobile industry, the show which just closed here was a box-office failure, and its promoters are out a considerable sum. The expenses incurred by the management amount to some $500; the decorations and band cost $200, rent $100, and various incidentals not less than $200 more, making a total outlay of $1,000. On the receipts side it appears that 1,430 persons paid to see the show, their contributions amounting to $357.50. The smallness of the attendance is laid to the bad weather which prevailed during show week.

SPOKANE, WASH., SCHEDULES ITS FIRST SHOW

Spokane, Wash., Mar. 19—The first automobile show to be held in this city will open at the Princess Rink next Monday. Two hundred machines will be exhibited and a number of aeroplanes, including one of the Curtiss models from Los Angeles.

PROSPECTS GOOD FOR PASSAGE OF REGISTRATION BILL

Favorable action on the Federal Registration Automobile Bill at an early date is confidently expected by the automobilists of the country as the result of the presentation of the merits of the bill before the delegates in Washington at the recent legislative convention of the American Automobile Association. The encouraging feature in this respect is due to the keen interest shown in the bill by the members of the Committee on Interstate and Foreign Commerce, before whom the hearing was held on the last day of the convention.

As expressing the sentiment of the delegates attending the recent legislative convention, among whom were representatives of Governors from States extending from the Atlantic to the Pacific and from the Gulf of Mexico to the Great Lakes, a resolution was unanimously adopted advocating the passage of the Federal Registration Bill. The resolution follows:

"Whereas, the bill providing for, federal registration of motor vehicles, known as H. R. 5,176, introduced by William W. Cocks, of New York, and now pending before the Committee on Interstate and Foreign Commerce of the House of Representatives, meets the approval of all who have given the matter careful consideration, and the prompt enactment of such a law is necessary for the unhampered development of interstate commerce and travel by means of motor vehicles;

"And since it is only through federal legislation that the unjust and unwarranted burdens now imposed upon such interstate commerce and travel can be removed;

"Now, therefore, be it resolved, That the National Legislative Convention of the American Automobile Association, held in Washington, D. C., on February 15-17, 1910, does urge the speedy passage of this measure, and pledges itself to use every honorable effort to accomplish its enactment."

One of the strongest supporters of the Federal Registration Automobile Bill is Representative William G. Brantley, of Georgia. "The time will come, I predict," he said, "when Congress will be compelled to take hold of the interstate commerce of automobiles and regulate and protect it. Whatever appeal you make to Congress should be predicated upon the right of Congress not only to protect and regulate, but also to restrain and properly control the growing commerce of the country."

Senator Chauncey M. Depew, of New York, who delivered one of the strongest addresses at the convention, cited the fact that ten years ago there were but seven hundred cars in use in the United States, while now the number is three hundred and fifty thousand, aggregating in value $419,000,000.

ROAD BUILDING NEWS

PENNSYLVANIA HOTEL KEEPERS WANT BETTER ROADS

STROUDSBURG, PA., Mar. 21—The annual meeting of the Monroe County Mountain Resort Association, held here recently, was marked by a mass meeting held in the Court House in the interest of good roads. The session was attended by men interested in the resorts, as well as business men of New York and Philadelphia.

W. P. Colton, of New York, was the chairman of the meeting, and the principal addresses were delivered by J. H. Weeks, the head of the Delaware County Automobile Association; E. N. Clark, of the Scranton Automobile Association, and A. B. Dunning, of the same city, a civil engineer; W. C. Freeman, of New York, and Benjamin Butterworth, of Brooklyn. All the speakers impressed upon the minds of the audience the importance of good roads to the summer resort business. The annual banquet was held at the Indian Queen this evening.

The hotels of the Water Gap district, like those in many other parts of the country, are feeling the benefits of the growth of automobile touring.

THE LAW AND THE AUTOMOBILE

NATIONAL GRANGE URGES ENACTMENT OF FEDERAL BILL

One of the strongest arguments in favor of the Federal Registration Bill was made by ex-Governor N. J. Bachelder, of New Hampshire, and Master of the National Grange, with its membership of upward of a million farmers. Governor Bachelder also looks at the purposes and benefits of the bill from the broad viewpoint of the farmer, and he stated at the legislative convention that, while regarding the automobile as an important factor in bringing into the State residents of other places who desire to purchase farms and make their summer homes there, it is also necessary to consider that proper means of travel must be offered.

"The experience of the past six or seven years has shown that different laws on this subject have resulted in many complications tending to discourage even the orderly use of the automobile," he stated. "In some States the natural resentment against the dangerous rate of speed at which automobiles were being operated has resulted in the enactment of unreasonable laws, which defeated their purpose by imposing regulations so stringent that they could not be enforced. And a law that is not enforced is worse than no law at all. For instance, many residents in New York City live for four or five months of the year in the State of Maine. The pleasantest method of reaching their Summer homes is by an automobile trip through Connecticut, Massachusetts and New Hampshire. As travel of this kind is clearly interstate commerce, they can properly claim the right to go through these various States without being forced to pay taxes for the privilege of passing over the roads. I understand that the Supreme Court of the United States has decided that the imposition by a State of taxes on a traveling salesman coming from other States is unconstitutional, and it would seem that if they cannot tax citizens of other States doing business temporarily within its borders it has no right to tax them while merely passing through its territory."

IMPORTANT LICENSE DECISION IN OHIO

COLUMBUS, O., Mar. 21—Upon the request of State Registrar of Automobiles Fred H. Caley, Attorney-General U. G. Denman of Ohio has rendered several decisions of great importance to auto owners. The first question submitted was whether or not a license and set of number plates can be transferred from one owner to another upon the sale of a motor vehicle. After analyzing the law, the Attorney-General comes to the conclusion that such cannot be done legally. He quoted the laws as follows: "Every owner of a motor vehicle acquired during any year shall, immediately upon acquiring such motor vehicle, file an application with the necessary fee for registering the motor car." He says no exception is made to allow the license to be transferred with the car.

Upon the question of using the same set of number plates on different cars by one owner, the Attorney-General says that it is unlawful for a person selling a motor vehicle to transfer the tags to a new motor vehicle purchased by him.

The Attorney-General also rendered an opinion in which it is held that all motor vehicles excepting fire engines and ambulances have to be registered, notwithstanding the ownership.

Aeroplane Weight and Power

Editor THE AUTOMOBILE:

[2,197]—Please answer these questions through "Letters Interesting and Instructive":

1. What is the smallest wing surface of an aeroplane that will lift two hundred pounds?

2. Would it require a high or low powered motor to lift this weight?

3. Where is the elevating rudder located on the Blériot monoplane? LESLIE M. SANEDER.

Denison, Kan.

There is a considerable variation in the surface required, depending on the shape of the surface. A relatively flat surface will support less weight than a more curved one, but, weight for weight, requires less power. The Wright machine, the surfaces of which have a curvature of but one in 20, carries only two pounds to the square foot, but does so with one horsepower to every 41 pounds. The cross-channel type of Blériot. with a surface curvature of one in 12, carries 4.5 pounds to the square foot with one horsepower to every 29 pounds. The Wright machine can average 40 miles an hour to 36 for the Blériot (all figures relate to the Blériot fitted with the three-cylinder 25-horsepower Anzani motor). Thus you can suit yourself in both ways; you can either have a small high-powered machine, or a large, low-powered one to carry the same weight.

The Blériot monoplane has its elevating rudder in the rear, its front edge being about 8½ feet from the rear edge of the main surfaces. There are really two rudders, one on each side of a stationary surface, but acting in unison.

The 1910 model Blériot, known as type 11 *bis*, is said to carry 6½ pounds to the square foot, being both smaller and heavier than the 1909 model.

Licensed and Unlicensed Cars

Editor THE AUTOMOBILE:

[2,198]—Will you kindy tell me through the columns of your esteemed paper what A. L. A. M. means, and what its connection with the Selden patent is? Notice that there is considerable discussion on this question now, also that parties purchasing unlicensed cars are liable to suit. As I am contemplating the purchase of a car, I would like this information for personal protection.

Fond du Lac, Wis. A. W. BISSETT.

The initials A. L. A. M. are but an abbreviation or shortening of the full and very long name of the association, which comprises all of the makers authorized under the Selden patent to make and sell cars, the full name being Association of Licensed Automobile Manufacturers. This association does not actually own the patent, that being the property, either wholly or the controlling part, of the stockholders of the old Electric Vehicle Company, Hartford, Conn., but the association decides by vote which among the applicants for membership shall be given such membership, the same election being subject to the approval of the aforementioned owners.

As far as a suit is concerned, it has been laid down as the policy of the association and the patent owners, not to take such a course, at least not until the patent is definitely and finally upheld by the higher courts. This is a matter which will doubtless carry over until 1911, for certain, and possibly until 1912, in which latter year the patent expires.

Parts for Discontinued Cars

Editor THE AUTOMOBILE:

[2,199]—Can you advise me through "Letters" where I can get Queen automobile parts, knowing that the Blomstrom concern is now out of business. I need some parts for my transmission and so must find the party who has the patterns and makes the parts.

Marysville, O. L. HENDERSON.

Parts for these cars may be obtained from the Auto Parts Manufacturing Company, located at St. Antoine street and Michigan Central Railway, Detroit, Mich. This firm not only make and sell the parts for the Queen cars, so they inform us, but also for the Northern and Wayne cars, neither of which are now regularly manufactured.

LETTERS INTERESTING

Simple and Efficient Still

Editor THE AUTOMOBILE:

[2,200]—I am a subscriber to your valuable journal and have recently become deeply interested in the prevention of radiator inefficiency due to the incrustation of the various mineral salts suspended in the water used. Will you kindly give a sketch of a simple and cheap still such as may be made by the local tinsmith, since the use of distilled water seems to be the only absolute way of preventing incrustation. "An ounce of prevention is worth a pound of cure," so they say. P. L. MORGAN.

North Ridgeville, O.

This is an excellent plan, and the simplest still that can be suggested is made from an old tea kettle, rubber tubing. two long glass tubes of different diameters, one large, one small and more rubber tubing. As this apparatus is so simple that any one can buy the materials, assemble them, and then have the use of perfectly pure water, it will be described in detail.

First buy from the drug store a length of rubber tubing of rather thick walls, large enough inside to go over the spout of the tea kettle which you intend to use and long enough to lead from the tea kettle situated over the fire to a source of cold water, which, if the kitchen be utilized, will be the kitchen sink. Then buy a small diameter glass tube. which will fit one end of the rubber tube very tightly.

Next buy another and much larger glass tube, say, 1 1-2 in. inside diameter, but about an inch shorter, the first one being about 18 in. long. Finally you will need another short length of rubber tubing of the same size, not over two feet long.

Put the tea kettle on the store, attach the long rubber tube, leading it over to the source of water, then slip the larger tube over it, and manage to hold it in that place by some means so that the cold water from the faucet can run in the upper or open end of the large tube. Hang the combination of the two tubes one within the other so that both are slightly inclined. The object of the inclination is to permit the cooling water to flow around the inner tube and then out to the sink drain. This flowing cold water will condense the steam in the inner tube, which will then flow through the shorter rubber tube (attached to the other end) to some convenient receptacle.

The process will then proceed as follows: Water put into the tea kettle will be converted into a vapor, steam, leaving the impurities behind in the tea kettle. This vapor will pass through the long tube to the glass, when the cold water flowing around the outside will condense it to a liquid again, which will then flow through the shorter rubber tube to the receptacle. Using as large a tea kettle as possible, and carefully bottling the resulting pure water in bottles with ground-glass stoppers, which have previously been scalded out clean, will result in giving you a source of pure water which can be used without fear of trouble from incrustation.

A more elaborate still may, of course, be made, but at some expense. This, however, would present many features which would be worth the money expended to motorists able to spend that amount, so that a drawing of one will be presented at an early date.

A variation of this idea, to dispense with the breakable glass tubes, would be to get enough rubber tubing not only to lead to the sink but also to form several coils around the bottom of a tub or dishpan. The tubing would then be in one piece, with one end connected to the spout of the tea kettle and the other connecting with the receptacle for the distilled water.

ANSWERED AND DISCUSSED

Starting on the Spark

Editor THE AUTOMOBILE:

[2,201]—To settle an argument, will you kindly tell me if a car will not start off the switch; is it because the cylinders do not hold compression? A manufacturer here states that compression has little to do with it, as he says that he has taken out his spark plugs, looked at them, replaced them, and then started on the switch. I was under the impression that the gas would escape as soon as the spark plug was loosened, or if the valves did not shut closely. He says that only the extra quantity that is compressed will, because, as gasoline vapor is heavier than air, enough to fill the cylinder will remain there, but he states if the mixture is not proper when the gas is not compressed one cannot get the explosion, whereas if the mixture is correct one gets explosion enough to turn over the engine on the spark taking place, although there is no compression whatever. Is he correct in this? If he is, does one need a rich mixture or a poor one? AMATEUR.

Toronto.

Your information is somewhat misleading, for while a correct mixture is a necessity for starting purposes, and an explosion of such a mixture may be produced when it is not compressed, this latter occurrence is so rare as to be almost negligible. In fact, a more truthful statement would be that compression is absolutely necessary, so that the writer of the above letter is more nearly right than his informer.

Starting on the spark depends upon the retention of the compression. from the fact that the spark obtained under stationary conditions is fairly weak, and as such would not ignite a partly compressed mixture, or one not compressed at all. More than this, it is a pretty safe statement that the rich mixture is easier to ignite than the weak, and that compression leaks would result in a comparatively weaker mixture, so that from that viewpoint the mixture not compressed would also be more difficult to explode.

It is doubtful if the experiment spoken of, in which the spark plugs and other parts were removed from the cylinder, leaving them open to the atmosphere, and that then, after replacement. the engine was started on the remaining mixture, on the spark. ever happened, or could be made to happen.

Names and Makers of Carburetors

Editor THE AUTOMOBILE:

[2,202]—In the issue of January 6, 1910, I notice, under the head of "Things That Attract in the Accessory Field," and under the sub-head "Carbureters Show Encouraging Improvement," a mention of a device for mechanical atomization in one carbureter, and a needle valve construction in another for the same purpose. The names and manufacturers of the carbureters are not given. Will you please give me their names, as I desire to get their catalogs or descriptive matter. H. CASSEDY.

Brookhaven, Mass.

The device for mechanical atomization you refer to we believe is the "Homo," although this is not a carbureter, but is intended to be placed in the inlet pipe between the carbureter and the motor. It is made by the Gasoline Motor Efficiency Company, ersey City, N. J. The other carbureter referred to is doubtless the Breeze, made by the Breeze Carbureter Company, also of Jersey City, N. J.

There are a number of devices which nearly fit the descriptions given, so that an exact selection is nearly out of the question. It is hoped that the writer of the above letter will bear this in mind when reading the above letter.

Can One Vibrator Do Work of Four?

Editor THE AUTOMOBILE:

[2,203]—I have an old four-cylinder, four-cycle car with a four-unit coil and dry batteries. When the vibrators are set right the motor runs very well, but after the car has gone a few miles some of the vibrators lag, the engine fires unevenly and the vibrators have to be adjusted. I have read about the master vibrator, and the theory of it seems right, as synchronism is very important, but I cannot understand how one vibrator can do the work of four when four cause so much trouble. Are master vibrators as successful as the makers claim? I have also read of the benefits of the Atwater-Kent "Unisparker," which does away entirely wtih vibrators. Is it a fact, as they claim, that one spark fires a charge as effectively as a series of sparks, as in a vibrating coil? Do you think either of the above methods would cure my trouble? T. W. M.

Little Ferry, N. J.

The first description of your trouble sounds very much like that old bugbear, weak batteries. Are you sure that a new set would not put your engine right again, without considering any further changes.

Master vibrators are very satisfactory in service. There is no trouble about making the one vibrator work overtime, as when four are used each one is working less than one-fourth of the time. If you were employing four men who only worked two hours a day each, you wouldn't hesitate long in replacing them by one man who would work eight hours.

The theory of the Atwater-Kent device is correct, as one spark is sufficient to fire the mixture under proper conditions. With a series of sparks, if the first one does not come at the right time, or fails to ignite the mixture, the result is practically a misfire; for even if the others of the series do succeed in causing an explosion, it will not be of sufficient strength to assist in running the engine.

There is no reason why your engine should not be made to give satisfactory service with its present ignition system, but either of the two devices would save your battery consumption.

Materials for Garage Floors

Editor THE AUTOMOBILE:

[2,204]—Will you please tell me what is the objection, if any, to a garage floor being of paving brick? Isn't it (brick) less liable to absorb and show oil and other spots than a concrete floor? Also, how is it best to lay them? CLAYTON.

Oshkosh, Wis.

Not only is there no objection to the use of paving bricks for garage floors, but their use is an excellent thing. The bricks will not, as the letter above brings out, absorb moisture, oil, grease, nor anything else liable to be on the garage floor, but moreover, has the big advantage of being readily and quickly laid by anyone, while cement, although easy to lay, is dodged by the ordinary amateur workman as a dirty if not complicated job.

The best way is to lay them on edge, but this has a disadvantage, where cost is the prime consideration, of nearly doubling the initial cost of the bricks. The best way would be to lay them on a deep bed of sand, and bond with cement, although tar may be used as a bond, or the bricks may even be laid up loose, without any bond, and later on a thin grout of cement or tar or other material poured in between them.

Graphite Used in Care of Tires

Editor THE AUTOMOBILE:

[2,205]—In your reply to No. 2,141, Letters Interesting and Instructive. you advise painting the inside of the tire shoe and the outside of the tube with graphite. Kindly state how to prepare graphite paint for this purpose. G. L. STAYMAN.

Indianapolis.

"Painting with graphite" seems to have been a misleading term. Of course none of the ordinary oils used for paint bodies would be suitable for this purpose, as they would rot the rubber. What was meant was that the graphite should be applied in its powder form, either by dusting it on or using a brush. French chalk is also used for the same purpose.

Accessories

Traction is just as much of a problem in connection with large trucks and wide solid tires as it is when reference is had to touring cars and pneumatic tires. The tractive ability, while it varies somewhat with the nature of the tire equipment, is very largely dependent upon the weight resting upon the wheel and the character of the roadbed. The weight multiplied by the coefficient of friction represents the situation in the main, and non-skid devices are utilized to increase the friction. Fig. A, shows a scheme as it was applied to a Packard truck, which embodies the use of a substantial chain around the girth of the wheel, placed between the two tire members and substantially flush. A series of equidistant laterally disposed bars, with eyes which engage the chain links, are responsible for the good work done. This system is known as the Paragon chain, and was exhibited on Packard trucks during recent shows by F. H. Scranton, Thoroughfare Building, Broadway, New York City.

There always has been a certain amount of danger to the inexperienced autoist who disregards instructions and assumes a clumsy attitude when cranking a motor. Sometimes the back kicks which are experienced are due to a derangement in the timing system, or to the absent-mindedness of the autoist who attempts to crank on an advanced spark. Even if the spark is properly retarded, it is perfectly possible to have trouble of this sort, provided the autoist fails to vigorously spin the crank. This trouble will be the more noticeable in motors with a high compression, especially after they have been heated up, and if lazy methods of cranking are indulged in. It is on this account that inventors have undertaken to supply a means which will serve for the purpose and protect the autoist during the process. Fig. B shows just such a device, which was exhibited at Detroit by J. Franklin Wilkinson, and is designated as a mechanical motor starter. It is

(Continued on page 616.)

Making a Demonstration

(A) Inter-State "40" touring car being tried out by C. S. Welch, sales manager of the company, with C. E. Easton, advertising manager, in the other seat. This car is shown with lamps, generator, folding glass front, and everything complete as required by an autoist for efficient work. The body represents a distinctly Inter-State innovation which is growing in popularity. The 4-cylinder water-cooled motor has cylinders with a bore of 4½ inches and 5-inch stroke, a cellular radiator aided by a centrifugal pump is responsible for cooling, and a U & H magneto, with a coil and dry cells in the auxiliary position is assurance for proper ignition work. Lubrication involves the use of a pump, and a multiple disc clutch has 63 members, thus presenting an unusually large area of surface. The transmission is a three-speed selective, to a shaft drive, and the wheelbase is 118 inches. This car weighs 2700 pounds, has 34 x 4 tires all around, and sells for $1,750. The Inter-State Automobile Company, Muncie, Ind., maker, reports an easy market for this car, and excellent progress in the process of manufacture.

(B) The latest Franklin innovation is shown in Fig. B, which represents a Franklin model fitted out with a glass bonnet, so that during demonstration by the company's representative intending purchasers are enabled to observe the workings of the new Franklin air-cooling system, which is so contrived that the cooling air is definitely measured out for each of the respective cylinders, thus eliminating all differences in cooling as between them. The idea attracts attention because of its novelty, but there is a certain underlying virtue attached to the plan, and those who are but little skilled in a mechanical way, are enabled to more clearly understand the underlying principles of the Franklin design. The H. H. Franklin Mfg. Co., with its large plant at Syracuse, N. Y., is having excellent success with both its 4 and 6-cyl-

WHAT THE SELDEN PATENT DECISION DECIDED

SCOPE OF THE DECISION AND ITS OPERATION

By Xenophon P. Huddy, LL.D.

IT is familiar history that Judge Hough of the United States Circuit Court for the Southern District of New York upheld what is known as the Selden Patent after a bitter legal controversy which was waged for years. Although this decision is not final and an appeal has been taken from it, still it is of the greatest interest and importance to the automobile industry and users of motor vehicles. If the appeal fails, Judge Hough's decision stands and it should be borne in mind that the burden rests upon the appellant, the defeated party, to show that the decision against him is illegal and ought not to stand. The appellant in this case has the onus and the burden of upsetting that which the lower court decided. He who asserts that a wrong or an error has been committed, has the affirmative upon his shoulders. So it may be said that the first point of advantage gained by the Electric Vehicle Company by the decision referred to was, to place the burden on the defendant to show that the Selden Patent is invalid and Judge Hough's decision sustaining it, is erroneous. This decision is officially reported and may be found under the title Electric Vehicle Co., et al. vs. C. A. Duerr & Co. et al., in volume 172 Federal Reporter at p. 923. The actual questions decided by the Court are as follows:

WHAT THE DECISION HELD

"The Selden Patent, No. 549,160, for a road locomotive, granted in 1879, claims 1, 2 and 3 are all for combinations the elements of which were all old in some form, although changed, modified, and co-ordained by the patentee to adopt them for harmonious action in such combinations, especially the "liquid hydrocarbon gas engine of the compression type," which constitutes the motive power and is the most important feature. At the time of the filing of the application, the art to which it relates, that of a self-propelled road vehicle with a considerable radius of action over ordinary highways and capable of management by a single driver, and he not necessarily a skilled engineer, had no practical existence, and the patent, which embodies all the parts of an operative vehicle of that kind, discloses invention of a primary character. As so constructed, claims 1, 2 and 3 are infringed by the Ford machine, and claim 1 and 5 by the Panhard French machine."

COMMENTS ON THE DECISION

The above is set out verbatim as it appears in the law report so that the reader may properly understand the specific points passed upon by the Court. From the many newspaper accounts of the decision written by laymen, it is quite possible that the automobile public may have received mistaken impressions. The decision and the opinion of the Court have been commented on extensively throughout the United States and Europe. The legal periodicals have also discussed the decision as appears in the editorial reprinted in this number from "Case and Comment." The author of this editorial is asserting broad propositions in apparently disagreeing with Judge Hough. Of course, almost every case has two sides before it is passed upon by a competent Court and even if a judicial decision is rendered, enough lawyers can be found who will disagree with the Court's judgment, since it is a part of the legal profession to disagree. No doubt one might be able to find a lawyer in this wide land who would disagree to any proposition of law that any court had decided against; so we should, before giving much weight to an argument against a decision, such as referred to above, examine and dissect the argument and the decision, compare the two and ascertain the truth or falsity of the premises upon which the dissenter's contentions are based.

WHAT ARE INVENTIONS

Of course, the subject matter of the patent must be *new* and *useful* and must have called for the exercise of the inventive or creative faculties of the originator. The article must be new whether the invention is an entire machine or an improvement on a machine, but the invention may consist of a combination of mechanical powers. This is the nut-shell of the Selden Patent decision. Notwithstanding the fact that old and well-known appliances were used, the Court says:

NEW USE OF BRAYTON'S ENGINE

"With Brayton's engine in mind, he [Selden] organized a new road vehicle. To be sure, he did substitute one old and well known prime mover (gas) for another (steam), but in so doing he devised and used an arrangement of Brayton's engine never before attempted, one that Brayton never suggested, made or patented, and without which the road vehicle was an impossibility. This mental concept constituted invention if capable of redrction to operation."

In conclusion it may be said that since the United States Circuit Court has found as a matter of fact and law that Selden's claims constituted an *invention*, even though admittedly composed of some old and well-known parts, and since the patent has been sustained and declared valid, it will be a difficult task for the defendants to overthrow the Court's decision by claiming to the contrary.

It will be noted that the point of this Selden Patent case is that the combination discloses invention of a primary character according to the language used by Judge Hough. It might be stated that Judge Hough is a man of learning in patent law and fully capable of handling all questions presented by the litigation, quite as much so as the writer of the editorial before referred to. Judge Hough is a lawyer of profound learning and his decisions have been uniformly upheld by the United States Appellate Courts.

SELDEN PATENT COURT DECISION ON NEW GROUNDS*

A NEW departure seems to have been taken in upholding the Selden patent on automobiles. The court says that no litigation closely resembling the case has been shown to it, and it cites no authority for its holding, so that it seems that the court itself recognizes that it is treading on new ground. The claim of the patent is for the "combination with a road locomotive provided with suitable running gear, including a propelling wheel and steering mechanism, of a liquid hydrocarbon gas engine of the compression type, comprising one or more power cylinders, a suitable liquid fuel receptacle, a power shaft connected with, and arranged to run faster than, the propelling wheel, an intermediate clutch or disconnecting device, and a suitable carriage body adapted to the conveyance of persons or goods, substantially as described." This, of course, is a mere claim for combination of several parts, all of which were old at the time, and it would seem that, if any patent for it could be

* Courtesy of "Case and Comment," published by the Lawyers Co-Operative Publishing Co., Rochester, N. Y.

sustained, then any application of power to the operation of any machine is subject to patent. In fact, although the claim is for a combination, when changed in form and reduced to its ultimate terms, it is merely a claim for the application of power in the shape of a gas engine to the running of a road vehicle. Such a claim has never been thought to be patentable. In fact, the court says, in referring to a machine manufactured by Rosenwald, that, even if it had been successful, he might, nevertheless, have found his patent invalid by American law, because each part of his vehicle was doing just what it had always done without any new "co-operative law," while his engine, in particular, was the same motor which, before it was applied to his brougham, had, perchance, driven a lathe, and might to-morrow do something else. On the face of Selden's claim, that is precisely what he did, and that would make his patent unsustainable. The court says that there is no denial that, in form, nothing but combination was claimed. But then comes the point of the decision, which seems to be in advance of the former law.

The court says that Selden's combination cannot be taken apart and each element recognized as something that had done the same thing or series of things before. It then proceeds to show that he took the old Brayton engine and made some alterations in it. He built a plurality of cylinders to minimize the necessity for a flywheel; he produced an inclosed crankcase, and used a small piston with a short stroke. By so doing, he devised and used an arrangement of Brayton's engine never before attempted —one that Brayton himself never suggested, made, or patented, and without which the road vehicle was an impossibility. So that, in 1879, when Selden applied for his patent, there was not one gas engine, which, in its then form, could be made an element in a road wagon combination. The court further says Selden solved this difficulty, and such solution gave him the right to claim broadly the thing which was the leading element in his invention when used in his combination. But he did not claim it. What he had invented was an improvement on the gas engine, but there is nowhere in his claim any mention of such improvement. What he claims is the combination, and that alone; and, so far as appears from his papers, the elements of his combination were all old and well-known. There is no suggestion that he had made an improved engine, and sought a patent on that, and the question then arises whether one can invent a part of a combination, and then, without mentioning or claiming his invention, simply make it an element of his combination, treating it as an old device, and when he secures a patent on his combination, shut others out of the use of the device which he has not claimed Such does not seem to have been understood to be the law; and, from the fact that no precedents could be found, the holding that it can be done would seem to be a new departure in patent law If the engine was in fact the old, well-known engine, the court itself, as above shown, says that the combination would be invalid. Does the fact that the engine was in fact new alter the case when Selden treats it as old, and makes no claim for it? Prima facie it would seem that, by reason of the fact that he abandoned his claim on it, so that it at once became public property, it would fall under the well-established rule which applies in any case of a mere aplication of power to the operation of machinery. From the opinion, the question of the sufficiency of the claim to cover this invention does not seem to have been considered by counsel, but they seem to have confined their attention to the question of fact whether or not Selden had a practicable working model when his application was filed, and whether or not defendant's machines infringed the patent. It is understood that the case will be appealed, and the question of the possibility of excluding the public from the use of a new device by simply claiming it as part of a combination may be presented to the consideration of the appellate court. If the device can be covered in that way, an interesting question arises as to the scope of the patent. The adaptation of the gas engine used by Selden in his automobile is practically the same as that used in motor boats, aeroplanes, and for other purposes; and, if that is Selden's invention, the question arises, Can he recover royalty for the use of it in all ways in which it is now used?

JERSEY AUTO BILLS VIGOROUSLY OPPOSED

DESPITE the fact that the Edge bill was defeated in the New Jersey Legislature, two more bills were introduced and it looks as if the autoists of the state will have to exercise their fighting ability before the end of the legislative term. The Edge bill, which suffered defeat, was to allow motorists registered in other States to tour New Jersey without further formality. The bill was expected to become a law, but it did not meet with the approval of Senator Joseph S. Frelinghuysen, President of the Senate, whose influence was sufficient to beat it.

One of the two bills which subsequently were introduced provides for an increase in the license fees of automobiles, and contains a joker which will do away with the present limited tourist privilege permitting non-resident motorists registered in their home States to tour New Jersey for eight days in any one year upon the payment of $1.

The second bill allows the State of New Jersey to pay one-half of the cost of the proposed new ocean boulevard, instead of the quarter of the expense of the construction of new roads, which the State usually bears, and also permits the funds in the State Treasury accrued from the licensing of automobiles to be applied to the maintenance of the boulevard, instead of dividing such funds pro rata among the counties.

Both bills, which are favored by Senator Frelinghuysen, are strongly opposed by the automobile interests of the State.

Resolutions attacking both measures have been passed by the leading automobile organizations of the State, the New Jersey Automobile and Motor Club of Newark, N. J., which has a membership of more than 2,000; the Associated Automobile Clubs of New Jersey, a federation of the clubs in New Jersey; the Automobile Club of Hudson County, with headquarters in Jersey City, and the North Jersey Automobile Club of Paterson, N. J.

The North Jersey Automobile Club held a special meeting recently and passed this resolution:

Whereas, Senate bill No. 215 provides for the diversion of money received for licenses of automobiles to other purposes than those named in the original bill covering licensing of automobiles as adopted in April, 1906, together with certain amendments added in 1909, and

Whereas, A Senate bill provides for increasing the license fees covering all automobiles above 15 horsepower; be it therefore

Resolved, That the North Jersey Automobile Club in special meeting assembled protest most vigorously against the passage of either or both of these bills and ask that the members and legislators for Passaic County and the State Senator representing this district not only to vote against these bills personally, but to use every honorable endeavor to influence other members of the Senate and Assembly to vote against their passage.

The members of the club also pledged themselves to work against any candidate for public office who votes for either of the two bills imposing added taxation on automobiles.

INTERESTING NEW JERSEY DECISION

An extremely interesting case on the question of the constitutionality of the New Jersey motor statute which requires a license from both cars and drivers is found in Cleary vs. Johnston, 74 Atl., New Jersey, 538. The complaint was that R. H. Johnston drove a motor car in the streets of Trenton, N. J., without having his motor car licensed and registered according to the law of New Jersey, and without having paid his registration fee.

The court held that the statute, which required registration by both resident and non-resident owners, was constitutional, and that the fine of $100 assessed must be paid.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

As the weather clears up and the roads become hard, a new gathering of autoists will start out; all will go in search of enjoyment, some for the sake of health, and of experience; it lies before them. Just how many inexperienced purchasers of automobiles there will be numbered in the aggregate, it is difficult to state. If statistics have any foundation, 100,000 is a low figure to fix upon. Of this number, if but one per cent. proves to be totally incompetent, the daily papers will have at their disposal subject-matter for 1,000 double head lines, and it may be that some of the columns of matter will contain nuggets.

It is a serious subject, this, and it offers wide opportunity for reflection. Those who fail to appreciate the improvements wrought in automobiles within a few short years will only remember the time when brakes were poor, steering equipment insecure, and the men at the wheel were ill-fitted to the task. They may have failed to take into account the subconscious automatism of the whole situation; brakes are now capable, steering equipment is reliable, and the whole populace has undergone a change. Men who do not profess mechanical knowledge seem to understand more about automobiles to-day than designers did yesterday.

It is fortunate that capability keeps stride with requirement; the leader barely outnecks the flock; the whole world advances in unison and yet there is the hindmost. It is the tail end of the procession which must be watched, and it matters not whether it is in an army, a fleet of battleships, or, instead, the users of automobiles.

That the tailenders are likely to come from the midst of he 100,000 who just purchased their first automobile, is a fair inference, and that they will be vigilant and prudent it is hoped. If they are unable to appreciate the extent of the hazard which attends blind and reckless driving; if it is not in their nature to allow for the safety of others, they will most likely belong to the class called selfish, and it may be possible to reason with them through their pocketbook.

The life of an automobile will be long, or short, depending merely upon the speed at which it is driven, and to a large extent quite independent of the quality of material of which it is made, or the accuracy of workmanship expended upon it. If the speed is 40 miles per hour, the depreciation will be four times as much as when the speed is 20 miles per hour. If, in turning a corner, the speed is excessive, the structural parts will then be subjected to enormous stresses relative to the work the parts will have to do at a high speed on a straightaway.

There is one other point which is a forceful argument to a pocketbook. No automobile, however well made (no matter how good the brakes may be) may be stopped within a certain distance, and this length is fixed by the speed and weight of the car, considering the adhesion of the traction (road) wheels.

An accident is a mathematical certainty if a car is driven at a speed so high that (considering the stopping distance allowed, in a given case) it fails to conform to the set conditions. An inexperienced autoist must learn what the stopping distance is for his particular automobile, and when he accomplishes this task he will then have to learn to judge of distance. When a new autoist becomes proficient in these important respects, he may then graduate into one of two classes, i. e., a prudent and respected citizen who knows it is ill-advised to exceed a reasonable and safe speed considering the surrounding conditions, and the man who, feeling his skill, takes the long chance.

The several legislative bodies throughout the country are now busying themselves with legislative matters involving the automobile. In some States there are several bills pending, each one of which differs from the other in principle and detail. The sponsors for these bills, severally, stoutly maintain for their respective efforts that they are just what should be imposed upon the users of automobiles, and since each one of the bills differs radically from the other it is a self-evident fact that nearly all of them must be wrong in principle and in detail.

All that can be done by the autoists throughout the country is to oppose these half-baked efforts and go in for conservative and proper legislation, making sure that the laws will be of a character which will put reasonable restrain upon reckless drivers, whether or not they pilot a brewery wagon drawn by horses, a big touring car with the owner at the wheel, or a chauffeur who may indulge in a ride on his own account. Traffic regulations and road laws are just as necessary to-day as they ever were, but the wild talk which is heard by citizens who lack experience, keenness of observation and fairmindedness is not a sufficient foundation upon which to rest these regulations and laws. In the long run it is believed that sound reason will prevail, and all that autoists have to do is, have patience, be vigilant and vote tight.

Indianapolis Is Now Holding Opening Week

INDIANAPOLIS, IND., March 22—Local tradesmen are enjoying their annual opening week, which will close Saturday evening with a banquet at the Denison Hotel, when covers will be laid for four hundred guests. Charles A. Bookwalter, former mayor, will be toastmaster at the banquet and other speakers will include Gov. Thomas R. Marshall and Edgar Apperson.

The affair is under the auspices of the Indianapolis Automobile Trade Association, which includes fifty-nine manufacturing and retail concerns in its membership. Monday and Tuesday will be devoted to displays in factories and salesrooms. A floral parade is set for Wednesday afternoon, various contests Thursday afternoon, a commercial car parade Friday afternoon, and the banquet Saturday night.

At the banquet a suggestion that the Indiana Automobile Club be revived and reorganized will be made and Carl G. Fisher, president of the Indianapolis Motor Speedway Co., will be mentioned as its new president. The club is affiliated with the A. A. A., but has been inactive for some time.

It is expected that Indianapolis will be much in the limelight this season by reason of the various events scheduled at the speedway. The program for the season is as follows: May 27, 28 and 30, automobile races; June 12-18, aviation meet; July 1, 2 and 4, automobile races; August 12, 13, twenty-four hour automobile race; August 12, local balloon race; September 2, 3 and 5, automobile races; September 17, national championship balloon race, and October 22-26, international aviation flyers. On May 27, the Prest-O-Lite trophy will be contested for in a 100-mile race and on the following day the Wheeler and Schebler trophy will be hung up for a 200-mile event. Last August the Wheeler and Schebler trophy was offered for a 300-mile race which was called off after Lynch, driving a Jackson, had covered 235 miles. It is said that more attention to the manufacture and sale of commercial cars will be paid this season by local manufacturers and dealers in Indianapolis. Notwithstanding the fact that there are probably more commercial cars in use in Indiana than in any other city in the country in proportion to size, it still remains that one or two agencies have practically controlled this class of business—a condition possibly due to the fact that dealers and manufacturers have had all of the pleasure car business they could well handle. With added facilities and more salesmen, however, commercial cars will be made a prominent feature by the local concerns. Ira V. Buckley, Harvey T. Huff and Edmund B. Walker are the directors of the Commercial Car Company organized in Indiana with an authorized capitalization of $100,000. It is said that this company will build a factory for commercial cars exclusively, and that provision will be made to go in on an extensive basis.

Indianapolis dealers, in preparation for the annual show to be held during the week beginning March 28, are adding new agencies, while new companies are being organized. Among them may be mentioned the Co Auto Motor Company, handling the Jackson, Fuller, Stearns and Westcott; the Weber Automobile Company, a new concern, will represent the Apperson; the Fisher Automobile Company has taken on the Courier, while the Conduitt Automobile Company has added the Velie.

Coming Events in the Automobiling World

Mar. 21-26........Spokane, Wash., First Annual Automobile Show, at Princess Rink.

Mar. 21-30........Buffalo, N. Y., Convention Hall, Third Annual Power Boat and Sportsmen's Show, Buffalo, Launch Club. D. H. Lewis, Mgr., 760 Main St.

Mar. 21-28........Denver, Col., Convention Hall, Denver Motor Club's Annual Automobile Show.

Mar. 26-Apr. 2...Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.

Mar. 26-Apr. 2...Montreal Automobile and Motor Boat Show, Official Motor and Sportsmen's Show Committee of the Automobile and Aero Club of Canada, in the Coliseum. E. M. Wilcox, Manager, 123 Bay St., Toronto.

Apr. 6-9..........Watertown, N. Y., Automobile Show, Watertown Automobile Dealers' and Manufacturers' Association, in the State Armory.

Apr. 9-16..........Elmira, N. Y., State Armory, Automobile Show, Elmira Chamber of Commerce.

Apr. 11-16........Harrisburg, Pa., Kelker Bldg., Automobile and Sportsman's Show, Harrisburg Automobile Dealers' Association, B. R. Johnson, Manager.

Apr. 11-16.........Erie, Pa., Meyer Block, Automobile and Motorcycle Show.

Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.

Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.

Jan. 17-24, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.

Feb. 18-25, 1911..Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

Mar. 23-24........Daytona, Fla., Speed Carnival, Florida East Coast Automobile Association.

Mar. 26...........Atlanta, Ga., Hill Climb, Atlanta Journal and Fulton County Automobile Club.

Mar. 28-29........Savannah, Ga., Endurance Run to Jacksonville, Fla., Savannah Automobile Club.

Apr. 8-10 & 13-17.Los Angeles, Cal., Inaugural Meet, Motordrome.

Apr. 30-May 2...Philadelphia, Roadability Run to Atlantic City, Quaker City Motor Club.

May 2............Flag to Flag Endurance Contest, Denver, Col., to City of Mexico.

May 5-7..........Atlanta, Ga., Track Races. Atlanta Automobile Association.

June 11..........Wilkesbarre, Pa., Annual Hill Climb Up Giants' Despair, Wilkesbarre Automobile Club.

Foreign Shows and Races

Mar. 19-Apr. 3...Berlin Automobile Show.
Mar. 22..........Elegance Competition at Monte Carlo.
Mar. 27-Apr. 4...Prague, Austria-Hungary, Automobile Show.
Mar. 28..........Brooklands, England, Easter Meeting.
Mar. 31-Apr. 3...French Spring Wheel Competition.
Apr. 2-24.........Turin, Italy, Automobile Show.
Apr. 27-28........Brooklands, England, Two-Day Meeting.
May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.
May 28-June 9...St. Petersburg, Russia, Automobile Exhibition.
June 2-8.........Prince Henry (German) Touring Competition.
June 13-18........Scotland, Scottish Reliability Trials
June 20...........French Voiturette Race.
June 21...........French Stock-Car Race.
June 22-July 5....Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.
June 27...........Speed Trials at Kiev, Russia.
July 12-18........Ostend, Belgium, Automobile Week.
July 20-25........Boulogne, France, Automobile Week.
Aug. 1-15.........Ardennes, France, Meeting.
Aug. 15-Sept. 15..French Industrial Vehicle Trials.
Aug. 21...........Salon, France, One and Five Kilometer Trials.
Aug. 28...........Mont Ventoux, France, Hill Climb.
Sept. 3-6.........Liedekerke, Ostend and Voiturette Cups, at Ostend.

AUTOS PERMITTED IN OBERAMMERGAU

Passion Play committee is building a garage to accommodate 200 automobiles during the Passion Play and as a special concession to Americans automobiles will be permitted in Oberammergau during the season of the Passion Play, which is from May to October, according to advices received to-day by the North German Lloyd Company, the official representatives of the Passion Play committee in the United States.

Many persons who contemplate visiting the Passion Play during this year were much worried because of the ordinance of Oberammergau forbidding the use of power cars in the village territory. Repreesntations were made to the Passion Play committee on behalf of the Americans who wanted to take their automobiles with them and as a result the ordinance has been rescinded during May, June, July, August and September of this year.

In order properly to care for the automobilists who visit Oberammergau, the Passion Play committee has built a fireproof garage with accommodations for 200 cars and their attendants.

Contracts have been made with a leading firm to keep the roads free from dust by the use of oil or some other binding material.

Visitors will have a variety of choices in which to reach the Passion Play. Already arrangements have been made for a dirigible balloon to make daily trips between Munich and Oberammergau, while those who do not care for the balloon route may go by automobile, train and trolley, train and stage coach or may drive there from Munich, a distance of 43 miles.

BILLINGS & SPENCER GOING TO MIGRATE

Hartford, Conn., March 22—The drop-forging plant of the Billings & Spencer Company of this city will be removed to Dividend in the town of Rocky Hill as soon as the transfer can possibly be made. New buildings will be erected at the new site just as fast as the work can be done. This action was taken at a special meeting of the board of directors. The cause of the removal of the drop forging department to the down-river town is unique. That is to say the present plant is located in a neighborhood thick with dwelling houses and it was feared that the residents would not tolerate the operation of the drop shop 24 hours a day, which is necessary under the present busy conditions. The residents of Rocky Hill in which the town of Dividend is located are quite anxious to get the drop shop in that town and it was voted by the town that if the plant was located there a new highway will be constructed down to the site of the factory and further agreed that if possible the annual tax on the plant is not to exceed $500. The new shop of the Billings & Spencer Company is to be 150 x 70 feet. A dock will be constructed along the Connecticut River and there are also other facilities for shipment of the company's product by rail. This move does not affect any other department of the Billings & Spencer Company, in this city.

EXCESSIVE LUBRICATION SEAT OF EVILS

The smoke nuisance, dripping of oil on the pavement, and attending evils, is a subject which may lead to drastic legislation unless users of cars can be brought to a full realization of the necessity of maintaining a proper adjustment of the lubricating system and carburetor. President George J. Dunham, of the Royal Tourist Car Company, points out that carelessness is at the bottom of these evils in the main, although faulty motor construction can be regarded as having to do with the situation. Excessive lubrication, in the event that piston rings are poorly fitted, is a prolific cause of smoke, and the old-fashioned method of splash oiling accentuates the condition. In the old system of oiling, no provision was made to fix the oil level, and a careless chauffeur was thereby provided with every facility for producing the undesired smoke.

PROMISING CONDITIONS FOR ELMIRA SHOW

Arrangements are completed for the holding of the first annual automobile show in the State armory in Elmira by the Elmira Chamber of Commerce. The show will be held in the State Armory, opening at 8 o'clock Saturday evening, April 9th, and closing the night of April 16th.

The show is to be run by the Elmira Chamber of Commerce and the following committee will be in charge: John M. Connelly, president Chamber of Commerce, chairman; Clay W. Holmes, president, and Fred H. Rees, secretary, of the Elmira Automobile Club; Ralph W. Webster, of the Eclipse Manufacturing Company; E. deN. Sands, general superintendent of the American LaFrance Fire Engine Company; Hamlin Bryan, Southern Tier Motor Car Company; Ward LaFrance, LaFrance Motor Car Company; Benjamin Record, White Motor Car Company; Gordan Roberts, Rambler Motor Car Company; Major John T. Sadler, Second Battalian, 3d Reg. N. G. N. Y.; Captain W. A. Turnbull, 30 separate companies, N. G. N. Y.; Edwin Morrow, Morrow Manufacturing Co.; Roy S. Smith, secretary, Elmira Chamber of Commerce. The latter is secretary and treasurer of the show.

MONTREAL EXHIBITION AT COLISEUM

Montreal, March 21—The 1910 Automobile, Motor Boat, Accessories, and Sportsmen's Exhibition will open at the Coliseum, corner of Guy and Dorchester streets, on March 26 and run until April 2 inclusive. It will be held under the auspices of the Automobile Club of Canada, the Board of Directors of which are as follows: President, Clarence F. Smith; vice-president, U. H. Dandurand; directors, F. H. Anson, William Caruthers, D. McDonald, Eugent Tarte, A. J. Dawes, W. A. Edwards, F. H. Markey, L. C. Rivard, Geo. A. McNamee, secretary-treasurer.

The Coliseum is one of the largest buildings of this kind in Montreal, and is particularly well adapted to exhibitions of this character. An effort is being made to contrive decorations which will far exceed anything heretofore undertaken, and flying machines will be utilized to enhance the effect. A representative of the club went to France especially to purchase two of the best types for exhibition purposes.

CHAUFFEUR BILL AGITATES CANADA

A bill is before the House of Commons, Ottawa, to amend the Criminal Code, making it a criminal offence for chauffeurs to take out their employers' cars without their consent. The purpose of this act is to put an end to "joy-riding" by irresponsible parties, and is undoubtedly greatly in the interests not only of motorists, but of the general public.

The secretary has reecived a letter from Mr. Lloyd Harris, M.P., who has introduced the bill, requesting that each member of the club be urged to use his influence with his Member in Parliament to see that this bill, No. 75, is passed.

The section of this bill is as follows:

(a) "Everyone commits theft who takes or causes to be taken from a garage, stable, stand, or other building or place, any automobile or motor vehicle, with intent to operate, or drive, or use, or cause or permit the same to be operated or driven, or used, without the consent of the owner."

MAKER OF STERLING CAR RECAPITALIZES

Elkhart, Ind., March 21—The Elkhart Motor Car Company, this city, which makes the Sterling car, has increased its capital stock from $200,000 to $1,000,000, and plans are being made for the doubling of the present plant. For several weeks past various Michigan men have been trying to persuade the company to move to Detroit, but the company has consistently refused to entertain any such proposals. An additional frontage of 1,000 feet has been secured adjacent to the present plant. In the future the company expects to build all its own parts, and will begin making engines within two months.

HEWITT MOTOR COMPANY ABSORBED

When the Metzger Motor Car Company took over the Hewitt Motor Company of New York, it was done with the idea of acquiring membership in the A. L. A. M., and the question of the truck business remained open with a view to further discussion. It is now decided to complete the capitalization of the Metzger Motor Car Company on a basis of $1,000,000, and to build a $100,000 plant which is to be devoted exclusively to commercial automobile building. The ground for this new undertaking will be in Detroit, at some distance from the present plant of the Metzger Motor Car Company, and the first structure to be placed thereon will have a frontage of 100 feet, a depth of 300 feet, with three stories above grade.

This is another indication of the trend in the direction of commercial automobiles, and, considering the foundation which Edward R. Hewitt laid for commercial cars, it is anticipated that the new Metzger move will develop rapidly and assume huge proportions.

It was several years ago that Edward R. Hewitt, who is one of the pioneers in automobile work, came out with the Hewitt truck, which was after he had designed and constructed a line of gasoline pleasure cars, following his first experiment in steam work. The Hewitt business developed in New York along conservative lines, the idea being to limit the truck building to definite products, for which there is a strong demand, but which requires trucks of the very best possible design.

The new plan takes into account the experimental work which was conducted by Mr. Hewitt, and will make it possible to take advantage of his efforts in this field.

ROCHESTER AUTOMOBILE CLUB WILL DINE

Rochester, Mar. 23—The annual election of officers of the Automobile Club of Rochester will take place on Monday, March 28, and the annual banquet will follow. Complying with the usual custom, many stunts will be witnessed. An unusual menu card will be a burlesque fac simile of the club publication. Each guest will be presented with a souvenir. The following slate of officers is nominated to be elected: President, H. G. Strong; first vice-president, W. C. Barry, Jr.; second vice-president. W. W. Hibbard; treasurer, W. W. Dake, and secretary, Bert Van Tuyl. Directors for three years, W. C. Likly, C. J. Brown, Robert C. Shumway and W. R. Potter.

U. S. MOTOR COMPANY CRYSTALLIZING

With the new general offices of the United States Motor Company in process of completion at 505 Fifth avenue, New York, the details of the organization are being completed, and a general purchasing department, under the management of A. R. Cormully, is now established there. One of the advantages of a big merger such as this lies in the better command of the market from the point of view of the quality of material which may be had, and the more consistent prices.

DATE OF A.A.A. RELIABILITY NOT FIXED

Contrary to the general report the A.A.A. Reliability Run for the Glidden Trophy has not as yet been fixed, although it is the general impression that the matter will be taken up by the proper committee on Wednesday, March 29, and it is the expecation that the run will be started in the middle of June. Weather and other conditions will influence this date.

RAPID COMPANY LOSES ITS MANAGER

Pontiac, Mich., Mar. 19—Harry Hamilton, the general manager of the Rapid Motor Company, died here after a week's illness of acute nephritis. He is survived by a widow and two children. Mr. Hamilton was one of the company's most valued officers, and his loss will be keenly felt.

NEW 2-CYCLE MOTOR EXHIBITED AT A. C. A.

New York, Mar. 23—Last night a two-cycle fuel injection type of motor of the Newcomb design, was placed on exhibition under running conditions, at the Automobile Club of America, and by means of lantern slides, a very interesting talk was illuminated, resulting in the disclosure of many points of unusual interest embodied in this motor. An examination of the motor discloses the two-cycle principle of the conventional design, and the particular improvements which were enlarged upon involves the use of a fuel injection pump so arranged that the quantity of fuel and the timing of the injection are variable at will by the operator, through the medium of a plunger "stop" in conjunction with a means for the angular displacement of the pump cam. The fuel is injected directly into the cylinder after the air enters, and the power of the motor is varied by changing the quantity of fuel, considering a constant volume of air. It was claimed that the thermal efficiency of this motor proved on test to be about equal to that of the Deisel motor. Any such performance, if it can be borne out in practice, will represent a great advance. One other claim for this motor is that its thermal efficiency does not decrease rapidly when the load is reduced.

DETROIT CONCERNS MULTIPLY CAPITAL

Detroit, Mar. 19—The Regal Motor Car Company has increased its capital stock from $100,000 to $1,000,000. The former figure has for some time been merely nominal, as the business of the company had long outgrown it. The new figure represents a truer valuation, with a considerable surplus of new capital which can be devoted to extensions and improvements in the plant and equipment of the company.

Almost coincident with the Regal announcement comes the news that the Hupp Motor Car Company, also of this city, which makes the Hupmobile, has seen fit to multiply its capital by five, raising the figure from $50,000 to $250,000.

200-H.P. BENZ GIVEN CERTIFICATE

Chairman Butler, of the Contest Board of the A. A. A., has issued a certificate to Barney Oldfield, who drove the 200-horsepower Benz car at Daytona Beach, March 16, the records being as follows:

(a) One mile flying start, 27:23.

(b) One mile standing start, 40:53.

The certificate states "the above are world's records and are unequaled by any other performance made up to the present time."

A.L.A.M. WILL DINE AT HOTEL ASTOR

With 80 members on the list, the A. L. A. M. will hold a dinner at the Hotel Astor on April 7. The committee in charge comprises H. B. Joy, chairman; H. A. Lozier, Albert L. Pope, Benjamin Briscoe and R. E. Olds. It is anticipated that the members and guests, in order to be properly cared for, will fully tax the capabilities of the Hotel Astor.

TWO MORE COMPANIES JOIN A.L.A.M.

The latest advices from the A. L. A. M. are to the effect that the Chadwick Engineering Works of Pottstown, Pa., maker of the Chadwick car, and the Atlas Motor Car Company, of Springfield, Mass., maker of the Atlas car, were admitted to the association.

CHANGES IN PACKARD PERSONNEL

S. D. Waldon has moved up in the Packard organization and is now vice-president. His place as general manager has been assumed by Alvin Macauley.

SUMMARY OF 1910 RELIABILITY CONTEST RULES

THE most important amendment to the reliability contest rules for 1910 over those of last year will be found in the adoption of the fixed penalty schedule, which is applied at the final examination of the cars at the completion of a contest. In this schedule each of the essential parts of a car are given a definite number of points penalty for defective condition, greater or less, according to their relative importance to the whole make-up of the car and the condition in which such part is found at the finish of the contest.

SUMMARY OF PENALTIES.

One point per minute, or fraction thereof, late in arrival at any control or checking station.

One point per man per minute, or fraction thereof, for labor by driver or passengers.

Two points per man per minute, or fraction therof, for labor by workmen other than driver or passengers.

Two points per man per minute, or fraction thereof, for replacement of damaged parts by driver or passengers.

Four points per man per minute, or fraction thereof, for replacement by workmen other than driver or passengers.

Three points per occurrence for replenishing gasoline, oil or water, outside of fuel controls.

One point per minute, or fraction thereof, for motor stop when no work is done. No penalty for motor stop during period when work is being done on car, for which work or replacement a penalty is imposed.

FINAL OUT-DOOR OPERATIVE TESTS

Brake Penalties—50 feet perfect; for each foot, or fraction thereof, over this distance, 1 point.

Clutch—5 points for failure to climb curbs, spin rear wheels or stall motor.

Gear Set—25 points for failure to drive on any forward speed or reverse.

Motor Test—5 points for each cylinder not firing.

Front and Rear Axles—No penalty for one-fourth inch spread between wheels; 5 points for each additional one-eighth inch, or fraction thereof.

Springs—No penalty for sag of one inch; 5 points for each additional one-half inch, or fraction thereof.

FINAL EXAMINATION PENALTY

At the close of the contest, each competing car, after being properly washed, shall be delivered to the Technical Committee, who shall record all adjustments, replacements or repairs necessary to place each car in a safe and satisfactory condition, and penalties therefore shall be imposed in accordance with the following Fixed Penalty Schedule:

LUBRICATION

Broken oil feed	3
Inoperative oil feed	3
Leaky oil connection	1
Loose oiler	3
Disabled oiler	20
Lost grease cup	2
Loose grease cup	1

CARBURETION

Broken gasoline line	2
Leaky gasoline line	1
Leaky gasoline tank	1
Leaky gasoline petcock	1
Disabled throttle control	15
Broken or loose manifold	15

BRAKES

Broken operating devices	100
Broken brake	100
Loose operating devices	25

RUNNING GEAR

Broken spring leaves, each	5
Broken spring clips, each	15
Broken spring seating	15
Loose spring clip	1
Loose spring horn	15
Broken frame side member	500
Broken frame cross member	150
Bent frame pieces	75
Broken strut rods	25
Broken torsion rod	25
Lost muffler	5
Broken muffler	3
Loose muffler	2
Broken wheel	100
Loose wheel spoke	5
Broken wheel spoke	10
Broken running board	6
Broken fender iron	6
Broken fender	5
Loose fender	2
Lost mud apron	8
Broken mud apron	5
Broken rear axle	300

COOLING

Leaky water connection	1
Leaky radiator	20
Loose radiator	4
Disabled water pump	15
Inoperative fan	2
Leaky water jacket	50
Fan belt off	1

IGNITION

Loose terminal	1
Broken terminal	2
Dead battery	2
Lost commutator cover	2
Disabled commutator	20
Inoperative ignition control	5
Disabled magneto	20
Loose magneto	4

STEERING

Broken tie rod or drag link	200
Bent tie rod or drag link	25
Broken steering rod	200
Bent steering rod	25
Faulty steering gear	200
Loose steering connections	15
Broken steering knuckle	150
Bent steering knuckle	15
Broken front axle	300

MACHINERY PARTS

Broken valve	5
Broken or impaired valve spring	2
Broken cam	500
Broken camshaft	200
Broken crankshaft	500
Bent crankshaft	250
Broken valve rocker arm	10
Broken push or valve lift arm	10
Broken transmission shaft	100
Broken cardan shaft	100
Broken driving chain	30
Broken gear or pinion	25
Broken bearings	10
Broken body or chassis bolts	2
Loose body or chassis bolts	1
Lost body or chassis bolts	2
Broken clutch	250
Broken or impaired universal joint	50
Broken or lost bonnet fastener	2
Loose bonnet fasteners	1
Broken or impaired sprags	5
Broken shock absorbers	5
Loose shock absorbers	2

STEAM

Leaky condenser	20
Leaky generator	50
Faulty thermostat	20
Faulty pilot light	20
Faulty flow motor	20
Faulty gauge	5
Steam leak in line	1
Water leak in line	1

(In cases of leaky radiator or water jackets, recognition must be taken of the degree of leakage and the amount of fixed penalty modified accordingly.)

GRADES OF CONTEST

Reliability contests are graded as follows:

Grade I—A contest not exceeding six (6) days in duration, with penalties for time, road work, final operative test and final technical examination.

Grade II—A contest of more than six (6) days' duration, with penalties for time, road work, final operative test and final technical examination except that carburetor and brake adjustments may be made without penalty and spark plugs may be changed.

Grade III—A contest of any duration in which penalties are imposed for time and road work only, but in which the final operative test and final technical examination are omitted.

Grade IV—A contest of any duration in which penalties are imposed for time only.

NON-STOP RUN

For the "perfect road score" of the old rules there has been substituted a "non-stop run" defined as follows:

A run without an involuntary stop of the car outside of controls, except for tire trouble or on account of traffic congestion, shall be known as a non-stop run.

The motor must be kept running continuously while outside of controls.

The car may be brought to a standstill at any time, no work being done, and the motor kept running.

Stops for tire repairs or replacements with the motor kept running, are permissible.

Non-stop certificates may be issued to contesting cars in Grades 1 and 2 who conform to the requirements of the "Non-Stop" definition in a contest exceeding 1,000 miles in length.

CAR EQUIPMENT

Just what equipment a stock car may or may not carry in reliability contests is very clearly laid down. It may carry special mud aprons in front of radiator or bonnet screens between the side members of the frame; rubber bumpers for springs, and rebound straps; tire inflating tanks. It may not have special springs or spring windings; shock absorbers may not be added unless part of regular equipment and covers over coil boxes, magnetoes or any other part of mechanism, or screens around carburetor, are not permitted unless part of regular equipment.

TOOLS

Tools are carried in a special bag and sealed, the observers only having access to same.

PARTS

Parts carried are inventoried, officially checked and sealed.

Tire Repairs—There shall be no penalty for tire repairs, provided the engine be kept running while the repairs are being made and no other work is done. The time consumed in making the repairs, while the engine is running, shall be added to the day's running time.

Oil, Gasoline, Water and Batteries—At noon or night controls, tanks for lubrication oil, gasoline and water may be filled without penalty.

For replenishments of oil, gasoline or water at any other places the penalty is 3 points for each occurrence.

Oil or grease may be added to or may be drawn off the various cases when necessary without penalty during the half hour allowed for oiling at the end of each day's run.

Recharging of batteries will be allowed at any time, but all work in connection therewith must be done in the presence of the observer.

SEALS

To enable an observer to keep a more accurate record of work done on a car, metal and wire seals will be affixed to the bonnet, coil box, transmission case, differential case, mud pan or apron and parts of ignition system not protected by bonnet seals and any other parts, as may be necessary. There will be no penalty for breaking a seal, which will be replaced at the official garage at the end of a day's run, but the observer will note the seal broken and must report how many times thereafter access was had to the part or parts protected by such seal.

LUBRICATION

A half hour is allowed at the end of each day's run for proper lubrication of the car in the official garage, seals being broken for this purpose and replaced.

OBSERVERS

The rules concerning observers have been broadened and strengthened and the duties of observers enumerated in greater detail than heretofore, the following rule among others having been added:

Observers must not interpret rules for entrants or drivers and cannot say what work may or may not be done without danger of penalization, their duties being solely to record what is done and the exact length of time consumed in doing it.

To induce entrants, who appoint observers, to use the greatest care in their selection, the following penalty is imposed on an entrant for the act of an observer he has appointed:

If an official observer shall desert a disabled car without first obtaining the driver's signature to a statement that he has withdrawn from the contest the entrant who appointed such observer shall be disqualified and must either withdraw from the contest altogether or continue as a non-contestant. By desertion is meant leaving the car without taking with him the driver and passengers. This rule will disqualify but one of the cars of an entrant in case of multiplicity of entries.

OPTIONAL PROVISIONS

The following provisions, the adoption of which in any contest is optional with the promoter, and none of which count against a car or are factors in determining the car's road score, have been added:

Rules for tire penalizations.

Rules for penalization of accessories.

The keeping of a record of lubricating oil and of gasoline consumption.

CLASSES FOR DAILY RUNNING TIME

Reliability contests shall be held under Class "A" (price classification) only and run in the seven divisions of such class, as follows:

Division 1A.............	$ 800 and under
Division 2A.............	801 to $1,200
Division 3A.............	1,201 to 1,600
Division 4A.............	1,601 to 2,000
Division 5A.............	2,001 to 3,000
Division 6A.............	3,001 to 4,000
Division 7A.............	4,001 and over

on which the daily time of the cars is based.

The following average speeds shall be maintained by the cars in the respective divisions:

Divisions 4A, 5A, 6A and 7A..20 miles per hr.
Divisions 2A and 3A...........18 miles per hr.
Division 1A..................16 miles per hr.

BODY EQUIPMENT CLASSIFICATION

Stock cars only are eligible, and for the purpose of trophy awards shall be divided into two classes according to body equipment: (1) touring car class; (2) runabout class, including runabouts, miniature tonneaus, surreys and double or single rumbles.

(Official) Contest Board
American Automobile Association.
March 19, 1910. S. M. BUTLER, Chairman.

EXCITING SECOND DAY OF DAYTONA RACING MEET

DAYTONA, FLA., Mar. 22—The opening of the three-day tournament, which is being held under the auspices of the Florida East Coast Association on Daytona Beach, promises to be very interesting, despite tidal interferences during the racing hours on Tuesday. The one mishap for the first day was to the automatic timing apparatus, which was traced to a short-circuit caused by salt water, following an unusually high tide. In the absence of suitable timing equipment, the one-mile speed trial, and the five-mile free-for-all championship were put off until Wednesday. These events were what the spectators wanted to see, because they include the Benz car and the Christie front wheel drive. The Benz having recently broken two world's records against time, is naturally looked upon as a most interesting performer.

As it turned out for the first day, Oldfield drove his Knox car in two of the races. He was first in the twenty-mile race against Gus Grosjean in a Pope-Hartford, but the difference was only by inches. A Chalmers "40," driven by Harry Olmsted, led in this event to the tenth mile turn, but was beaten out through stalling his motor at the turn.

The ten-mile free-for-all attracted some notice, and proved to be very exciting for a time. In this event Ormsdorf, in a Chalmers "30" crossed the line first, and 100 yards before Aultman in a Hudson "20." Hildebrand in a Chalmers "30" was third. Allen Whiting of the Automobile Club of America, representing the Contest and Technical Board of the A. A. A., presented a cup to the winner of the ten-mile handicap free-for-all.

DAYTONA, FLA., Mar. 23—To-day the conditions proved to be ripe for record-breaking time, and the annoying incidents of the first day's work were entirely eliminated.

Referring to Oldfield's new world record of 17.4 seconds for a kilometer with a flying start, it is pointed out that the previous world's record was 17.76 seconds, made by Hemery on Brooklands Track, England, in the same car. It is also to be observed that Oldfield's time for the two mile world's record of 55.87 seconds is considerably faster than the previous record of 58 4-5 seconds, which was made by Demogeot at Daytona in 1906.

Summary of First Day's Contest

Ten-mile Southern Championship—Won by Gus Grosjean, Pope-Hartford; R. M. Bond, Stearns, second; W. E. Davis, Chalmers, third; E. Hildebrand, Mitchell, fourth. Time 9 27-100.

Twenty-Mile Open Stock Car, free-for-all—Won by Barney Oldfield, Knox; Gus Grosjean, Pope-Hartford, second; Harry Ormsdorf, Chalmers, third. Time 18 60-100.

Ten-Mile Handicap, free-for-all, for the Allen H. Whiting Trophy—Won by Harry Ormsdorf, Chalmers (2:30); M. B. Aultman, Hudson (6:30), second; E. Hildebrand, Chalmers (5:25), third. Time 9:09 20-100. Other cars finished as follows: Barney Oldfield, Knox (1:30), R. M. Bond, Stearns (2:30), W. E. Davis, Mitchell (6:00), David Bruce Brown, Benz (scratch). Mile exhibitions by Oldfield in Benz and Walter Christie in Christie car. No time taken.

Summary of Second Day's Contest

One Mile Championship trial against time, won by Oldfield in Benz car; time 28 2-5 seconds. George Robertson in Christie front wheel drive car, second; time 30.39 seconds.

Stock Car record for one mile with flying start, Oldfield in Knox; time 40:35 seconds.

Florida Ten Mile Championship Race, won by Hotchkiss in Pope-Hartford; time 9.41 seconds. Bond in Stearns car, second; time not given.

Flying Kilometer Record, Oldfield in Benz; time 17.4 seconds.

Two Mile World's Championship, from a flying start, Oldfield in Benz; time 55.87 seconds.

Ten Mile Free-For-All Stock Chassis Race, Oldfield in Knox car; time 8 min. 41 sec. Ormsdorf in Chalmers 40, second; time not given.

Ten Mile Handicap, David in Chalmers 40; time 12:13. Hotchkiss with Pope-Hartford, second; time not given.

200-horsepower Benz racing automobile driven by Barney Oldfield on Florida Beach on March 23, making world's record of 17.4 seconds for flying kilometer, against previous record of 17.76 seconds made by Hemery, at Brooklands track, in the same automobile.

AMONG THE GARAGES

Salesroom and garage of Collins & Dulaney, at Paris, Tex., a structure of pressed brick, with concrete floor and metal ceiling, 50 by 100 feet on the ground plan

E. J. Moon, sales manager of the Moon Motor Car Company

Work has been started on the garage of the Reimers Motor Car Company, of Louisville, Ky., and will be rushed to completion. The plans call for a two-story structure of concrete and brick, 52 by 125 feet. The entire lower floor will be used as a garage, and will have space to accommodate about eighty cars. The second floor will be used as a repair shop, with modern equipment. The building is located in the rear of the present quarters of the Reimers Company, and will be used as an addition. The present building will be remodeled into show rooms and offices.

The fireproof garage of the White Automobile Company, at 949 Main street, East Orange, N. J., has been acquired by J. J. Meyer, of Orange. The building has a capacity of 75 machines, besides a repair shop. Mr. Mayer will make alterations, and will in addition to the garage business handle the Auburn.

William Olson and E. A. Ludvall have leased the Mount Vernon Automobile Station, at Third and Prospect avenues. Mount Vernon, N. Y., and will continue the business formerly conducted there by Chester A. Stephenson.

Athens, Ga., automobilists have a new accommodation since the recent opening of the Bishop Motor Car Company's garage on Washington street. The building is 62 by 110 feet, two stories high, and has a capacity of fifty cars. The Bishop Motor Car Company has the local agency for the Peerless, Stoddard-Dayton, Courier, Maxwell, Overland and Johnson.

The Jeannette Machine Company, of Jeannette, Pa., which has the agency for the E-M-F and Flanders, is constructing a two-story garage at 10 South Second street. The building will be of buff brick, 40 by 100 feet. The first floor will be used as a garage and salesroom, and the second as a machine and repair shop.

S. N. Taylor will build a $40,000 garage at 5207 Delmar boulevard, St. Louis. The building will be of brick, 124 by 150 feet. The floor space will be divided into two parts, one to be occupied by the Park Automobile Company, and the other by C. F. & J. R. Brown, automobile agents.

The Johnson Auto Company, of Boone, Ia., will open a garage in the Grove Building, on Lynn street, Nevada, Ia. Work on remodeling the building has already been begun. The new company will be under the management of J. R. Davidson and will handle the Cole "30."

The Burdell Auto Sales Company, which has the Columbus, O., agency for the E-M-F and Flanders, is now located in its new salesroom at 153 North Fourth street, that city. The salesroom is 40 by 110 feet. F. G. Burdell is president and general manager.

The Electric Auto. Station, of Hartford, Conn., at present located at 19 Hoadley place, contemplates building a garage on Church street, below High, a more prominent location, and is having plans drawn up to that effect.

The Park Car Company, of Henderson, Ky., has taken the agency for the Moon and Regal and will open a garage on First street, near Greene, under the management of James B. Morgan.

Another garage will be added to the row on North Broad street, Philadelphia, by Irwin & Leighton. The new building will be at No. 326-328, and will be one story in height, to cost $9,500.

Thomas Hawkins, of Philadelphia, has accepted plans for a garage on the corner of Airdrie and Watts streets. The building will be two stories in height, 17 by 27 feet, to cost $4,000.

Brief Personal Mention

Julian A. Halford, managing director, Commercial cars. Limited, Luton, with headquarter offices at Cambridge Circus, London, W. C., is favoring America with his presence, partially with the expectations of making arrangements with some first-class establishment which will be able to exploit the commercial automobiles made by this company. THE AUTOMOBILE enjoyed a brief visit from Mr. Halford, and his mail address will be 164 West Eighty-first street, New York City, during the term of his visit.

It was erroneously stated in last week's THE AUTOMOBILE that M. S. Keyes, formerly with Maxwell, had taken the agency for Regal cars in the territory surrounding New York City. This was not the case, for Mr. Keyes has taken a position with the Regal Motor Car Company, as district manager for that district.

A. J. Rousseau, formerly manager of the Chicago Buick branch, has been appointed district manager of the Willys-Overland Company for Illinois, Iowa, Eastern Nebraska, Southern South Dakota, Minnesota, Northern Indiana and Western Michigan.

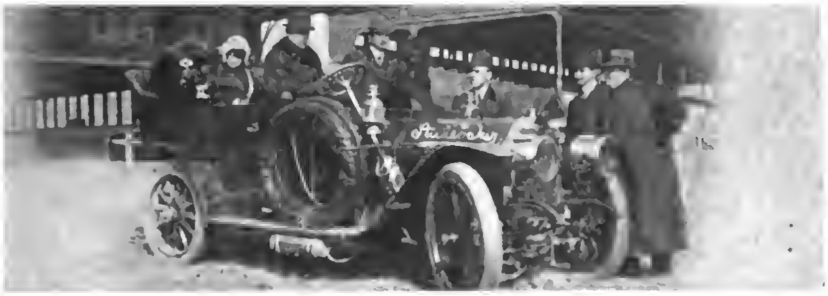
C. T. Brewster, formerly manager of the Cleveland branch of the United Manufacturers, is now connected with the Olds-Oakland Company in the capacity of State and city salesman.

R. B. Tracy, for several years Cleveland branch manager of the Michelin Tire Company, has been transferred to Chicago. As yet no one has been appointed to succeed him.

J. M. Clarke, formerly sales manager of the National Motor Vehicle Company, Indianapolis, Ind., has resigned from that position to take the agency for the National car in Denver, Col.

F. R. Bump, formerly with the Franklin Manufacturing Company, Des Moines, Iowa, has become sales manager of the Owen Motor Car Company, of Detroit, Mich.

WITH THE AGENCIES



Mme. Paulhan, the wife of the French aviator, and her friend Mme. de Pennendreff, at Jamaica Park, L. I., waiting for Paulhan to make a flight in his Farman biplane

Will Christy, vice-president of the Firestone Tire Company

COLUMBUS, O., March 19—With the passing of the season of changes in automobile agencies in Columbus, O., the announcement is made of the agencies which will have charge of the sales of cars during the season of 1910. Since the closing of the motor show given under the auspices of the Columbus Automobile Club, the agents have been busy and sales are numerous. The inclement weather has caused a delay in deliveries but the weather has not affected the sale of cars materially. Deliveries will be made during March and April, allowing time for the factories to catch up on orders.

A complete list of Columbus sales agents follows: F. E. Avery, 1199 Franklin avenue, Packard and Waverly Electric; The Burdell Auto Sales Company, 153-155 North Fourth street, E-M-F and Flanders "20"; The Robert F. Boda Automobile Company, 30 West Main street, Mitchell and National; the Columbus Buggy Company, Fourth and Gay streets, Firestone-Columbus and Columbus Electric; The Curtin-Williams Company, 122 South Parsons avenue, Cadillac, Winton. Peerless and Baker Electric; Broad-Oak Auto Company, 621 East Broad street, The Chalmers, Hudson and Pierce-Arrow; The Franklin Motor Car Company, Fourth and Spring streets, Franklin and Reo; The Charles Schiear Motor Car Company, Fourth and Spring streets, Hupmobile and Velie; The American Auto Company, Fourth and Spring streets, American; The Speedwell Company, Fourth and Spring streets, Speedwell; Howald and Wilkinson, Fourth and Spring streets, Buick and Welch-Detroit; Eclipse Auto Company, 955 South High street, K-R-I-T; The Central Ohio Motor Car Company, 61 East Spring street, Olds and Oakland; O. G. Roberts and Co., 933 East Gay street; Lexington, Marion, Overland, Jackson, Stearns and Stoddard-Dayton; The Francisco Automobile Company, 856 North High street, Ohio; The Ohio Motor Car Company, West Russell street, Ford; the Studebaker Company, Fourth and Chestnut streets, Studebaker; United States Carriage Company, 309 South Fourth street, Apperson, Great Eagle and Rauch Lang; Maxwell-Briscoe Columbus Company, 58 to 62 East Spring street, Maxwell; Iroquois Auto Company, 17 West Mound street, Empire and Grabowsky truck; Williams and Schlereth, East Long street, Pope-Hartford; The Love Garage Company, High street and Sixth avenue. White and Cole "30"; The Franklin Cycle and Supply Company, East Gay street, Demot; The Early Automobile Company, High and Town streets, Rambler, Babcock Electric, Whiting, Paterson and Warren-Detroit; R. C. Westcott, 958 North High street, Regal; Reliance Truck and Transfer Company, Third and Lynn streets, Reliance trucks; Miller Machine Company, 705 Ann street, Premier.

The Otto Gas Engine Company, of Philadelphia, which attracted much attention at the Palace show with its new Otto car, has established a New York agency at 144 W. Thirty-ninth street.

C. W. Matheson, president of the Matheson Automobile Company, entertained his friends of the fraternity at a luncheon which was given on March 22 at 12.30 P. M. The guest of honor on this occasion was the "Silent Six Matheson."

N. Lazarnick, commercial photographer, has opened a branch in Detroit, Mich., at 870 Woodward avenue, under the management of Milton B. Kolb. This arrangement puts Lazarnick in a position to do prompt work in the photographic line.

Latest advices from the Jeffery-Dewitt Company, spark plug manufacturers, 217-219 High street, Newark, N. J., is to the effect that this well-known product will hereafter be manufactured in a well-equipped plant at Detroit, Mich.

The Whiting sales agency has opened headquarters at 111-115 South Beatty street, Pittsburg, and will have the exclusive agency for the Whiting "20" and the Whiting "40" cars made by the Flint Wagon Works Company of Flint, Mich.

R. H. Ohr, Mercer, Pa., has bought the Oldsmobile agency of Alpha M. Brown, in New Castle, Pa., and will also have the Oakland agency in that city. He has for years handled the Oldsmobile cars in Mercer, Pa.

The Automobile Manufacturers' Clearinghouse is the latest second-hand agency to be established in Pittsburg. Its manager is W. H. LaFontaine, and it will have headquarters in Euclid Avenue, East End.

Warner speedometers will henceforth be sold in Pittsburg through a direct branch office. The branch is located at 5940 Kirkwood street, with C. J. Clapp in charge as manager.

The Grout Automobile Company, of Orange, Mass., has opened a Boston branch at 218 Elliott street. E. P. Forbes will act as manager to conduct the sales of the "Powerful Grout."

The Francisco Motor Car Company, of Columbus, Ohio, agent for the Ohio, has located a salesroom and offices at 856 North High Street. It was formerly located on the viaduct.

Thomas W. Meiklejohn and P. B. Haber, of Fond du Lac, Wis., have the agency for the Ford in that city and surrounding territory.

F. A. Emerson, Angola, Ind., has secured the agency for the Clark cars for northeastern Indiana.

FARMERS OPPOSE MUNICIPAL AUTOMOBILES

WILMINGTON, DEL., March 19—The Grangers are almost unitedly opposed to the proposition of the Levy Court, the governing body of New Castle county, providing itself with two automobiles, for the purpose of supervising the county roads and bridges, nearly every Grange in the county having adopted resolutions of protest. The court is to reach a decision at its next meeting, when the bids are to be opened.

REALM OF THE MAKERS

Out for a spin in an Inter-State car on one of the good highways of northern Indiana. On such a road the Inter-State can be counted on for close to a mile a minute

F. H. Wheeler, of Wheeler & Schebler, Indianapolis

Among the interesting features in tire construction at the Boston Automobile Show, the Bragg stitched tire seemed to attract a large percentage of the interest. Thorough tests have been made with the tire for the past three years and it was first put upon the market at the New York automobile show last January. The manufacturers of this tire claim that they have eliminated the separation of fabric by the stitching process and they guarantee to make satisfactory adjustments on a 5,000-mile basis. J. V. Alden, the president of the Seamless Rubber Company of New York and general sales manager of the tire, together with his associate, Mr. Williams, gave their personal attention to their exhibit at the show. They report that their success has far surpassed their most sanguine expectations and that the prospects for their business in New England are very pleasing.

The J. I. Case Threshing Machine Co., of Racine, Wis., largest concern of its kind in the world, has placed an order for twenty-five Model 38 Overlands with the American Motor Car Sales Co. at Toledo. In place of the rumble seat, a special body, consisting of a receptable like a box, is provided, these being furnished by the Racine Manufacturing Co. Three case "transfers," or emblems are to be placed on each car, one on each side of the hood and one on the box. A smaller eagle transfer will appear on each side of the seat. It is not announced what use will be made of these cars, but it is expected that the Case company's representatives in the larger cities of the country will be provided with them, the box compartments being used for catalogues, tools, small repair parts and literature of all kinds.

Tires should always be kept inflated so hard that they stand up round and full under the load, say tire men. The Diamond Rubber Company puts this rule ahead of all others, even that of pressure gauges, because the latter does not provide for the overloaded tire. Ample inflation is urged as the most important thing for the automobilist to consider in getting maximum mileage from whatever make of tire he uses. Extensive service tests have proved this fact. Ample inflation checks the movement within the tire and reduces the element of friction and heating, produced to a great extent when tires are run partially flat. These facts put it up to the automobile owner to get the best service out of his tire equipment. The tire manufacturers are responsible for the casings and tubes but obviously the tire user must furnish the air.

Cross & Brown Company sold for Aline D. Elliott and J. S. Dickerson to Louis C. Jandorf, president of the Broadway Automobile Exchange, the northeast corner of Eleventh avenue and Fifty-eighth street, New York, a two-story and basement factory building, on a plot 100 by 100. After extensive improvements the purchasers will occupy the premises for the manufacturing end of their automobile business.

The Federal Rubber Company of Illinois has established quarters in Chicago at 1312 Michigan avenue. They will handle the Federal tire. C. C. Harbridge, J. C. Zimmerman, William Seward and Hugh Jackson are interested in the company. They were all formerly with the Chicago Michelin branch. Mr. Harbridge's successor as manager of the Michelin branch is Richard Tracy, of Cleveland.

A new booklet containing valuable suggestions to motorists on the correct air pressure for their tires is being distributed by the Firestone Tire and Rubber Company, Akron, O. It also contains recommendations on the most economical sizes to use for various loads, together with other useful data on tires and quick detachable demountable rims.

The Willard-Harlow Manufacturing Co. of Janesville, Wis., has been granted a charter in Wisconsin. The company is capitalized at $25,000. The purposes of the concern are to manufacture and deal in motor car specialties and steam heating appliances. J. C. Harlow, A. E. Bigham and P. H. Korst are the incorporators.

The Chalmers Company has selected Morgan & Wright "nobby tread" tires as equipment on the Glidden tour pathfinding car. These tires made a great record on the E-M-F pathfinding car last year and Morgan & Wright feel much elated that they have been again chosen for this, the hardest pathfinding job of the season.

The Mt. Clemens Motor Car Company, capitalized at $200,000, with $75,000 paid in, has filed articles of association at Lansing, Mich. The company will manufacture automobiles and parts and conduct a general foundry and machine shop at Mt. Clemens, a suburb of Detroit. The chief output will be a delivery wagon.

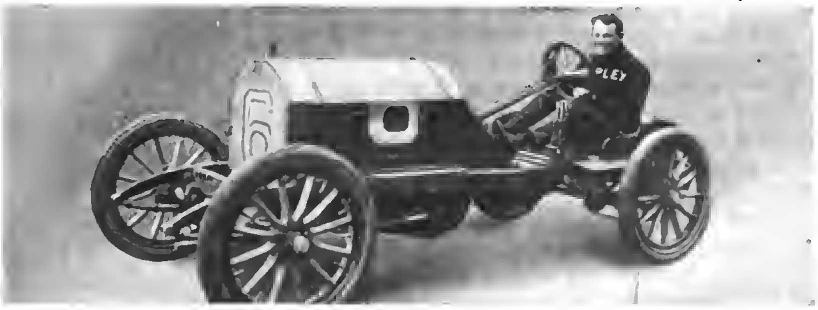
The Racine Sattley Company has contracted for the Halladay line for Central and Northern Iowa. E. A. Kiser, formerly with Cruzan & Company, Des Moines, has accepted a position with these people as manager of their automobile department, and will devote his entire time and efforts to this line.

Among the shipments last week of Premier cars from the factory of the Premier Motor Manufacturing Company was a four-cylinder touring car for Thos. W. Lawson of "frenzied finance" fame. This is Mr. Lawson's latest addition to a garage well stocked with some fine American and foreign cars.

The Mitchell-Lewis Motor Company, of Racine, Wis., issued its first limousine body type last week. This body is used on the regular Model S, six-cylinder, 50-horsepower chassis. The car was built for William T. Lewis, one of the founders of the Racine concern.

In Cleveland, the White Line Auto Express Company has been incorporated with a capital stock of $300,000 by L. B. Smith and others.

NEWS IN GENERAL



George Robertson in the 90-horsepower Simplex racer which he will drive at the Los Angeles races. The Vanderbilt winner uses Continental tires as his standard equipment

E. Le Roy Pelletier, advertising manager of the E-M-F Company

There is a sharp contest on this year between the railroads entering Pittsburg for the automobile freight business. Hitherto, the P. R. R. and the Pennsylvania company have practically controlled this business. This year, however, the Pittsburg & Lake Erie Railroad Company made a very strong bid to automobile shippers all along the New York Central lines, and as a result has been bringing in train load after train load of new cars for local agency.

One of the most interesting features of the fourth annual Pittsburg automobile show which opens March 26, will be the distribution of handsome souvenirs. The show committee has arranged for a mammoth collection of cut flowers that will be distributed every night to the lady visitors. The pennant will be in the show colors, yellow, canary and green, and will bear an immense painted design of "the girl at the wheel."

Tbe Keim Supply Company, of 1227 Market street, Philadelphia, Pa., has purchased the business of the Auto Light & Motor Supply Company, 506 North Broad street. They will retain the latter establishment for branch and storage purposes. E. C. Leeds is president of the company; H. C. Holinger, vice-president; Joseph A. Janney, Jr., treasurer; Joseph A. Steinmetz, secretary, and J. H. Rosen, manager.

The John Obenberger Company, of Milwaukee, Wis., has been reorganized and incorporated as the Obenberger Drop Forge Company and will make a specialty of automobile parts, continuing to produce steel hammered forgings. The capital stock is $30,000. The officers of the new concern are: President, John Obenberger; vice-president, Henry C. Fuldner; secretary and treasurer, H. W. Ladish.

H. W. McMaster, one of the receivers of the Wabash-Pittsburg Terminal Railroad Company, Peter K. Soffel, real estate manager of same company, and Frederick James, of Pittsburg, have formed the Reliance Motor Truck Company of Pittsburg which is applying for a Pennsylvania charter. They will have the Western Pennsylvania agency for the Reliance truck, manufactured at Oswego, Mich.

A company has been organized in Port Jefferson, L. I., to run electric automobile 'busses this Summer between Patchogue and Port Jefferson. It is called the Suffolk Transportation Company. The 'busses will connect at Port Jefferson with the steamers of the Bridgeport-Port Jefferson Company, the service to start about the first of July.

The third class in automobile operation, under the charge of the association institute of the Columbus (Ohio) Y. M. C. A., was organized February 28 with 42 pupils. This makes 135 pupils who are taking the course. The classwork consists of lectures and practical demonstrations in a workshop equipped with several automobiles.

The Willis-Holcomb Company is showing a line of Packard commercial cars, while the Percy-Willis Company, the Conduitt Automobile Company, the Cost and Orlopp and the Van Camp Automobile Company, all prominent Indianapolis dealers, are now selling commercial cars, this being "opening week."

Madison Automobile Company, Madison, Wis., has installed a complete tire, repair and vulcanizing plant, tbe largest in Wisconsin outside of Milwaukee. William A. Jackson, formerly in the Michelin Tire Works, of Milltown, N. J., is manager of this department. L. F. Schoelkopf is president.

It is said that efforts are being made by the International Association of Machinists to organize a Wisconsin district of employees of automobile and allied plants. Racine, Columbus, Corliss, Janesville and other cities will be included if the organization is effected.

J. C. Murdock, of Broadhead, Wis., has a patented automobile spring which, it is said, will be adopted by the Thomas B. Jeffery Company, of Kenosha, Wis., and the White Company, of Cleveland, is also said to be figuring on using it extensively.

The National Motor Supply Company, of Cleveland, Ohio, manufacturer of portable steam vulcanizers and gasoline tank gauges, has opened a branch at 1777 Broadway, New York. The Cleveland company was organized less than a year ago.

A. B. MacGowan, a well-known salesman of the Maxwell-Briscoe Pittsburg Company, has gone into business with N. H. Wishart. The firm will continue to handle the Flentje shock preventor and the Hoffecker speedometer in Pittsburg.

A movement has been started by capitalists at Jefferson, Wis., to use part of the big Vaughn Manufacturing Co.'s implement plant for the manufacture of a light farm motor wagon. The project is not yet in definite shape.

The Rowe Automobile Company, of Waynesburg, Pa., one of the most thrifty concerns in western Pennsylvania, will build a plant at Martinsburg, W. Va., at once to manufacture automobiles and gas engines.

The New Kensington Motor Company of New Kensington, Pa., has been formed by J. W. Vernam, New Kensington, Pa., J. S. McKee, Ambridge, Pa., and J. G. Silvens, Homestead, Pa.

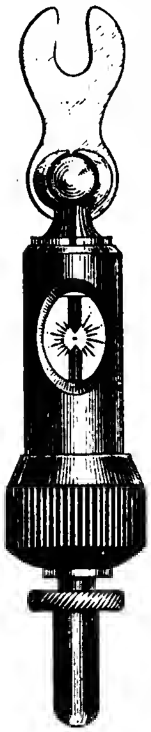
The Standard Automobile Company of Pittsburg is making rapid progress on its new building at Grant boulevard and Bellefield avenue, and will have its formal opening about May 14.

G. W. Laurie, salesman for Morgan & Wright in Boston and vicinity, will shortly assume a traveling position for the same firm, calling on the trade in the New England States.

The Mutual Manufacturing Company has been formed in Pittsburg by George Ferrer, A. J. Kraber and E. R. Cramer and will manufacture wind shields.

PROMINENT ACCESSORIES

REVIVING the old idea of the spark-gap, the New England Sales Company, of Boston, has brought out, under the name of the Phelps "Trouble Finder," a device to be inserted in the wiring between the coil or magneto and the spark plug to show whether the spark is jumping regularly. The "trouble finder" is designed to take the place of the usual high-tension terminal attachment to the spark plug. It consists of two points, separated slightly to form a gap across which the current must pass on its way to the plug. The points are properly insulated, and are inclosed in a brass tube, with a glass window through which one may watch the spark jumping across the gap. One of the points is adjustable by turning a milled nut on the outside of the tube, so that the length of the gap may be regulated.



"Trouble Finder"

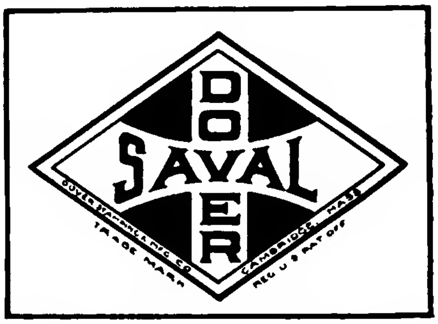
For ordinary service the points are adjusted quite close together, so as to introduce as little resistance as possible. In case one cylinder should be missing, it can easily be located by looking at the row of "trouble finders"; for if there is no spark in the cylinder, there will be none across the gap of the "trouble finder." Many other claims are made for the device, such as keeping the plugs free of carbon deposits, increasing the power of the motor, making it possible to throttle down to a lower speed, and making it possible to run on nearly exhausted batteries.

In connection with the description of accessory makers' factories in and around Boston, which appeared in a recent issue, a photograph was given of the plant of the Hood Rubber Company, at Watertown, Mass., part of which is occupied by the Shawmut Tire Company, and is the home of Shawmut tires. Owing to the limitations of the photographic art but a small part of the factory could be shown, although that was perhaps sufficient to suggest its actual size. To make the situation quite clear, however, the bird's-eye view which appears below may be of assistance.

To meet the demand for a non-skid tread the Shawmut Tire Company has brought out its "X-tra Tread," in which a raised design is molded into the tread layer of rubber. The design consists of circumferential rows of projections of a six-pointed star shape. The rows are so arranged that the stars in one row alternate with those of the rows on each side. This tread offers to the road surface a great number of sharp points, giving the maximum resistance to skidding, but at the same time the points do not bear the weight of the car, and so do not easily wear off.

Another New England product is the "Eagle" exhaust whistle, made by the Eagle Whistle Company, of Somerville, Mass. It is one of the types designed to be attached at the rear end of the muffler, having an opening through which the exhaust normally passes freely. By means of a pedal on the footboard this opening may be closed, diverting the stream of exhaust gases through the whistle proper. The outfit is simple in construction, having no hidden bolts or screws, and no internal parts which could clog up with carbon or mud. The "Eagle" is made in three sizes, suitable for any size of car, and sells at a moderate price, with the foot pedal and connections included. As a simple and effective, though inexpensive, signaling device it can be highly recommended.

On November 4, the Dover Stamping & Mfg. Co., of Cambridge, Mass., advertised for a name for a new gasoline funnel. The company considered that the funnel was too thoroughly good to have to do with an ordinary make, and it was decided to open up competition and to pay $50 to anyone who would suggest a suitable name for the funnel. The award has finally been made to C. E. Van Bibber, 256 Aspinwall avenue, Brookline, Mass., for the name "Saval." A total of 1,250 letters came from all parts of the country, but none of the other names suggested offered any of the attractions which will be noted as self-evident as the one finally decided upon.



Name Plate of the New Dover Funnel

The funnel in question has a ball check-valve which is normally closed, but opens when the funnel is resting in the filling hole of the tank. When the tank is full, simply lifting the funnel out will close the valve, and the excess gasoline which may be in the funnel will be saved, instead of running over the seat and floor. Thus the description in its name is appropriate.

Shawmut Non-skid Tire

Factory at Watertown, Mass., Where Shawmut Tires Are Made, Together with Hood Rubber Products

CONCRETE CONSTRUCTION ADVANCING IN USEFULNESS

PORTABLE structures were used up to recent times in a temporary way by contractors, sportsmen, and for camping out parties with excellent success, due to the weather-proof qualities of the houses so made, and to the further fact that they were relatively inexpensive, which desirable condition was the direct result of building in quantity. This portable idea has been extended somewhat, and from time to time improvements were made in the quality of the buildings, until today it is proper to say of them that they are portable in so far as they are made in quantity by companies of standing, and in such a way that they may be shipped to distant points, erected into place, and assume all the proportions of permanence.

The earlier types of buildings of this character were a combination of wood framing and corrugated steel, sides, ends, and roofing. They were rather unpretentious looking affairs, and the corrugated steel, despite its galvanized coating, and red paint, rusted out so persistently that three years was looked upon as a fairly good lasting time for the material. More substantial types of portable houses were made of wood throughout, and in them architectural beauty frequently played an important part. These wooden houses added marvelously to the portable idea, and when the automobile became a factor in every-day life, owners of cars utilized portable houses adjacent to their residences to an increasing extent.

The fire risk, especially in cities, is sufficiently great to demand that private garages be given more than ordinary consideration especially when they are placed within 40 feet of residence properties, many of which being wooden structures. It is on this account, perhaps, that the reinforced concrete private garage becomes the subject of great importance, and the manufacturers of portable houses, understanding perfectly the advantage to be derived, are busying themselves in the production of reinforced concrete buildings of the character which can be shipped from the maker's plant to the place of erection.

The illustration here offered is of just such a building, and it attracted considerable attention at the late Boston Show, where it was exhibited by the David Craig Company, 68 and 70 Broad street, Boston, a brief description of which is as follows:

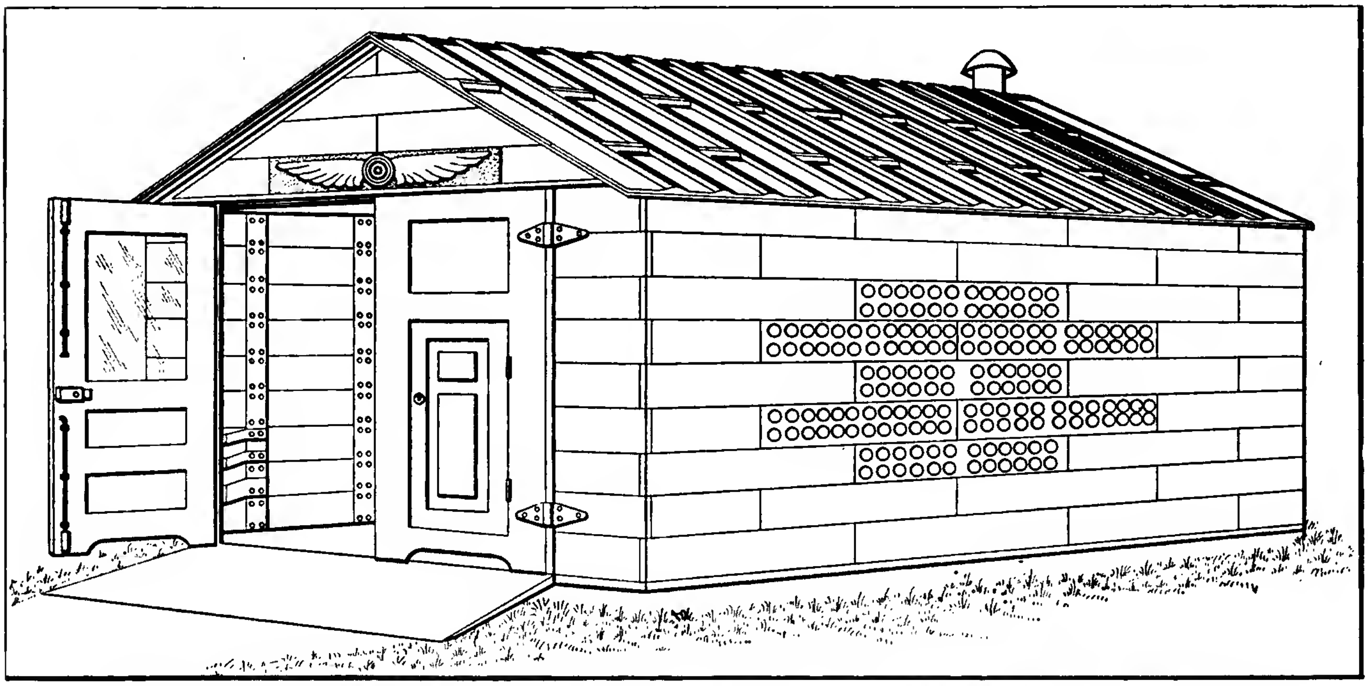
The walls are made of reinforced concrete slabs in sizes of 5 ft. by 1 ft. and 2 ft. 6 in. by 1 ft. and 1 1-2 in. in thickness. The frames are made of steel. The concrete slabs are bolted to the frame with lag screws. The only tool required to erect this garage is a monkey wrench, as they are all manufactured at the company's plant and shipped out ready for erecting.

The company claim a great improvement over the ordinary concrete block construction, as their slabs can be made with a much larger face size, and still not weigh too much for one man to handle, while the size of face gives the appearance of solid freestone. The roof frame is also of steel and covered with either copper, asbestos or corrugated galvanized iron.

Among the advantages which are represented in this structure is the method of inserting glass covered port holes in the side walls for purposes of illumination, and in this way, the disadvantages of windows are eliminated, the building becomes substantially burglar proof, and the light is distributed much more efficaciously than would be possible with a limited number of windows, while at the same time, the fire-proof idea is more definitely incorporated.

The autoist who has struggled with the small garage idea will fully understand how difficult it is to throw light onto the floor, especially under and around the car, if the car itself stands within 30 to 40 inches of the side walls. The series of ports shown in the illustration may be placed quite low down, and there may be as many of them as the autoist might elect to have, so that if the garage is barely large enough to comfortably hold a car, the floor can be adequately lighted by the simple expedient of placing an increased number of these glass bull's-eyes sufficiently low down to throw light upon the concrete floor.

In the erection of a structure as here illustrated, the most desirable results will follow if a substantial concrete foundation and floor are put down, having in mind the fact that good drainage is important, and considering the location and piping from the gasoline storage tank, which, of course, will have to be buried beneath the surface outside the building. The concrete floor would scarcely have to be more than 5 inches thick, and a bed of cinder will properly serve, if the thickness is somewhat over 5 inches. The surface of the floor should terminate in a finish of substantially neat cement.



Concrete Construction Portable Garage Which Was Exhibited at the Boston Show and Attracted Considerable Notice

R.A.C. MAKES PERFORMANCE TEST OF AUTOMOBILES

THE Royal Automobile Club of Great Britain seems to serve its members in certain particulars to a very satisfactory degree, and as an illustration of one of the club undertakings, a certificate of performance, which 'is numbered 184, is here given. This certificate was awarded to a 38.7 horsepower (R. A. C. rating) Napier car, after a test which was conducted under date of February 9, 1910. The motor of this car has six cylinders, with a bore and stroke of 4 and .5 inches respectively. The total weight of the car is 3,574 pounds, distributed as follows: front axle 1,714 pounds, and rear axle 1,860 pounds. The live load was found to be 489 pounds, so that the total running weight as certified to was 4,063 pounds.

The wind resistance area was 13.3 square feet, with a side entrance touring body. The road trial was over a route which is described to include Elwell, Reigate, Westorham, Crawley, Horsham and Brooklands. There were no involuntary stops recorded during this run, and the gasoline consumption was 5.28 Imperial gallons, making the fuel consumption 19.93 miles per gallon, or 36.15 ton miles per gallon.

The track test was for a distance of 13.8 miles, and the highest speed recorded was 61.12 miles with an average speed of 60.14 miles. The fuel economy under these conditions was 12.10 miles per gallon, or 21.95 ton miles per gallon.

ACCELERATION TEST ON LEVEL

Speed attained	Time in which speed is attained from rest	Distance in which speed is attained from rest
10 miles per hr	1.5 seconds	4.8 yards
15 " " "	2.8 "	13.2 "
20 " " "	4.4 "	27.0 "
25 " " "	6.5 "	49.6 "
30 " " "	8.75 "	80.0 "
35 " " "	11.75 "	129.5 "

Average acceleration for 151.56 yards, 5.38 ft. per sec.

A subsequent hill-climbing test, with a measured grade of 1 in 5.027, and a running weight as before stated, showed a speed on this grade of 14.822 miles per hour. The length of the hill was 117 yards, 1 foot, 3 inches, and the grade variations within this length were 105 feet, with a grade of 1 in. 8; 91 feet with a grade of 1 in 5, and 150 feet with a grade of 1 in 4. The test was conducted and declared official under the directions of the R. A. C. Committee, of which J. B. Orde is secretary; Francis W. Teck, chairman; Mervyn O'Gorman, chairman of Technical Committee.

It will be observed that this is test No. 184 which permits one to infer that the R. A. C. considers this class of undertaking as regular and of importance. It should be extremely valuable to makers of automobiles to be able to have models tested out by experienced men under official and open condition.

AMONG THE LATEST ACCESSORIES

(*Continued from page* 600.)

operated by a foot pedal, and the effort of the motorist is accumulated in a spring, and utilized through the ability of a flywheel involving a suitable mechanism as shown.

Non-skid devices for use with pneumatic tires have been found by experience to be thoroughly capable in every way, and, contrary to the predictions of the inexperienced, the chains do not destroy the tread of the tire, but they do prevent skidding and the tire depreciation and other dangers which are imminent when skidding occurs. Fig. C shows the Walker anti-skidding chain which was exhibited at the Albany show, and attracted much favorable comment from the visiting audience. The ring bolts which serve as tie points for the diagonal chain members, are claimed to be particularly efficacious, hence, serve a double purpose, i. e. (a) as a capable mechanical fastening for the diagonal chain members, (b) as non-skid elements.

The Universal Demountable Rim, as depicted in Fig. D, is shown in the position of dissembling, in which a diagonally parted clincher rim is taken advantage of. This rim is of the class which may be expanded in order that it will slip into place over the auxiliary rim of the felloe, and in demounting the rim may be expanded so that it will readily part from the auxiliary rim and come away without having to be jolted with a hammer. A single tool is employed in the locking process, and a latch, which is U shaped, snaps into place across centers.

Lubrication continues to be one of the most important subjects in connection with the operation of an automobile, and taking the problem as a whole, it is more important to have a positive and sufficient means mechanically, than it is to worry about the incidental differences in the respective qualities of the lubricants available for use. This should not be taken as an inference to the effect that the quality of the lubricating oil may be disregarded, but it does lay stress upon the desirability of providing a definite controllable means of lubrication. Fig. E shows a series of Maxwell-Briscoe mechanical oilers being tried out at the works of the company, and it is claimed by the maker, that they have solved the problems of oiling to such an extent that lubricant is fed to the respective journals sufficiently to assure the good which comes from profuse lubrication, so that smoking and other ills are obviated.

MAKING A DEMONSTRATION

(*Continued from page* 601)

inder models of automobiles, and from the best information at hand, it seems that the new sloping bonnet idea, as presented at shows this year, makes a most favorable impression.

(C) Shows how a 1906 Peerless model, after it served in touring work for a considerable time, was converted into a delivery wagon, and is now used in commercial work for rapid, rather than heavy service. The body, which is of the enclosed delivery type, was especially designed for a florist, and reports which emanate from the user of the car are to the effect that it is a distinctly advantageous proposition.

(D) Presents a Reo car which was converted into a livestock express by Theodore Buchneau of Brooklyn, Iowa, and, as shown, it made 28 miles to market with two hogs and 17 shotes, the total weight being 700 pounds. This is the Reo "20," which is a 2-cylinder touring car with a detachable tonneau, which makes it convenient to substitute crates or merchandise.

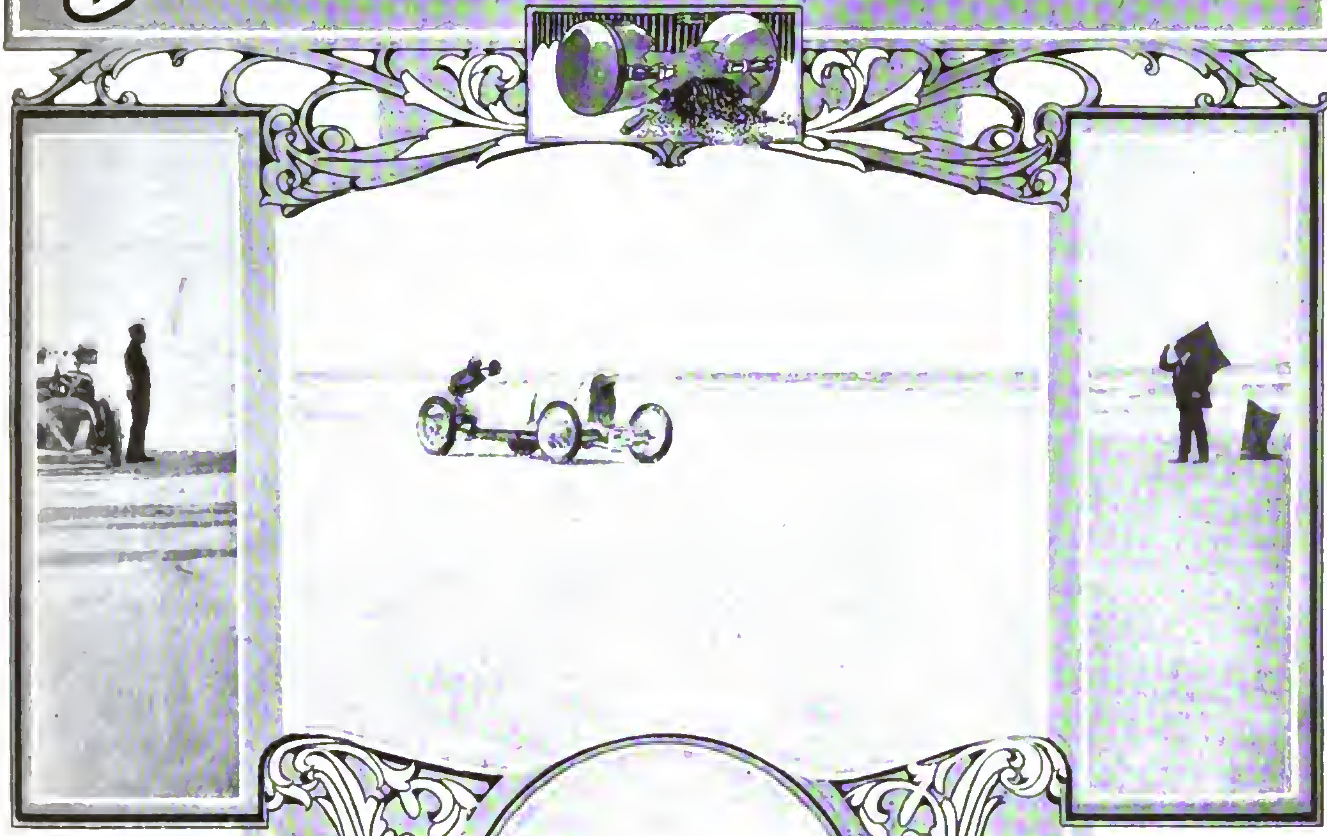
THE AUTOMOBILE



PUTTING a theory into practice is the process which is being employed in the building of automobiles, and the simplicity of the theory, considering surface indications, is at the bottom of many ill-advised attempts. It seems a simple process to apply a motor to a vehicle, and experience seems to indicate that success will attend the effort to whatever extent simplicity serves as the guide. Failure seems to be the product of a series of complex relations, and it is because innovations are too numerous, as a rule, that the results fall far below the usually sanguine expectations.

The best illustration of the good which is derived from the most simple method, will be found in racing automobiles, taking them as a whole. When a contest is to be entered into, the makers of the contesting cars exercise all their ingenuity in the direction of absolute simplicity, and they eliminate every possible construction element in the makeup of their respective products, for no other purpose than to induce stability, engender speed and pare chances down to the lowest possible level.

Were it an easy matter to reduce a theory to practice, racing automobiles would be limited to their performance for the gratification of sports, whereas the sporting phase of the true racing situation is a mere incident. The benefits derived are manifold when a car performs under speed conditions, if the designers watch the performance closely, and take advantage of the knowledge gained.

With the opening of the racing season at Daytona, Florida, on March 23, the attention of the autoing public was again called to this phase of the industry, and those who had occasion to note performances will have observed that new speed records were made, and for the purpose of showing that speed has steadily increased from year to year, tabulations were made and are offered, which will tell at a glance the growth of the automobile industry as it is reflected by increases in the attainable speed of the cars made for that specific purpose.

It is very likely true that the growth of the industry is directly reflected by these very increases in speed, just as the hands on a clock, when they point to the figures of time, offer evidences of the quality of the machinery which controls them. Road performance, under speed conditions, will be good or ill, depending upon the character of the design of the performing automobile, and engineers in attempting to solve commercial problems are enabled to place proper limits upon the design of the component units and parts of the cars they make, with far greater certainty when endurance tests are made.

In the abstract, the diameter of road wheels should be relatively large, so it is said, and in certain classes of vehicles, notably those which travel slowly and bear heavy burdens, the proof seems to be at hand, and the wheels are made relatively

large. Racing cars, on the other hand, if their performance is to be taken advantage of, would seem to indicate that there is a limit to be placed upon the diameters of road wheels. The centrifugal force, which induces fiber strains in the tires and elsewhere in the rotating mass, is increased enormously, and a limit must be placed thereon accordingly.

Racing conditions developed the weakness of these inferior designs, and the weight of motors decreased from the enormous figure of 50 pounds per horsepower, down to approximately 8 pounds per horsepower in the highly developed racing types of motors, and to substantially 17 pounds per horsepower in the type of motors as used in average pleasure types of automobiles. It has not yet been decided as to whether or not the motors used in every-day work should be much lighter than they are, but engineers are somewhat divided in their opinions, some of whom claim that the lighter the weight of the moving mass, especially if it belongs to the reciprocating members, the better will be the result commercially; other engineers call attention to the lack of rigidity of the parts which are reduced, as in racing practice, and prefer to take a medium course.

Conservatism is an excellent virtue, but this same attribute, were it the sole guide, would have defeated the automobile. Motors would weigh at least 50 pounds per horsepower, in the absence of racing and equivalent experience, and conservatism cries out against racing. It may be too conservative to say that the limit has been reached, from the point of view of available power per pound of metal used, but this question will never be answered excepting by trial under severe conditions, and certainly there is no better way to subject an automobile to an abuse test than to enter it into a speed contest.

The life of a machine which has to serve under kinetic conditions will be long or short, depending upon speed more than upon anything else, and, as experience seems to show, there is no way by which quality can be increased in the same ratio that ability is demanded with increasing speed. If the speed of an automobile is doubled, the stresses which will be set up in the component parts will be quadrupled, and an axle, for illustration, which might be quite satisfactory at 30 miles per hour, would have to work 4 times as hard at 60 miles per hour, and 16 times as hard at 120 miles per hour. Fig. 1 shows the front axle of the 200 horsepower Benz car, and attention is called to the enormous mass of metal which was used. The average

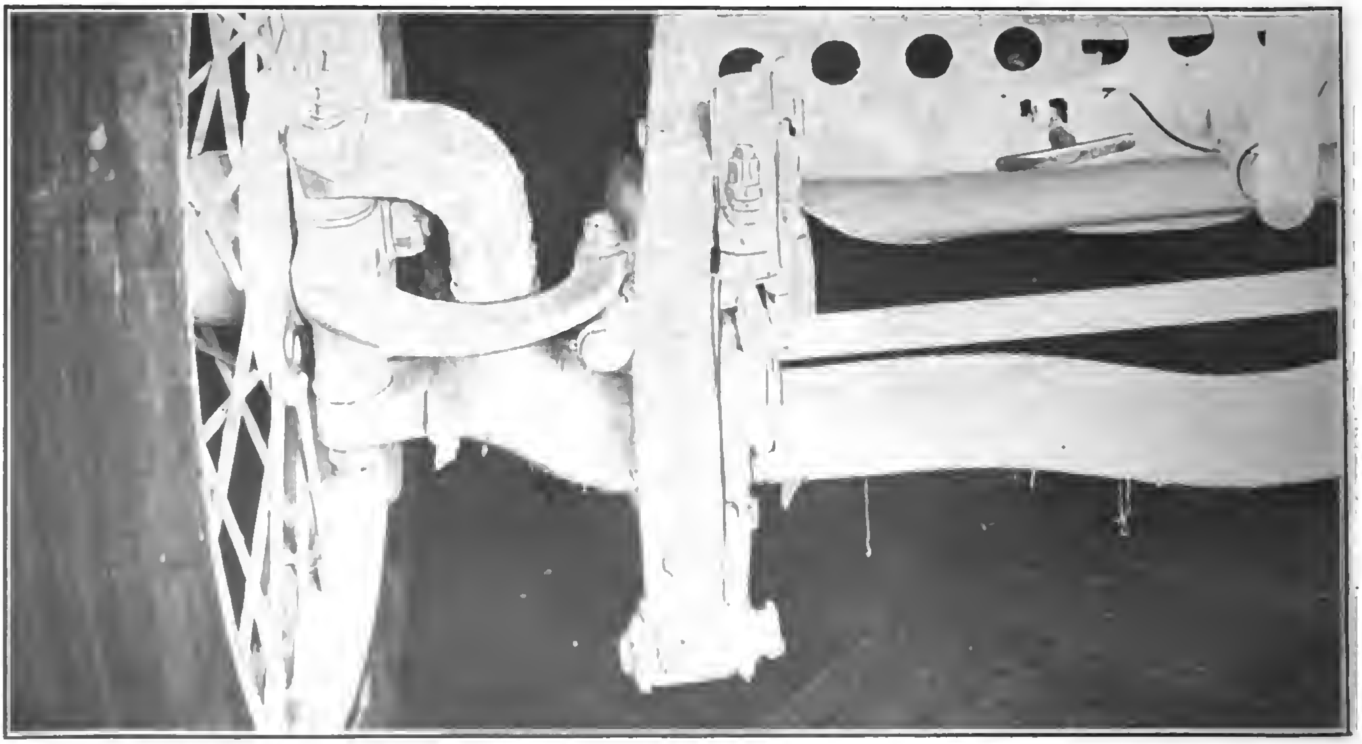

Fig. 1—Front axle construction of the huge Benz racer, which made such a success of racing on the sands at Daytona

automobile enthusiast would naturally expect that the axles and other parts of racing cars should be light, whereas this axle, if it is properly designed, proves to the contrary. That the axle is a nearer approach to correct design than relatively light axles, is proved by the large number of axles which have failed under racing conditions, and some of them were relatively heavy. The simple statement of the law, as above set down, together with the trend in matters of design, goes to show that the reverse to what most people believe is true, and it is in racing work that fallacies are uncovered and facts laid bare. Fig. 2 of the same car shows the rear axle, and attention is called to its perfect symmetry of design, and the secure manner in which it is attached to the side bars, through the springs and the perches.

No form of testing equipment has ever been devised which will determine as to the competence of a motor, under road conditions, from tests made on the "block." There are divers almost insurmountable difficulties attending a block test, which defeat the aim. A motor, to deliver its maximum power, must be tested under conditions which will not harness it down to a series of variable quantities, as when the motor is placed to propel an automobile on the road.

It is the road test which finally settles as to the capability of a motor, and which enables the designer to interject a measure of harmony into the relations. It will not be possible to arrive at the same result by theoretical deduction, nor is the approximation of a theory a reasonable approach to the realization in fact. Motors may be capable of delivering all the power required to drive an automobile at some predetermined and desired speed, but they may not be capable of doing so under the conditions which will govern them under practical working conditions.

Whether or not the new basis for future profit, due to racing, will come this year, it is difficult to predict, but this is no reason why racing should be abandoned, nor will it be proper to justify future activity on the ground that sport demands it. It is not believed that sports will support the automobile industry, and they are one of the effects rather than the pressure on the lever. In the meantime the makers of automobiles will probably continue their effective work, and subject their new models to the strenuous effort which is involved under extreme racing conditions, rather with the hope, perhaps, that something out of the ordinary will come out of it, but with the assurance, in any event, that the weak point will be developed, and a cure effected.

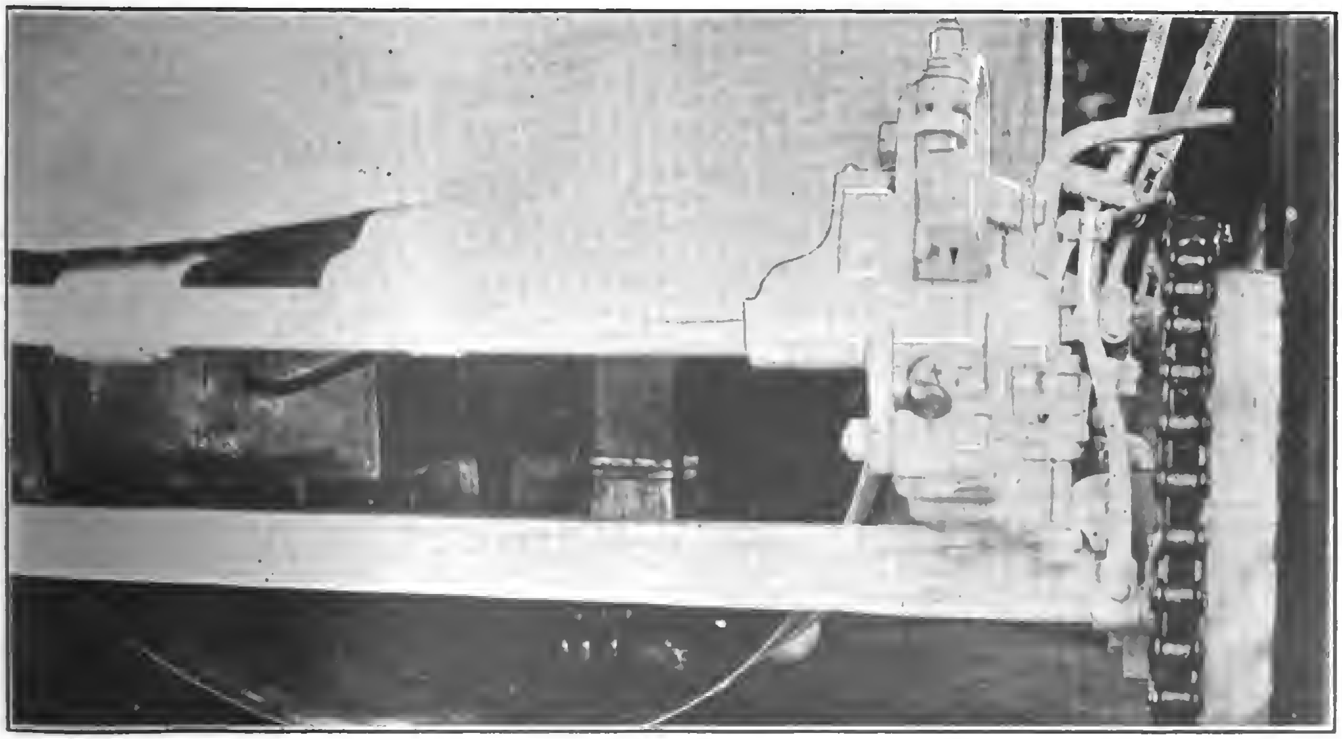

Fig. 2—Rear axle of the same car, showing I-section forging, shock absorber, spring suspension, and chain drive

Matheson Automobile Company, 1888 Broadway, New York City

Factory, Wilkesbarre, Pa.

Motor, six-cylinder, 4 1-2 by 5 inches; cylinders cast in pairs, with all valves in the head on longitudinal axis, interchangeable.

Cylinders are offset 3-4 inch.

Firing order, 1-4-2-6-3-5.

Pistons are 5 3-4 inches long, 0.010 inch small above first ring, 0.005 inch small below; piston pin 1 1-4 inch diameter, with 5-8-inch hole; connecting rods, 10 inches center to center.

Crankshaft drop-forged of 40-carbon steel, heat-treated, with four nickel-babbitt bearings; crank pins 1 7-8 inch diameter, main journals 2 inches diameter.

Flywheel 18 inches diameter by 5 inches face.

Ignition double; Bosch high-tension magneto and storage battery, with six-unit Connecticut coil, completely independent.

Carbureter, Stromberg. Gasoline tank in rear, pressure feed.

Constant level splash lubrication with gear pump and tell-tale on dash.

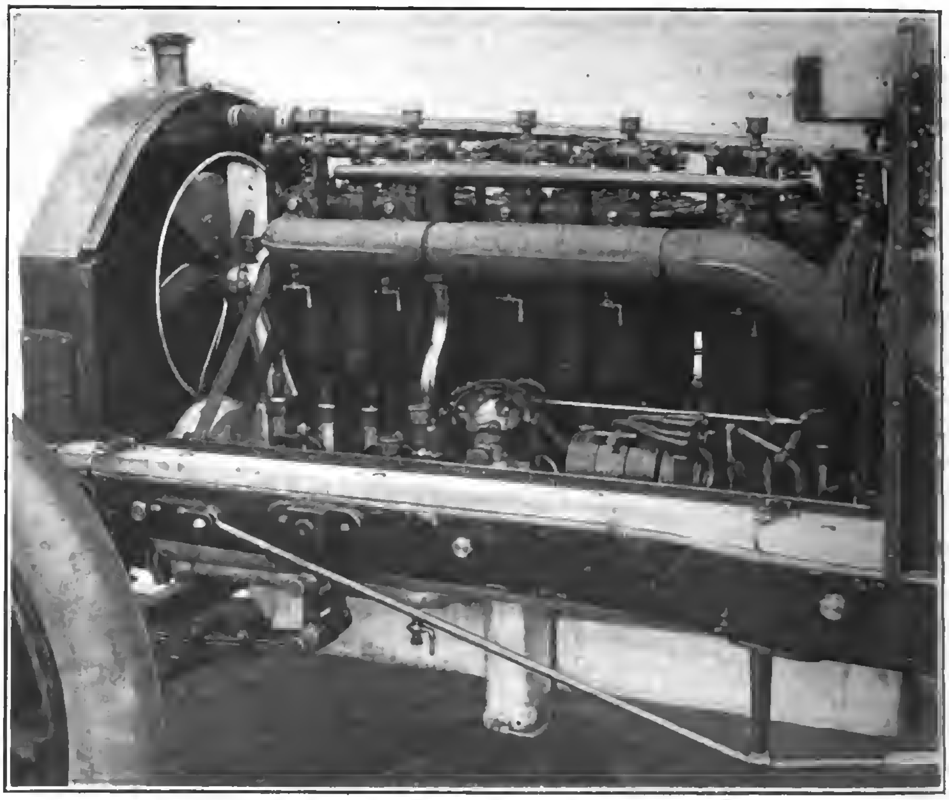
Cooling by honeycomb radiator with 16-inch belt-driven fan and centrifugal pump.

Multiple-disc clutch; 51 steel discs, 10 inches outside, 9 inches inside diameter; 180-pound spring.

Drive by shaft enclosed in torsion tube, with a single joint.

Change-gear on rear axle, selective type, three speeds forward and reverse; gears 6-8 d. p., 7-8-inch face, of nickel steel; Hess-Bright annular bearings.

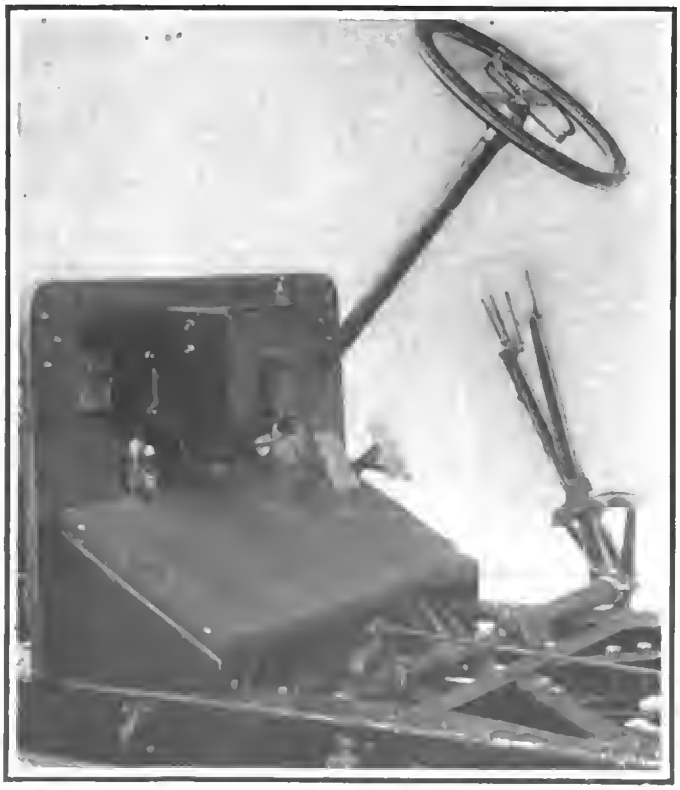
Rear axle of full-floating type; bevel gears 4 d. p., 1 1-2-inch face, 16 teeth into 44, of nickel steel, oil-tempered; live shafts of hammered vanadium-nickel steel, 1 3-8 inch diameter; Hess-Bright and New Departure bearings; bevel pinion thrust transferred to con-



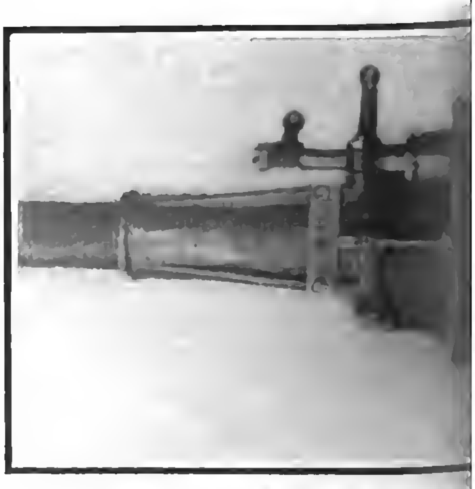
Exhaust Side of the Matheson Motor, with Water and Oil Pumps, Timer and Magneto.

Latest Matheson Six Mechanically Considered

MODEL Eighteen Matheson is the new six-cylinder automobile which is offered by the Matheson Automobile Company, New York City, to 1910 buyers. The touring car is designed to seat five passengers, and the road performance is brought to a high state of perfection, due to the length of the wheel base, which is 125 1-2 inches, and the competence of the tire equipment, which includes 36 by 4-inch tires on the front wheels, and 36 by 4 1-2-inch tires on the rear wheels and other proportions here tabulated. The six-cylinder motor may be described in general as a 4-cycle, water-cooled type, with 4 1-2 by 5-inch bore and stroke of cylinders, respectively, with a company rating of 50 horsepower. The control is effective, and made so by a multiple disc clutch involving the use of 51 discs, and a selective sliding transmission gear, with three speeds forward and reverse, all under suitable control. The weight of the car complete is given as 2,900 pounds, and it is designated by the company as the "Silent Six."

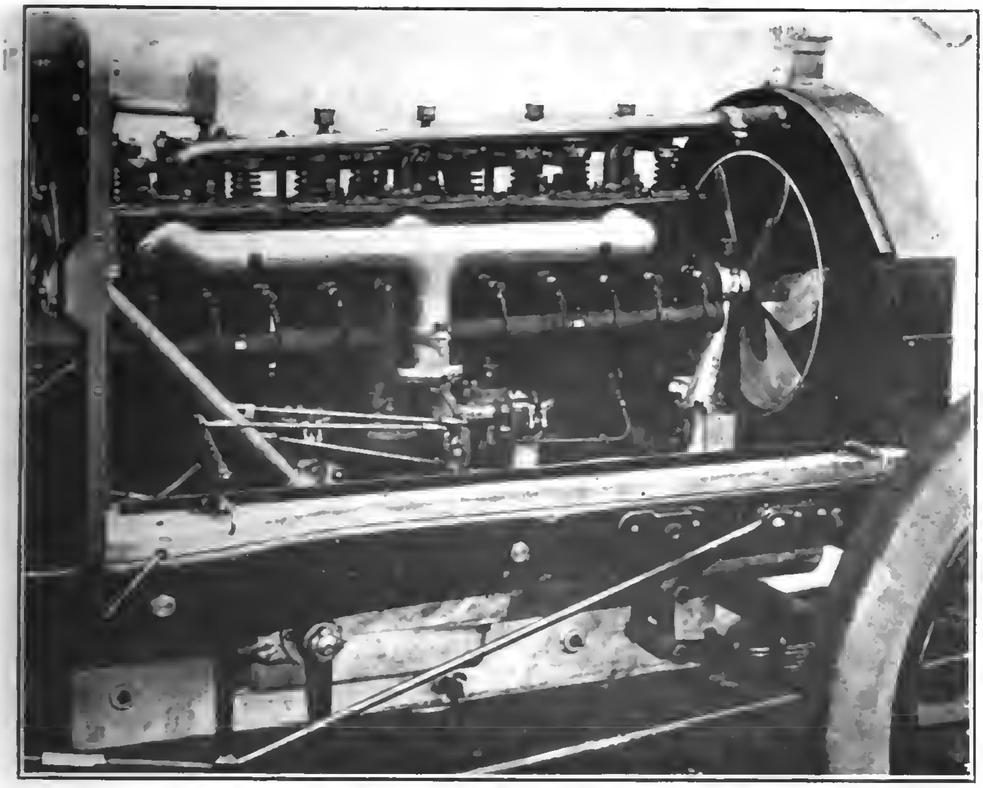


The Dash Carries the Six-Unit Coil and the Oiler Tell-Tale



Neatly Designed Three-Speed Selective Cha[illegible]

Conventional lines of design are closely followed in the motor, the six cylinders being cast in pairs; valves are all in the cylinder heads in a row, actuated by push-rods and rockers from a camshaft enclosed in the crankcase. The actuating parts are made very close to size, with only the minimum clearance, so that they are noiseless in operation without being enclosed or fitted with fiber pads. The cylindrical shape of the combustion chamber allows it to be ground internally, thus assuring uniformity of the explosion impulses of the different cylinders. The



On the Inlet Side Appear the Carbureter and the Conduit for High-Tension Cables

stant-mesh pinion bearing by a single 7-8-inch ball seated axially between ends of shafts.

Brake drums 14 inches diameter, 2 3-4 inch face; internal foot brake and external hand brake; bands and shoes faced with Thermoid.

Front axle made by Timken; weldless drop forging, I-section, 2 1-2 by 1 11-16 inch.

Worm and sector steering gear, ball bearing.

Wheels 36 inches diameter, 10 spokes front, 12 spokes rear. tires 36 by 4 front, 36 by 4 1-2 rear.

Front springs semi-elliptic, 36 by 2 inches, 7 leaves; rear springs full-elliptic, double scroll, 44 by 2 inches, 6 leaves.

Pressed-steel frame, 30 inches wide in front, 34 inches in rear; channel section 5-32-inch gauge, greatest depth 4 1-2 inches, 2 to 4-inch flange; four cross members.

Wheelbase 125 1-2 inches; weight about 2,900 pounds; price with touring body $3,500, including 5 lamps and gas tank.

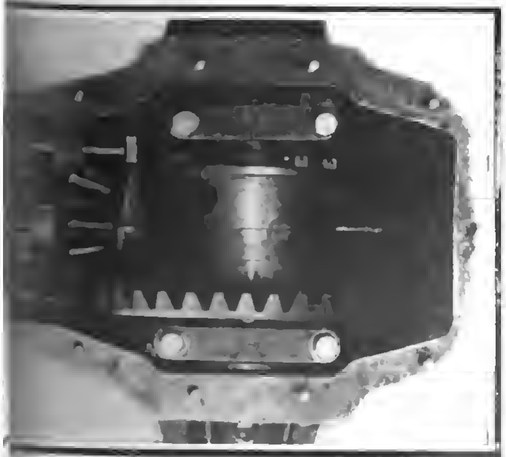
Gasoline tank, capacity 25 gallons, is hung from the rear of the frame, with the front side hollowed out to give clearance to the bevel-gear housing, supported by two steel bands, 1-8 by 1 1-2 inch; tank carries 2 pounds pressure, taken from exhaust, with a pressure gauge and hand pump on dash.

Control: Steering by large hand wheel; spark and throttle levers ratchet-retained on the same sector on top of steering wheel, pulling back to open throttle and advance spark; change-gear by inner side lever, working on H-shaped quadrant; emergency brake by outer hand lever, pulled back to apply brakes; left-hand pedal controls clutch and right-hand pedal the service brake; accelerator pedal to right of brake pedal; cut-out button convenient to left heel.

valves are 2 3-8 inches in diameter, 2 inches in the clear, seated in sleeves ground to shoulders in the cylinder heads.

The base of the motor is an aluminum casting, flanged out to the side members of the frame in such a manner that no under-pan is needed. The lower half is an oil-retainer, and extends back under the flywheel. The crankshaft is carried on four bearings of nickel babbitt; this represents a change from 1909 practice, in which the front bearing was an annular ball type. The photograph shows the completeness of the enclosure. The three-feed mechanical oiler used in 1909 has been replaced by a single gear pump, which maintains a constant level in the crank pits. Oil passes through a tell-tale, allowing the driver to verify the action.

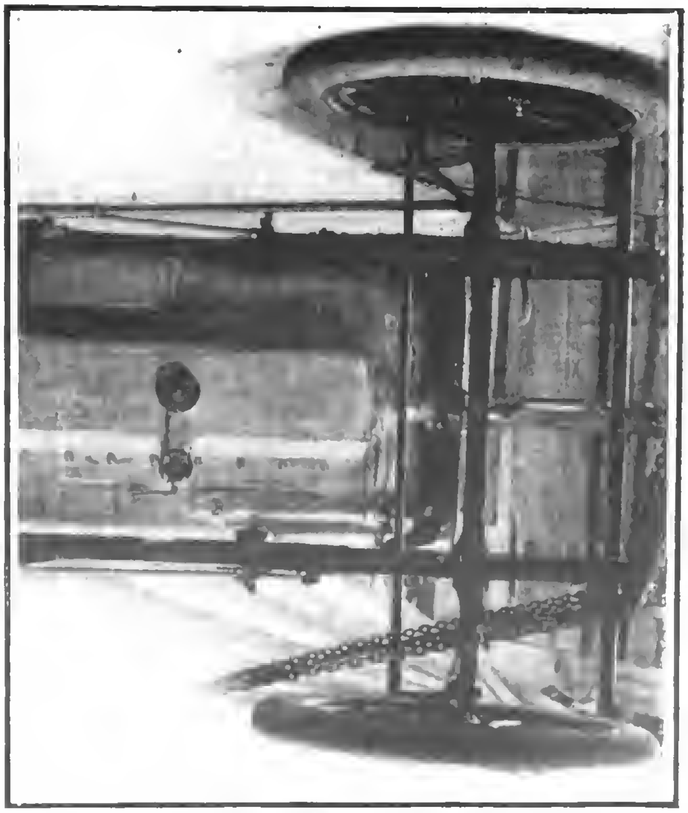
Two independent ignition systems are furnished, including a Bosch magneto, which is located on the left side of the motor, on the pump shaft, and connected by a jaw clutch to allow easy removal. The storage battery auxiliary system works through a six-unit Connecticut coil of a new type in which the units are arranged in two rows of three each, making a very compact box. The systems are entirely separate, each with its own plugs; the high-tension cables are carried through a neat conduit on the right-hand side of the motor.



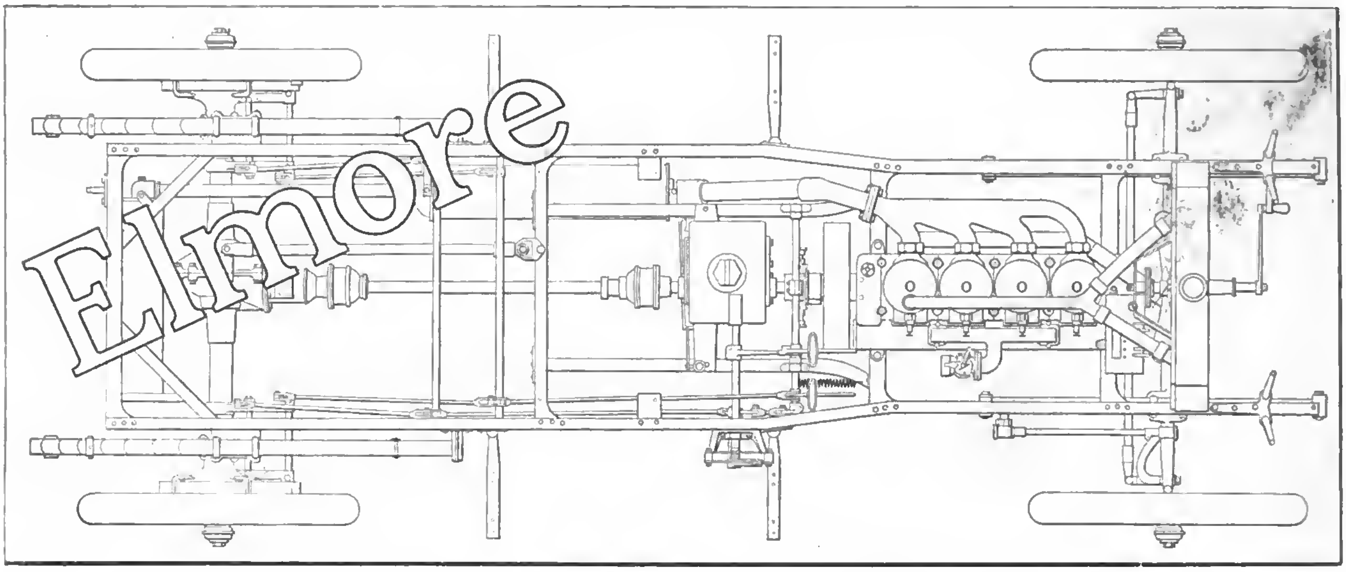
...ked on the Rear Axle, Mounted on Ball Bearings

In performance this Model 18 motor leaves little to be desired. It will run idle at 120 r.p.m. with perfect regularity, the speed being so low that it can be verified by timing the valve-lifts with a stop-watch. The muffler cut-out reveals a regular exhaust. The car runs at 3 miles an hour on the high gear without slipping the clutch, still without vibration, and the only sound audible from the front seat is a faint hum from the transmission mechanism.

Matheson Model 18 in general appearance is striking, with a long and distinctively six-cylinder hood. The mud-guards extend into the frame, with a sheet-metal boot between the frame and the running-board. The touring car and the toy tonneau, seating four, both sell at $3,500. For $4,000, this chassis may be had fitted with a new style torpedo body, while at $4,700, a limousine or landaulet type of enclosed body is available.



Motor Protected Against Dust and Mud Without Separate Pan



View from Above of Chassis of Elmore Model 46, Showing Location of Motor, Transmission and Other Parts

Price, Model 46, touring, $2,500
Weight, equipped, 2,800 pounds

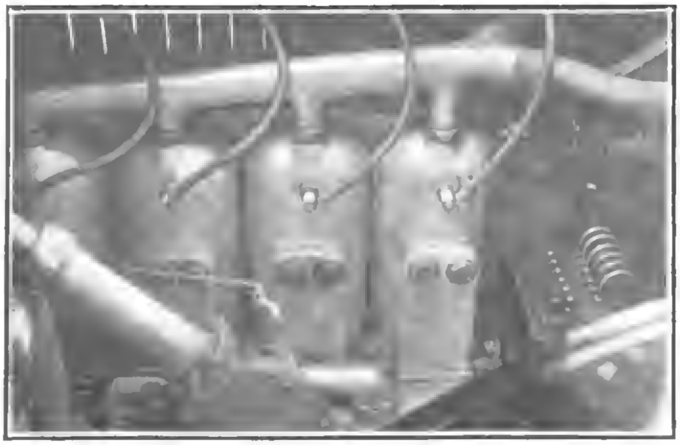
Tires, rear, 36 by 4 in.

Frame, 27-30 carbon pressed steel
Front Axle, I-section, drop-forged high carbon
Rear Axle, semi-floating
Rear Axle Bearings, double ball type
Wheels, artillery type, second growth hickory
Rims, standard universal

CONSIDERING the latest tendencies in automobile circles, no one is more noticeable, widespread, and popular than the double tendency towards simplification and economy, as usually induced by such simplicity. Bearing this prominently in mind, it is not strange that the public has, of late, shown a decided tendency to give the once despised two-cycle motor a chance.

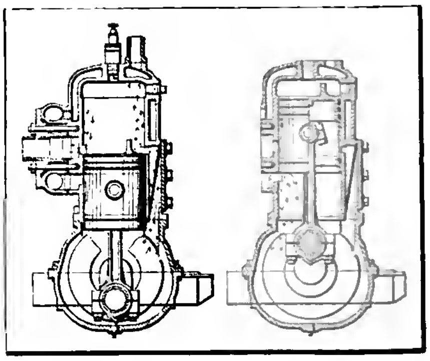
This is resulting in a number of new designs of this type of motor, and others closely allied with it, to say nothing of new and different types, which are, to say the least, getting a fair chance to "make good." Among these may be noted a revival of interest in fuel injection, as first brought out by Diesel, in the differential piston engine, in the use of rotary crankcase inlet valves, of valves within the piston, in the piston head, to be exact, and in many other forms. Some of these differ widely from both the accepted two-cycle and the usual form of four-cycle engine, while some others, in a desire to excel the older types in fuel economy, have turned to a combination in part of the two forms, utilizing some valves, and valve-operating mechanism, while retaining the inherent simplicity of construction and operation of the two-cycle form.

Nor have the older and well-established makers been content to relinquish their advantage, gained by several years' experience, without attempting something slightly out of the ordinary run. To stand aside and allow newcomers to usurp their chosen field would have been a suicidal policy, because each and every one of the newer inventions might have one single feature which would be of such compelling worth as to give the engine prestige and incidentally business, at a bound, so to speak, regardless of the crudities impossible to avoid in the new and untried product of a maker without previous experience



Inlet Side of Elmore High-Duty Engine, Showing Bypass Covers

Among the tried and proven makers in this field of endeavor, no one is better and more widely known than the Elmore Manufacturing Company, of Clyde, O., founded and maintained by the Becker Brothers, up to the recent acquisition of the plant and good will by the General Motors Company. This latter change, it is said, will not result in any radical change in policy, the idea being rather to continue along chosen lines, and expand rapidly on the proven product. Thus, the factory facilities will be increased to such an extent that the output for 1909 of 800 cars will be "boosted" to 2500 for 1910



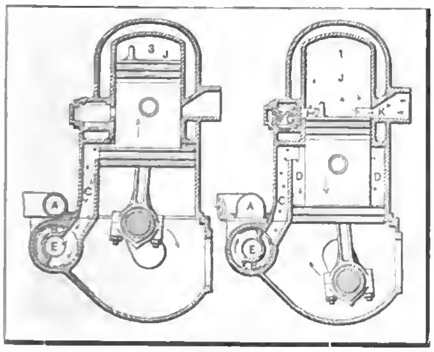
Sections Through Model 36 Engine

This product has been brought right up to date by a slight change in the design of the engine, without, however, changing the bore and stroke, although there are other changes in the construction of the engine. The old engine is also made and used in the lower-priced model, now called Model 36, while the newer engine is only used in the higher-priced car, which is called Model 46, the two names being indicative of the amount of power developed by the two motors.

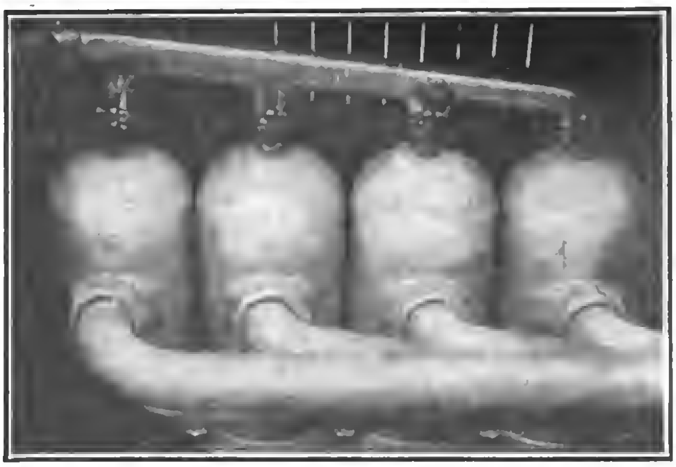
Both are of the four-cylinder, two-cycle, three-port type, but on the higher-powered unit, the differential piston is used. For the benefit of those to whom this nomenclature is strange, it might be stated that this consists of a second and larger diameter for the lower part of the piston, which enlarged diameter works in a cylinder bore of similarly enlarged diameter This latter part of the cylinder bore has a head or top partition of its own, similar to that of the ordinary piston. This enlarged portion is connected to the inlet pipe, which is set low along the right side of the engine, through the medium of a long compartment or by-pass, the lower end of which is opened and closed at the proper time by means of a rotating valve set within the inlet pipe.

This rotating sleeve, for it is more of a sleeve than a valve, is driven off of the crankshaft by means of reduction gearing. In operation, the annular ring, or differential piston, supplies compressed gas to other cylinders, numbers 3 and 4, for instance, compressing gas which flows through into cylinder one's combustion chamber, while the enlarged pistons of 2 and 1 are drawing in and compressing a fresh charge, the shape of the internal part of the distributor sleeve being such as to allow of this. The firing order is 1, 3, 2, and 4, in order from front to rear. Then, considering the operation just described, the next order, after firing cylinder 1, and exhausting from the same, would be cylinders 1 and 2 compressing fresh gas, which would flow through the distributor into the cylinder next in firing order, namely 3. At the same time, the differential pistons of cylinders 3 and 4 are draining in fresh gas.

Getting down to the specific action in any one cylinder, as illustrated by the adjoining small drawing, which shows a section through two cylinders, set side by side, and which are lettered in order to make the operation clear, the incoming gas is drawn into the annular chamber "D" during the entire downward stroke of the piston. The gas passes from the carbureter through the manifold "A" into the distributor "E", then through the distributor port "B" and pump by-pass "C", entirely filling the annular chamber above referred to (Fig. 1). At the same time the gases in chamber "D" (Fig. 3) have been compressed (the crank of this cylinder being on the opposite cycle from Fig. 1), forcing the new gas through by-pass of Fig. 3 into the distributor, which has now changed its position to admit the new gas, and on through port by-pass "F" and ports "H" into the combustion chamber, where, upon being compressed, the gases are ignited and escape through port "K" at the conclusion of the downward stroke of the piston.



Sections of Model 46 Motor

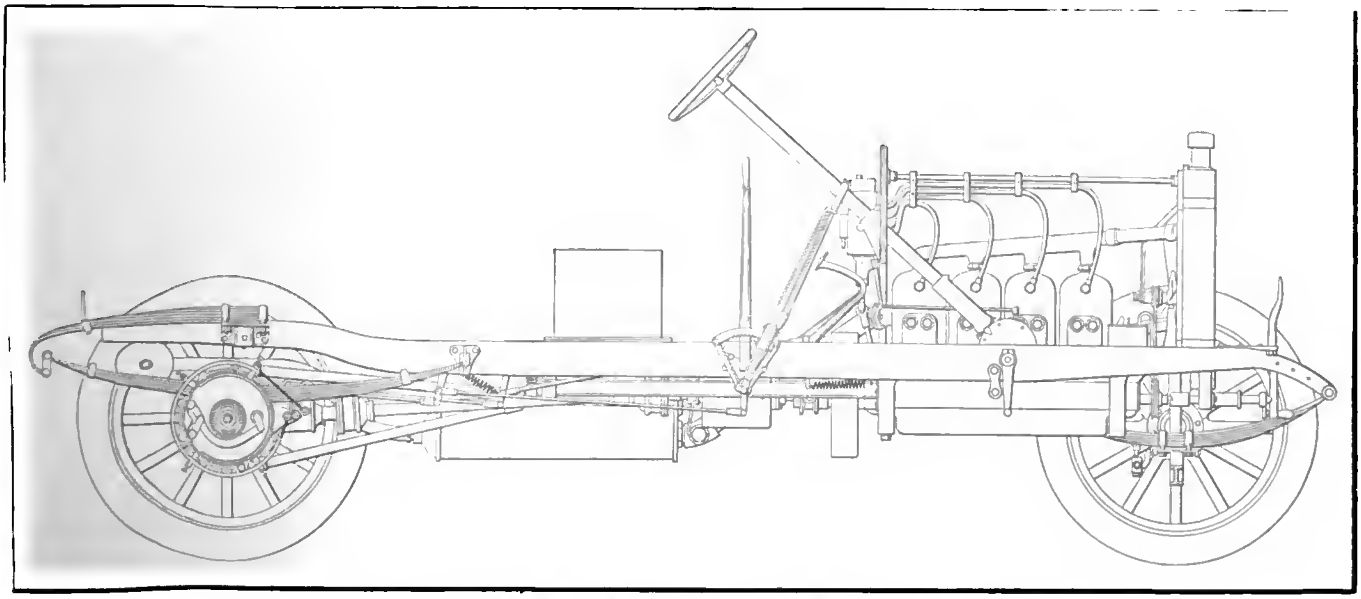


Left Side of High-Duty Motor Showing Exhaust Pipe

There is no intermingling of new and old gas for several reasons. In the first place, there is not time enough; and the escape of the exhaust gas through the port "K" has an ejector effect, creating a tendency to draw in the new gas through a partial vacuum caused by the rapid and complete discharge of the exhaust gas. The incoming gas, through the timing of the inlet port and the shape of the deflector plate on the top of the piston, must first pass to the top of the cylinder, then filling the partial vacuum caused by the exhaust of the exploded gases.

Exhaust in each case is no different from the ordinary case, the port being an opening in the side of the cylinder casting, which, opening the descending piston, uncovers at the proper time. In addition, the deflector on the top of the piston turns the incoming gases upward, away from the outgoing and worthless burned products. In effect, then, the uncertainty of crankcase compression and feeding by guess to the combustion chamber is replaced by exact and determinable compression in a small cylinder for that specific purpose, using a special piston, which compressed product is led accurately into the proper cylinder through a correctly timed rotating valve, mechanically driven. The whole effect should be to make the engine more reliable and efficient in just the proportion that approximations and guesswork are replaced by mechanical certainty.

In Model 36, the older form of engine is retained. This is shown on the page opposite for comparison with the newer type. It has the three ports, the gases being compressed in the crankcase, passing through a by-pass, screened to prevent back-firing.



Side Elevation of Model 46 Chassis, Showing Large Wheels, Springing, and Shape of Frame

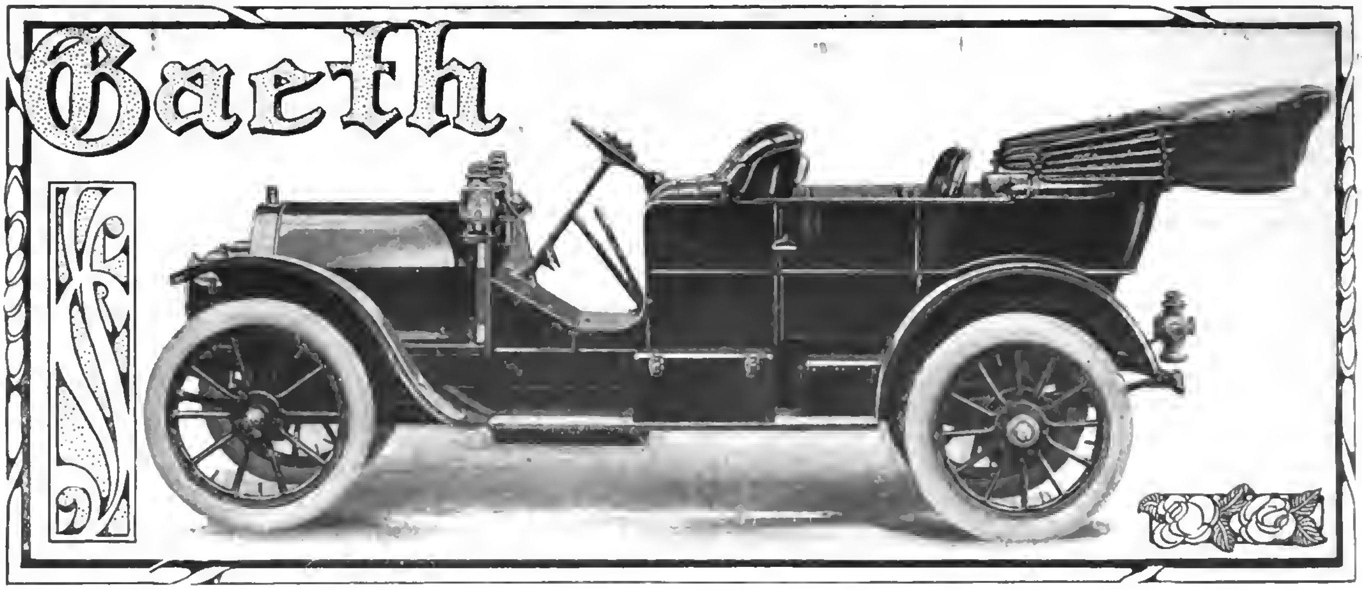


Fig. 1—Gaeth touring car with an attractively designed body following in general the straight-line type, fully equipped

MODEL XXI, 1910 Gaeth, represents a chassis which is normally designed for touring service, and with the side entrance body as presented in the title illustration, it represents characteristic Gaeth construction. Before proceeding with the discussion, involving the power plant and mechanical equipment of the above model, it will be in order to state that the Gaeth Automobile Company, of Cleveland, Ohio, manufactures a commercial type of automobile, in addition to the Model XXI chassis, as used for pleasure automobiles.

The motor, which is used in the Model XXI Gaeth chassis, is shown in Figs. 2 and 3. Referring to Fig. 3, the magneto M_1, which is responsible for the ignition work, is set on a raised surface of the extension of the crankcase (top half) and is driven by a flexibly contrived shaft, which takes its power from the half-time gear system in the housing H_1. The flange F_1, with its overhang H_2, and a similar overhang at the opposite end, butts against the chassis frame, and under pans are not required, because the shape of the crankcase, in view of the flaring extension referred to, renders the system self-contained and tight against foreign matter of any kind whatever.

The ignition system will require a little explanation, in view of a certain ingenuity of construction, involving the make-and-break principle, and in which a vertical shaft S_1, Fig. 2, raises up at the right side of the motor in a mid position between the two pairs of cylinders. The base of this shaft holds a spiral gear, engaging a similar gear attached to the intake valve camshaft, from which power is derived. A means is afforded for sliding the gear on the vertical shaft in the axlewise direction, for the purpose of adjusting the timing relation. A two-piece bronze sleeve is fastened over the camshaft, and bears in a groove in the end of the sliding gear. The spark level on the steering wheel is connected to this sleeve by suitable links and a motion, for the purpose of enabling the driver to suitably advance or retard the spark.

To the top of the vertical shaft S_1, Fig. 2, there is a pair of small cranks, which are related to as many push rods in a horizontal position, which are placed there to trip the contact arm of the igniter. The excellence in point of detail of this ignition system will best be appreciated by observing the character of the work indicated as I_1, Fig. 2, this being one of the vertical post stops

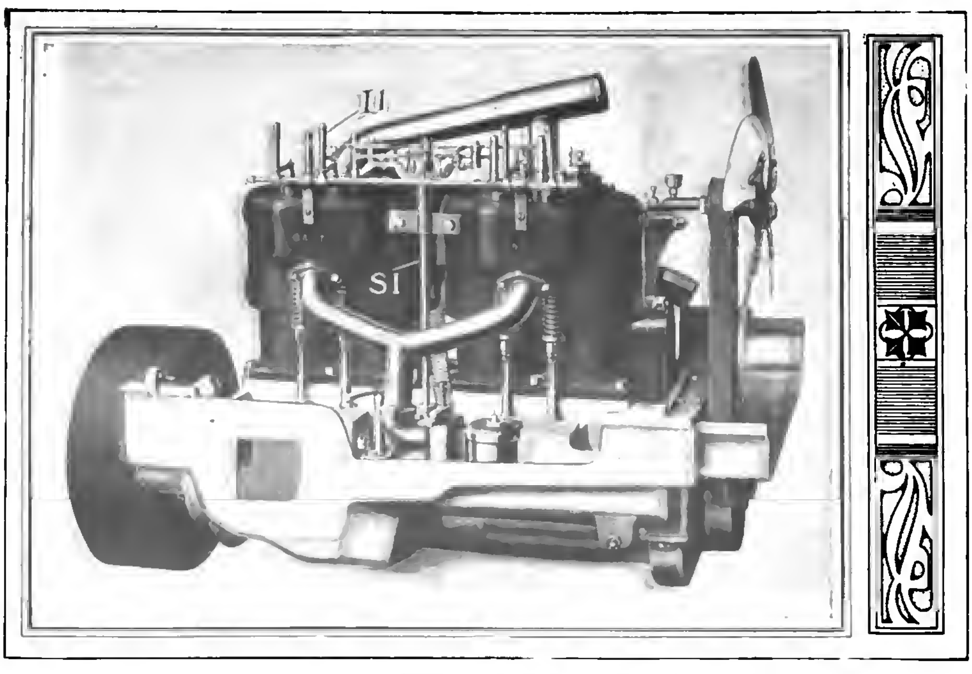

Fig. 3—Make-and-break ignition system actuated by a vertical shaft

The four-cylinder water-jacketed motor of the four-cycle type is of symmetrical design, with the cylinders cast in pairs. The bore is 4 7-8 and the stroke 5 1-4 inches. In the design of the cylinders, particular attention was paid to the water-jacketing, the idea being to allow a sufficient volume of water at every point to assure efficient cooling. The path of the current of water is directed in such a way that each portion of the water is heat-ladened to its maximum ability, and the ills of unequal expansion are avoided. The metal used in the cylinders, pistons and piston rings is a specialized gray iron product, which affords a hard white surface over the cylinder bore, and a close grain in the section with a sufficiently high average strength to indicate competence.

The valves are placed in offset extensions, with the inlet and exhaust on opposite sides T-fashion, and the valve diameters are substantially equal to half the cylinder bore, which condition, together with a properly arranged compression, well-timed ignition and suitable carburetion, is responsible for the tenacity with which the torque holds under conditions of increasing speed, so that the power of the motor increases in direct proportion to speed, up to a high point in the range of performance.

The camshafts, one for each valve system, placed on opposite sides within the crankcase, are supported by three well-designed white metal journals, and with the half-time gears. are completely enclosed. Means for profuse lubrication are provided, and silent performance, which is experienced, is due to:

(A) Accuracy of workmanship.
(B) Muffling effect of the housing.
(C) Precision of adjustment.

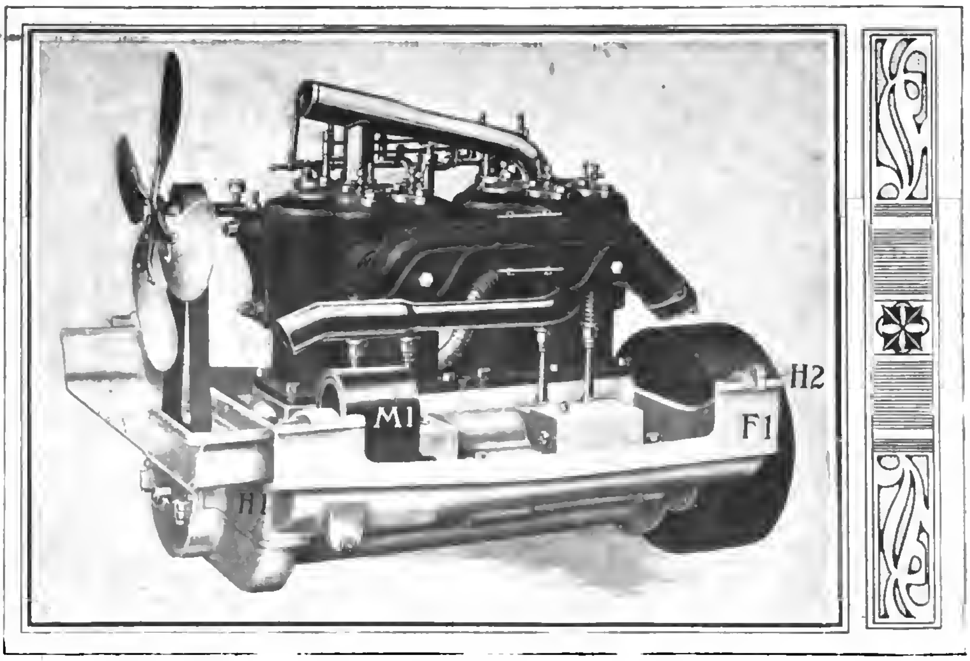

Fig. 3—Large pipes allow natural water circulation, without pump

Much of the good performance of the motor may be traced to the shape of the valves, which, by the way, are the same size for inlet and exhaust, lightweight of the reciprocating mass, and the well-designed valve springs which have life and strength sufficient to compel the roller to hug the cam faces. so that the valves close within the minimum allowable angular distance of travel of the camshaft.

As a further indication of the competence of design of the motor, the connecting rods and pistons may be examined, when it will be found that the pistons are shaped for strength in the absence of undue weight, and the connecting rods are drop forged from a suitable grade of carbon steel, after which they are annealed, thus inducing kinetic qualities, the idea being to make them not only stout, but light, in order that the secondary moments which increase as the speed square, will be so limited that the extreme fiber strain in the shear plane of the most critical point in the crankshaft will be within the allowable limit, taking as a basis the life of the steel. under conditions of diagonal work, remembering that it is but short, if the extreme fiber strain is any great proportion of the elastic limit of the material used.

Aluminum is used for the top and bottom half of the crankcase, transmission gear case, and such other parts as may be produced for the purpose of maintaining the total weight of the car within proper limits without endangering life, which is a matter of properly utilizing aluminum, it being the lighter of the metals with strength sufficient for the work it is placed to do.

In Fig. 4 are to be seen both of the axles, the front with the steering knuckles, and cross-connecting rod, and the rear with brakes, brake operating levers, truss rod, and other parts. The former is of the I shape, now so general, and has a deep drop in the center. The cross-connection, on the other hand, is carried straight across, being placed back of the axle, so as to be protected at all times. The spring pads, for the support and attachment of the springs, are forged integral with the bed. In the axle end construction, a thrust bearing is placed below the upper arm of the axle, thus taking up all heavy load from above.

The rear axle is composite, being of several parts, each best suited as to shape and material to the work to be done, the whole being united into a complete and sturdy unit, by riveting and welding, the spring pads being held on by means of bolts. The brakes are of two kinds, internal expanding and external contracting. The former are separately operated.

There are many other points of mechanical design which are characteristic of the Gaeth engineering office that accord fully with the methods thus far described, and a close study of the illustrations here given will render them at once apparent.

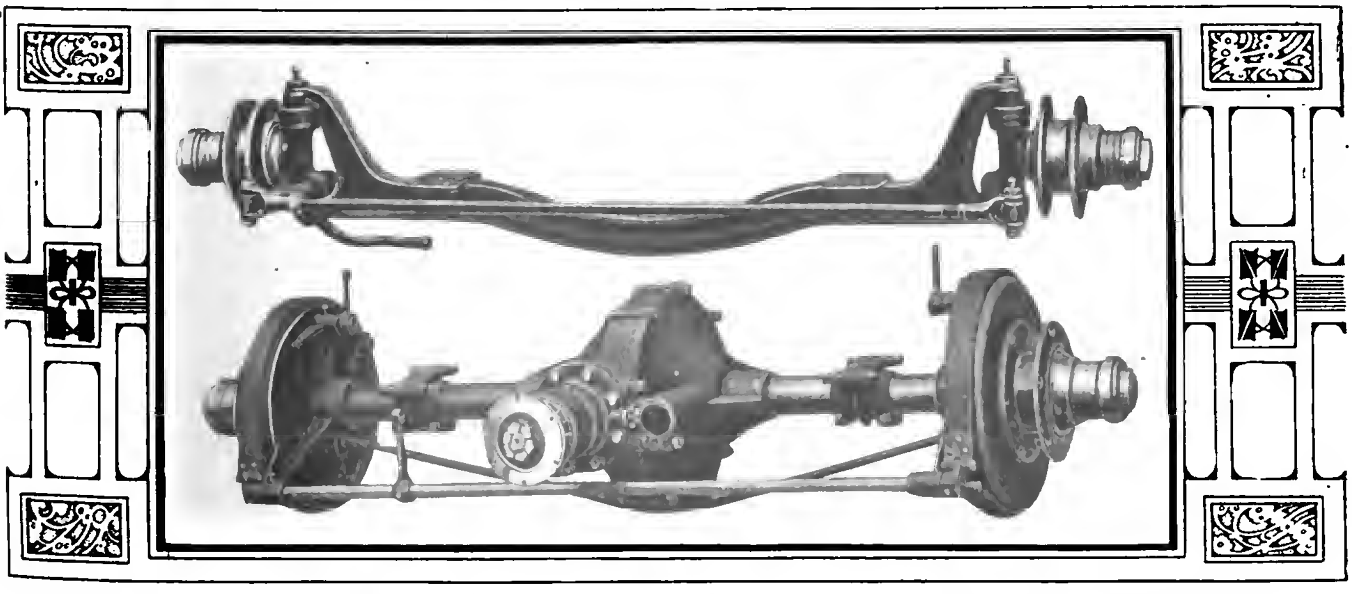

Fig. 4—Front and rear axles, both of standard design; the former an I-section forging, the latter of the floating type.

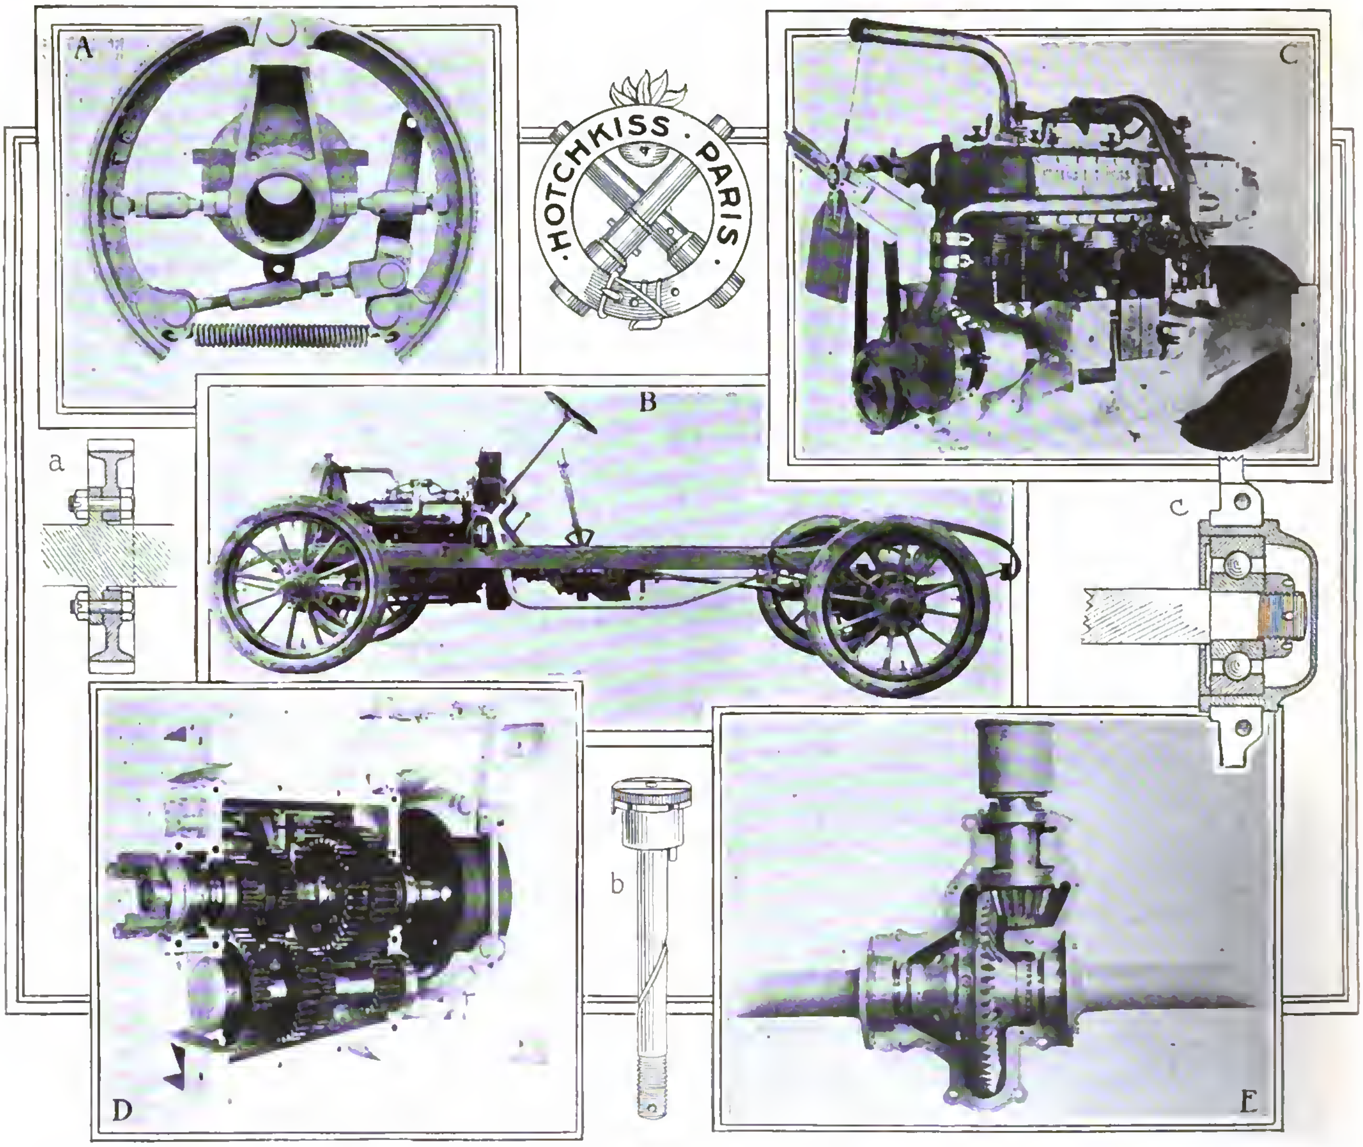

Fig. 1—Model T Hotchkiss showing the chassis side view motor, transmission gear, bevel drive, brake mechanism, and other details

MODEL T Hotchkiss as here mechanically considered, is offered for the purpose of presenting the characteristics of the French school of design, and the illustration *B* in the above group shows the chassis assembled, in which the side bars are of the channel section, with a rear kickup, and three-quarter elliptic springs (scroll type) are placed to absorb the road inequalities and induce a level platform. The general construction of the chassis approaches that which seems to be the trend from the point of view of standardization, and it is in the details in design of the component parts that much of interest will be found if the keen observer looks.

Referring to *A*, which is at the upper left-hand of Fig. 1, the internal expanding brake mechanism shows a stout spring release, which is diametrically the point of hinging of the two shoes, and the spring is prevented from pulling the shoes toward the axis in the radial plane by a pair of adjustable limit stops, which are jacks of the screw type in miniature. Lock nuts are responsible for the permanence of the adjustment of the jacks. When it is desired to apply pressure to the brake drum, motion is imparted to a lever arm, the fulcrum of which is at the terminus of one of the shoes, and a strut, with a turnbuckle to vary its length, engages the arm near the fulcrum, and is connected with the adjacent arm. By means of this adjustable strut, the shoes are expanded, and the distance of travel of the brake arm, for a full engagement of the brakes, may be varied by altering the length of the strut, through the good office of the turnbuckle.

The Model T motor is shown at *C* in the same figure, and among its conspicuous features there are a few which show upon the surface, as the location of the large water pump at the front of the motor case, fastened to the cover of the half-time gear housing, which brings the water intake to the pump within a few inches of the underside of the radiator, when the motor is in its proper position in the chassis, so that the arrangements for cooling are complete and much simplified. The magneto shows on the right side of the motor in a mid-position, and the wiring passes up through a conduit which is shaped for convenience, while the arrangement suggests system and freedom from ignition troubles. The air fan, which is run by a flat belt with a wide-faced flanged pulley at the driving and driven end, has unusually large veins and suggests capability. The cylinders are provided with separable jacket covers, which have three advantages, (a) the castings come from the foundry in a more perfect state, because the gases which are generated during the pouring process are tapped away through the openings thus afforded; (b) the castings may be freed from core sand; (c) in service, if the cooling water is full of sediment, and it forms a crust over the heated surfaces, the covers may be taken off and the crust may be gotten at and removed.

Referring to *E*, the jack shaft, bevel drive and differential gear system are presented, half of the housing being removed for the purpose. The differential gearing is compact, is of the bevel gear system, and the housing is provided with holes, through which grease may circulate for an obvious purpose. The bevel gear, which meshes with the driving pinion, is flanged to the differential housing, and it is conspicuous for its shape. The design of the bevel gear is symmetrical, with uniform thicknesses of metal at every point, and the noiseless performance obtained in practice is due to absence of deformation of the bevel gear during the heat-treating process to which it is subjected to give to it kinetic properties. The driving pinion fetches up on a taper, and a large castellated nut engaging a threaded portion on the end of the propeller shaft assists in forcing the pinion up on the taper and holds it in place. The shaft terminates with the pinion, and two annular types of ball bearings placed just back of the pinion carry the load. The bearings are relatively large, and are spaced far apart so that the tendency of the propeller shaft to float away from the bevel gear is adequately resisted. The shaft terminates in a universal joint just outside of the housing.

The transmission gear is shown at *D*, and the service brake drum is on an extension of the shaft, just outside of the case, and the method of its application is suggested by the arrangement of the links and levers there indicated. The system is selective, with four speeds and reverse, and the gears have wide faces, and are securely placed on shafts of relatively great diameter, considering the distances between bearings, so that shaft deflections are reduced to the infinitesimal increment.

The sketch (a) shows how the gears are flanged and bolted to the shafts, and it is pointed out that the gears are of symmetrical design, with even thicknesses of walls, hence they may be finished and heat-treated with the minimum difficulty, from the point of view of deformation, so that in service undue strains will not be present and noiseless performance will be more nearly assured. Sketch (b) shows a detail which represents the knuckle pin, which is made of a fine grade of alloy steel, is threaded at the lower end, has an integral bowl-shaped enlargement at the upper end, in which a cavity is fastened for the purpose of storing grease, and a compressor top, with a suitable lock, may be screwed down for the purpose of forcing grease into the bore of the pin, thence out through holes, which register with a groove, the latter being shown. Sketch (c) suggests the secure manner of placing the radial ball-bearings which are used in Hotchkiss cars. The bearings are a sucking fit over the spindle, press up to a shoulder and are held in place by castellated nuts. Separate bronze housings are used in conjunction with these bearings, and means are at hand for retaining the non-acid grease which is recommended for use with ball-bearings.

SOME INDICATIONS OF EXCELLENT SERVICE

Fig. 2 presents a group of parts which were taken from a Hotchkiss car and put under seal by the technical committee of the R. A. C. After the car, which was rated at 45-horsepower, traveled 10,000 kilometers in France (6,250 miles) it subsequently entered the English Tour, and made 15,000 miles under the observation of the technical committee of the R. A. C. The photographs were taken with the seals of the R. A. C. intact, and a close inspection of them develops nothing by way of noticeable depreciation or even ordinary wear.

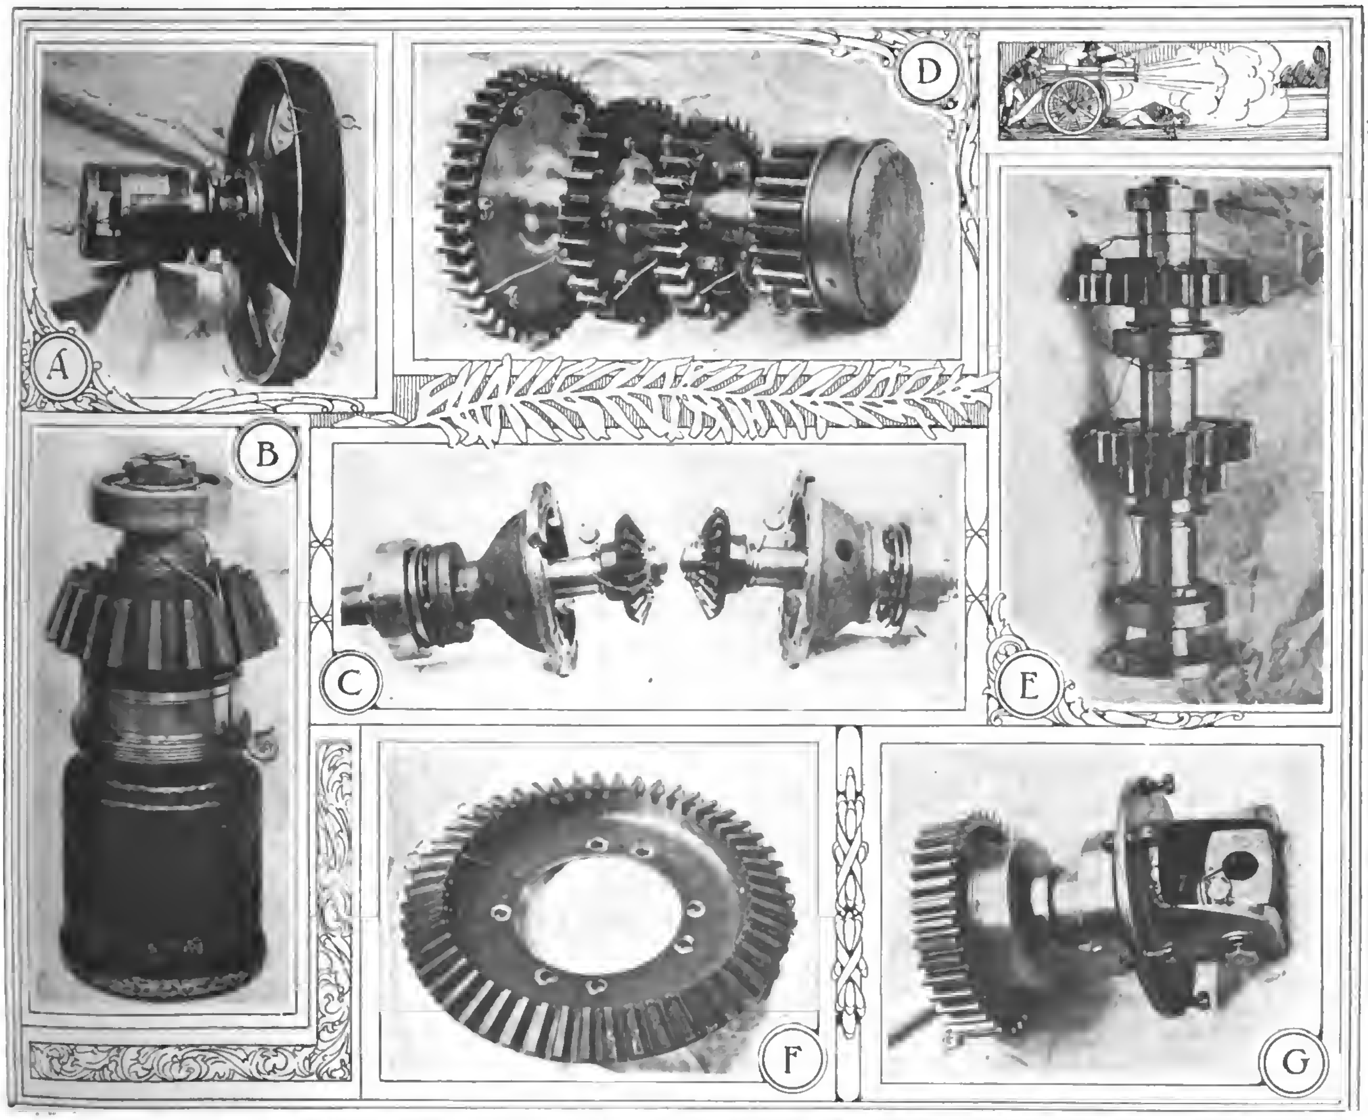

Fig. 2—Transmission gears, bevel gear system, differential set, universal joints and clutch, as taken from a Hotchkiss car, by the R.A.C. Committee after an endurance run, showing the seals in place

Fig. 1—Six-cylinder Napier landau with long wheelbase, excellence of accommodation, ample power, definite control, and class distinction

GLANCING at the title illustration discloses a Napier six-cylinder automobile, in this particular example, fitted with **a landaulet body, which is selected to accentuate the characteristics** of Napier cars from the point of view of appearance and accommodation. It will be observed that the wheelbase is sufficiently long, not only to afford room for a six-cylinder motor, but to include a wide side entrance in the body design, and at the same time leave for the driver's accommodation a full-sized seat and ample foot room.

It is distinctly in the path of wisdom to make the wheel base such as to permit of utilizing a motor, if of the six-cylinder type, which will not be cramped in point of design for no better purpose than to save room, and the side entrance of the body must of necessity be wide. It is an excellent idea so to place the door that it will swing open in the forward direction. In this design the door is far enough towards the front of the car to clear the rear mudguards. It is also advantageous to allow the standard proportions for the driver's seat, and the regular amount of foot room, thus permitting him to assume an easy and natural position.

The Napier six-cylinder motors are made as follows:

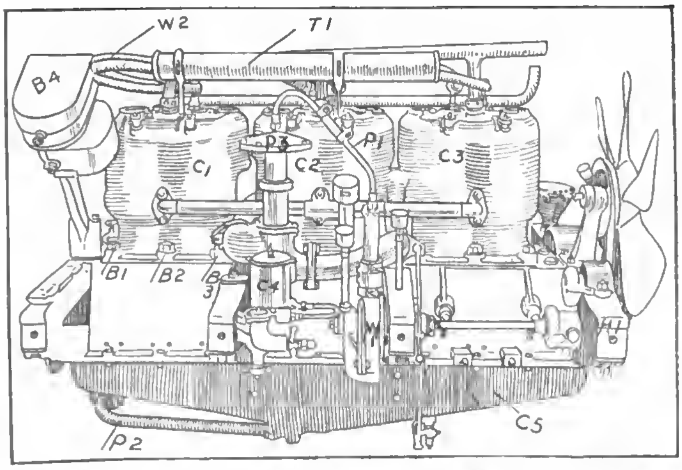

Fig. 2—Sketch of right side of six-cylinder Napier motor, showing the diaphragm connection from the carbureter to the water pump, secure wiring, and four points of fastening to the chassis frame.

(A) Thirty horsepower, shaft drive (R. A. C. rating 25.3 horsepower), which is known as No. 16, with a landau body, which includes a canopy over the driver with a means for carrying it on the runabout opposite the driver's seat on the right side.

(B) Forty horsepower, chain drive, with a special chassis, including a three-speed transmission, pressed steel frame, 11-foot 2-inch wheel base, standard gauge, three-quarter platform near rear, and a wheel equipment which includes 880 by 120 (millimeter measurement) tires on all wheels. The gearcase has ball bearings, and the anti-friction equipment extends throughout, with the exception of the crankshaft, which has plain bearings.

(C) The 45-horsepower motor (R. A. C. rating 38.4 horsepower), unlike the 40, is fitted into a chassis which rolls on wire wheels. The tire equipment on this chassis is 880 by 120 front, and 895 by 135 rear, in millimeters. This model is a shaft drive, has a three-speed transmission and pressed steel frame. The wheelbase is 11 feet 2 inches, with standard gauge.

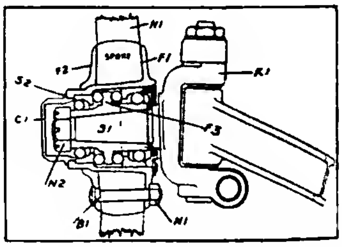

Fig. 3—Sketch of the front wheel and knuckle, sectioned to depict ball bearings for radial and thrust loading.

(D) The 60-horsepower motor (R. A. C. rating 60-horsepower) has a motor with a bore of 4 inches and a stroke of 5 inches, and six cylinders, of course. The wheelbase of this chassis is 11 feet 2 inches, with standard gauge. The tire equipment is 880 by 120 front, and 895 by 135 rear, in millimeters.

(E) The 90-horsepower motor (R. A. C. rating 89.9 horsepower) is a shaft-drive car, with wire-spoked wheels, and a wheelbase of 11 feet 11 inches, with standard tread. The tire equipment is 935 by 135, front and rear, in millimeters.

In addition to the models as above outlined, the six-cylinder Grand Prix is to be remembered, the R.A.C. rating of which is 59.2 horsepower. Then, there are commercial models of the Napier for every conceivable purpose.

It would be difficult to state just which of the Napier models are the most popular, or which have the greatest power. The best way, perhaps, for one who may be interested, will be for him to consult his own individual needs, with the understanding that there is a Napier model to be had to fill substantially every one. In order, however, to bring out the characteristics of the Napier school of design, reference may be had to Fig. 2, of a six-cylinder motor, in which the cylinders C1, C2, and C3 are cast in pairs, have a symmetrical exterior, six holding-down bolts, B1, B2, B3, etc., three of which are on each side of each pair of cylinders, and the flanging is so contrived that imperfections in the section of the casting at the junction of the flange with the wall are aborted, and in the same way, the thicknesses of walls and scheme of design assure perfection of the foundry work, ease and precision of the machining process, and other desirable properties.

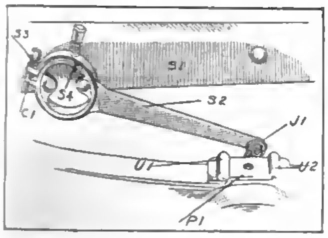

Fig. 5—Sketch of Napier shock absorber, method of applying, and means afforded for taking up lost motion using a spring.

The carbureter, C4, is on the right side of the motor, is especially designed for the desired flexibility of the motor, has means for converting the atomized fuel into gas form before it enters the cylinders, and carbon formations are thereby reduced to an unimportant minimum. The water pump, W1, is located in front of the carbureter, and is driven by a shaft which has two bearings in motor arms, and connects with the half-time gear system, which is in the housing H1.

The lower half of the crankcase, C5, is so shaped that the lubricating oil is held therein, and is circulated through the pipe, P1, by a pump, thence to the journals to be lubricated, and back, thus saving all but the small amount which is burned in the cylinders, with the added advantage, however, that it is properly filtered during each cycle of its travel.

Ignition involves the use of the Napier synchronized accumulator and high-tension magneto. This system is well known for its simplicity, and the excellence of the spark afforded, and require but the use of one coil, in conjunction with a low-tension make and break, with means for perfectly timing the spark. The magneto is especially provided with a synchronized gear-driven mechanism, which renders it fit, without detracting from stability, or adding complication. Referring again to Fig. 2, it will be observed that the wiring, W2, is suitably encased in a tube, T1, and that the wiring passes out of a box, B4.

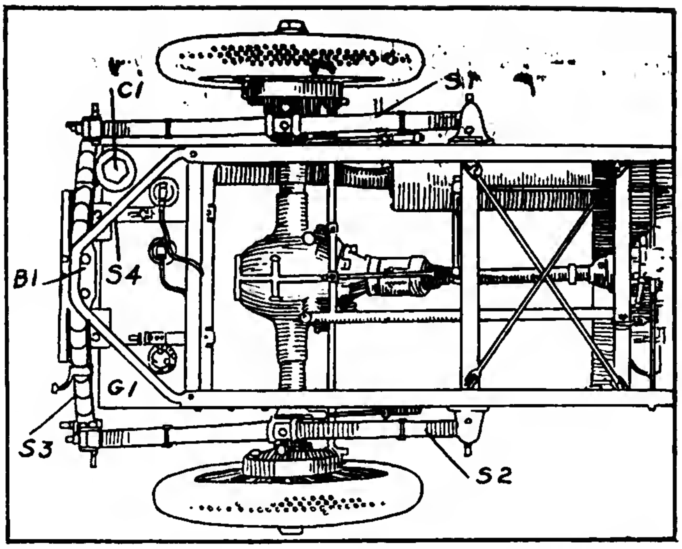

Fig. 4.—Sketch of rear of chassis, showing the long half-elliptic side members and cross member of the platform spring system, live rear axle, rear bracing, and gasoline tank.

Fig. 4 shows the rear of a Napier chassis, with long half elliptic springs, S1 and S2, a lateral spring, S3, at the rear, and a stout support, S4, which takes the work at a midpoint on the lateral spring. A secure bolting system, B1, maintains the position of the lateral spring, S3, and the gasoline tank, G1, is nested under the chassis frame in front of the lateral spring, S3, with a filler cap, C1, in a clear situation, as shown.

Fig. 3 shows the front wheel hub in section, with stout hickory spokes, H1, clamped between flanges F1 and F2, with bolts B1, so arranged that they may be pulled up tight by means of a nut, N1, without causing trouble by turning with the nut.. The knuckle, K1, is of the desired proportions, with a tapered spindle, S1, and the double system of ball bearings, the central members of which, being placed to take thrust loads, with a flange, F3, so placed as to interfere with axlewise motion. The hub nut, N2, presses the inner race up against the tapered spindle, and is locked by means of a cotter pin which registers with castellations in the nut. The hub cap, C1, screws up against a shoulder, S2, hence it will stay in place without other locking means.

Fig. 6—Napier taxicab and town car model with a wheelbase long enough to make the entrance commodious and chassis low to match

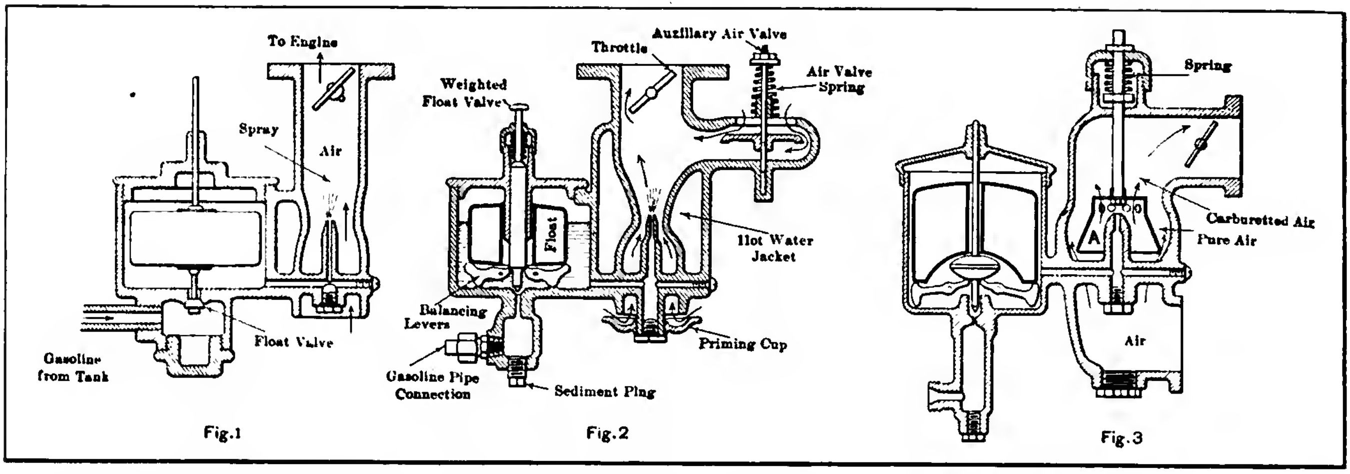

Fig. 1—Elementary non-automatic float-feed carbureter. Fig. 2—Automatic float-feed carbureter having Venturi mixing tube and spring controlled auxiliary air valve. Fig. 3—Automatic float-feed carbureter in which all air enters by one intake. The spring controlled valve A determines by its lift the amount of air which passes around it without taking up gasoline. At low speeds the bottom edge of this valve A almost touches the casing, so that practically all the air goes up past the spray nozzle.

THE CARBURETER, ITS ADJUSTMENT, AND THE NOVICE

By HERBERT L. TOWLE.

PERHAPS the best advice for the novice regarding his carbureter is to let it alone till he understands something of its working. It is very easy to spoil a good adjustment by random tinkering, and much less easy to restore it.

Nevertheless it is certain that, some time or other, every owner will be thankful to know as much as possible about his carbureter. At best the carbureter is a somewhat delicate device, and cannot be otherwise, from the fact that the forces acting on it are only those of the engine suction. Some time or other—it may be next month or next year—some trivial thing will go wrong. If the owner understands his carbureter he will trace and correct the trouble in a few minutes. If he does not, he will waste hours hunting for it, or pay the too-willing garage man to help him make a mountain of a mole-hill.

It is common prudence, therefore, for the reader to take the first opportunity to learn all about carbureters in general, and his own in particular. You should know what the spray nozzle, float and auxiliary air valve are; how they work and how to get at them; how to drain off sediment, clean the strainer and disconnect the gasoline pipe; what the several adjustments are, and what results may be expected if they are changed; what changes are likely to be required by variations in weather, altitude and fuel; and, finally, what the symptoms and the treatment are of the commoner derangements to float, gasoline supply and air valve. Although the information last named cannot come first it is quite as important as the preceding to your peace of mind and economy of purse.

In Fig. 1 is shown an elementary type of carbureter, now obsolete, but the basis of most modern types. It works on the principle of an atomizer, air being sucked past a nozzle from which a jet of gasoline is aspirated. The normal gasoline level is kept just below the nozzle by a float controlling a valve through which the gasoline must pass on its way from the tank. The tank is placed higher than the carbureter or else is under air pressure to lift the gasoline. This type of carbureter is unsatisfactory for two reasons:

1. When the engine is running slowly the velocity of the air past the spray nozzle is not sufficient to draw gasoline, or to break it into spray, if drawn. To increase the air velocity at slow speeds, the passage around the spray nozzle must be constricted, and that would reduce the capacity of the carbureter at high speeds.

2. When correctly adjusted for low speed, too much gasoline is delivered at high speed. This fact is due to liquids and gases obeying different laws of flow. To a certain extent this difficulty may be met by using special forms of nozzle orifice.

To overcome both objections at a stroke the automatic carbureter was devised, a common form of which is shown in Fig. 2. Here the air passage around the spray nozzle is constricted so much that a small flow of air will produce a spray. To admit sufficient air for high speeds, and at the same time to dilute the carbureted stream—which, as above noted, is too rich at high speeds—pure air is admitted through an auxiliary valve which opens only when the suction exceeds a certain amount. The lift of this valve and the quantity of air passing through it depend on the suction, the form of the spring, and the shape of the air passage around the valve. When properly proportioned this carbureter will deliver gasoline and air in nearly constant ratio at all degrees of suction within its range. To arrive at the correct proportions, however, is a difficult matter, and not all carbureters

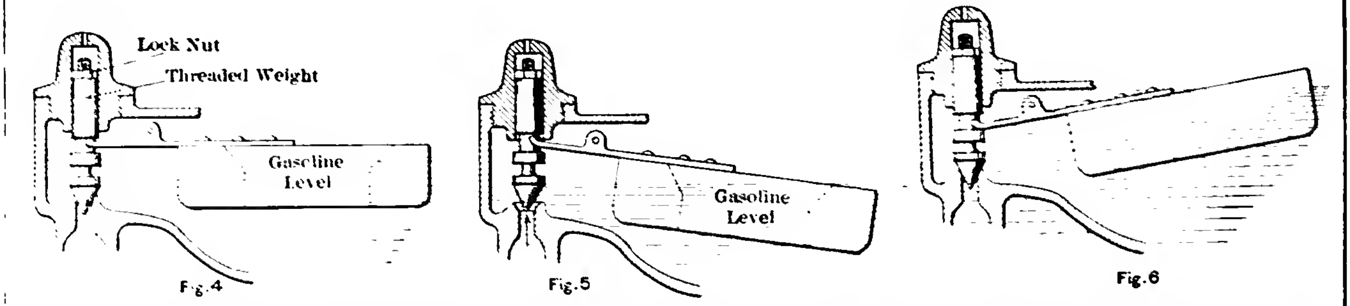

Fig. 4—Simple type of float and float-valves with gasoline level normal. Fig. 5—The same, with low gasoline level, showing how float-valve opens. Fig. 6—The same, with leaky float-valve. The float rises but cannot check the leak, and float chamber floods

are equally successful in that regard. The common adjustments are four in number:

1. The float valve, which regulates the gasoline level.

2. A needle valve controlling the size of the spray orifice (not shown in Fig. 2).

3. The tension of the spring controlling the auxiliary air valve.

4. A stop limiting the extreme opening of the latter.

Raising the gasoline level makes it easier to start the engine, but if carried too far causes gasoline to run continuously from the nozzle. Opening or closing the needle valve controlling the spray orifice gives more or less gasoline throughout the entire range of action. The auxiliary air valve spring is under some tension when the valve is closed, therefore a certain suction is required to open it. This compels all the air to go past the spray nozzle at low speeds. The exact form, length and tension of the auxiliary valve spring have a great influence on the opening of the valve at different degrees of suction. Slackening the spring obviously permits the valve to open more or at a lower suction, and vice versa. The function of the stop is to prevent the valve from opening too much under high suctions. The object of this is partly to prevent fluttering of the valve, but chiefly to prevent excessive air from being drawn in. If the spring controlling the valve is of equal diameter throughout its length, and but one spring is used, the valve will open too much at high speeds unless arrested by the stop. This fact is met in most recent carbureters by making the spring conical, so that its resistance to bending increases progressively, or by adding a second and stiffer spring which comes into action when the valve is partly open. Such a valve is much more nearly automatic than that with the simple helical form of spring.

Starting from the typical form in Fig. 2, modifications of detail have been indefinitely multiplied. Some carbureters have two or more separate nozzles and mixing tubes, one large, one small, of which the smallest starts first with the weakest suction, and the second and others (if any), are brought into action successively as the suction increases. In some carbureters, bronze balls seating over holes of different sizes take the place of the spring-controlled air valve and open one after another. In still others, all the air enters by a single primary opening, but divides, part of it going past the spray nozzle and taking up gasoline, while the remainder is shunted around the spray nozzle and dilutes the carbureted stream. The automatic valve acts on the pure air supply only, increasing it with the suction. An example of this form of carbureter is shown in Fig. 3. The auxiliary valve has somewhat the form of a bell, and is attached to a stem controlled by spring. As the suction increases the bell lifts and more air passes under its lower edge to join the carbureted stream coming through perforations in the upper part of the bell.

Whatever his carbureter, the novice can with a little trouble identify its various elements; and, aided by sectional illustrations, he can learn how to get at them for inspection. The internal parts most apt to need attention are the strainer (if any), located usually between the gasoline pipe and the carbureter, but sometimes built in underneath the float chamber; the float valve and float, and the spray nozzle. Of these the strainer needs occasional cleaning; the float valve is adjustable to vary the gasoline level; the float needs no attention unless it becomes soaked with gasoline, or punctured (if of metal); the spray nozzle takes care of itself unless choked by a particle of dirt, which must be poked out with a wire. Besides these are the sediment plug or pet-cock; the needle, if any, adjusting the spray nozzle, and the air valve spring and stop, all of which are external and visible.

We come now to the minor adjustments needed by any carbureter owing to changes of weather and the like. Few carbureters are as efficient on a very wet day as on a dry day, on account of the reduced capacity of the air to absorb further moisture. For this reason an excess of gasoline must be supplied by increasing slightly the needle valve opening of the spray nozzle, if there is one. Carbureters having no spray needle are provided with other means of regulation, usually by modifying the suction at which the auxiliary valve opens. To produce an effect similar to enlarging the auxiliary air valve spring tension is increased, thus admitting less air.

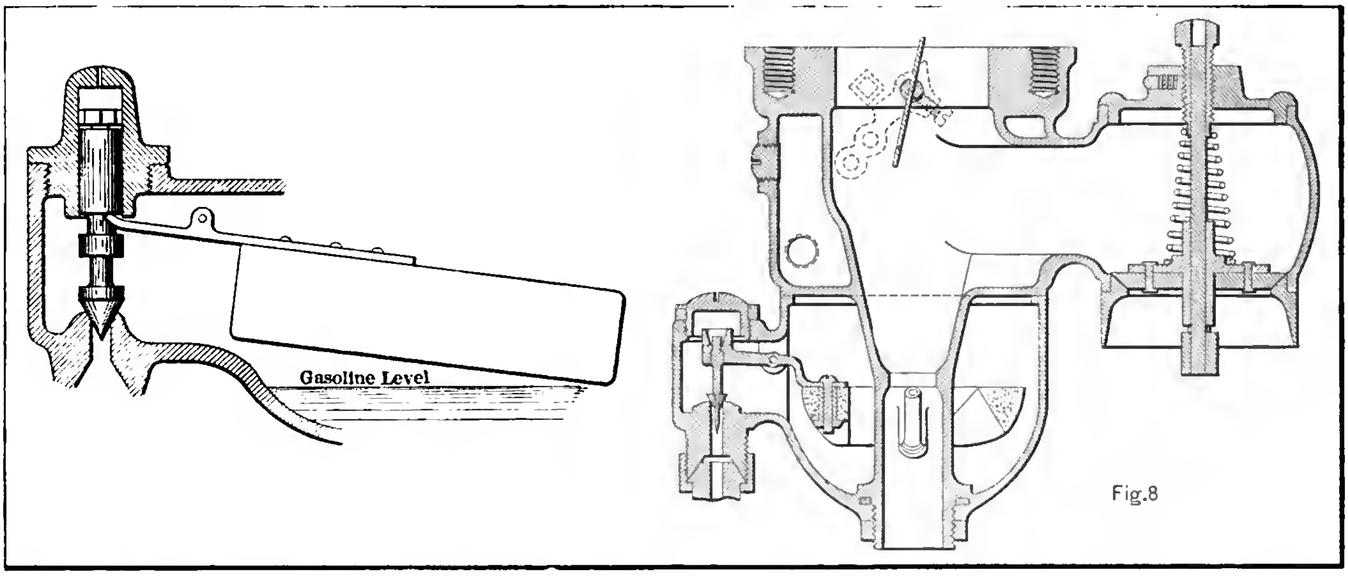

Fig. 7—The same. Threaded weight on float-valve stem is loose, and the stem settles downward by gravity and shuts off the gasoline despite depression of float. Fig. 8—Section which shows how the float relates to the other parts

A change in fuel density always demands readjustment, sometimes of every adjustable element, in order to get the best possible results. If the gasoline be heavier the float will ride higher and therefore maintain a lower gasoline level, thus demanding the adjustment of the float valve. As the heavier gasoline is more viscous the spray opening may need to be slightly enlarged. Additional heat is likely to be required. A marked change in altitude is another thing which sometimes upsets carbureter equilibrium.

Every owner has to change adjustments more or less from winter to summer, although the best carbureter is that requiring the least change. Gasoline, like any other liquid, absorbs heat on evaporating, and unless the air and surrounding piping are warm enough to supply the heat easily the air may be so chilled as to freeze the moisture contained in it. The ice thus formed will choke the mixing chamber. To prevent this, many carbureters are "hot water jacketed."

(To be continued.)

Test of Franklin Air-Cooled Motor*

By L. R. Evans, M.E. and R. P. Lay, M.E.

MATERIAL for this article was taken from a thesis, the work on which was done by the writers in 1907 at Sibley College, Cornell University.

The main object of the work was to study the variation in the volumetric efficicney of the motor caused by changing the timing, the shape and size of the valves and the material used for the cooling fins. Several additional items were observed during the tests so that we were able to compute other results. The complete engine and transmission were furnished by the manufacturers from their 1907 stock. They also sent two additional sets of cylinders having different cooling fins or valves. Each set of cylinders was put on the same crankcase and tested in the same way.

The following is a brief description of the engine and the method of making the tests:

The Engine—For clearness it may be advisable to give a description of the motor on which the tests were conducted. It is of the four-cylinder, four-cycle type, with a 4-inch bore and stroke and a rated capacity of 20 horsepower at a piston speed of 1,000 feet per minute. The cylinders are cooled by radial flanges, either cast integral or shrunk on to the cylinders, a fan being used to force air between them while the flywheel is designed to further increase the draft. The boot, hood and footboard are all designed so as to give air a direct passage from front to rear.

Three different sets of cylinders were used in the tests, each being of a different design. The first set was made of close-grained cast iron with the cooling fins cast integral with the cylinder shells. The second and third sets were cast-iron shells with very thin walls, carefully machined on the outside, on which phosphor-bronze flanges were shrunk to form the cooling fins. These disks were spaced equally on each separate cylinder, but the number of discs on the various cylinders varied with their positions relative to the fan. No. 1, the forward cylinder, had 12 fins, Nos. 2 and 4, 14, while No. 3 had 17. the purpose of this design being to keep all the cylinders at the same temperature, approximately. The first and second sets of cylinders had flat heads with two openings for valves which were separate, while the third set had spherical heads with one opening in which the valves were placed concentrically—that is, the exhaust valve was placed within the inlet valve, which formed its seat.

*Paper to have been read at the Winter meeting of the Society of Automobile Engineers, 1909.

Pistons and Wrist Pins—The pistons were cast of the best quality of close-grained gray iron and were finished on the outside by grinding, the inside being left rough. Each piston was provided with three eccentric piston rings, made of cast iron and ground to fit the cylinders. Hollow wrist pins made of cold rolled stock, hardened and then ground, were used in each case. They were held in place by cotter keys and were kept from rotating by means of small tool steel pins set crosswise in their ends so as to mesh with a slot cut in the pistons.

Connecting rods were made of nickel steel, drop forged with an elliptical section. The crank end was fitted with a split babbit bearing held together with four cap screws while the wrist pin end was bushed with a bronze bearing, pinned in place to prevent rotation.

Crankshaft was made of the best quality nickel steel, drop forged and finished by means of lathe and grinder to 1.5 inch at both the crank and the connecting rod bearings.

Crankcase and Main Bearing—The crankcase was cast of a special aluminum alloy, being finished inside and out by means of a boring mill and milling machine. The main bearings, five in number, were made of die cast babbit with aluminum alloy pedestals.

Flywheel, Clutch and Fan—The flywheel, which was made of iron cast with blades instead of spokes, also carried a clutch of the multiple disc type with alternate bronze and steel discs The six-bladed aluminum fan was gear-driven from the main shaft by two to one bevel gears, the fan being connected to its drive shaft by means of a friction clutch, so as to minimize the strains induced by sudden stoppage of the engine.

Valves and Mechanism—The valves were three in number. all mechanically operated; the inlet valve, the exhaust valve and the auxiliary exhaust valves respectively. The inlet and exhaust valves were placed in the heads of the cylinders, while the auxiliary exhaust valve was connected to a port so placed in the cylinder that when the piston had moved through seven-eighths of its stroke. the port starts to open. Through this port nearly all of the products of combustion escaped so that but little was left to pass through the true or main exhaust valve. It is to the auxiliary exhaust that the successful cooling of the motor is almost entirely due.

The first two sets of cylinders had separate valves for both inlet and exhaust in the head, but the last set tested were fitted with concentric valves. This form of valve gave a larger area of opening for the inlet valve and hence a greater charge of

Horsepower Becomes Constant After 18 Minutes' Running

mixture was introduced into the cylinders by each suction stroke, with a consequent increase in the power of the engine. In all cases the valves were actuatd by eccentric cams, through push rods and walking beams, so linked together that the motion of the valve was about twice the movement or throw of the cam.

Timing—The first set of cylinders was tested with the valves timed in two different ways. First, the valves were timed so that the inlet valve opened 7 degrees before center and closed 17 degrees past center, while the exhaust opened 13 degrees past center and closed on center. This has been called timing A. Next, the relative position of the two-to-one camshaft gears were changed by one tooth so that the inlet valve opened 5 degrees past center and closed 30 degrees past center, while the exhaust valve opened on center and closed 12 degrees past center. This has been called timing B. The auxiliary exhaust valves were always timed so as to open about the middle of the expansion stroke.

Carbureter—The carbureter was of the float-feed type with a multiple jet gasoline nozzle placed in the center of a Venturi tube. A butterfly throttle valve was used, connected to which was a second valve of the same type that controlled the opening of a by-pass through which air could be drawn around the nozzle. By means of the auxiliary air which did not pass the nozzle, the proportions of the explosive mixture were approximately maintained constant for all speeds of the engine. The float feed was so adjusted that the gasoline level was about 1-8 inch below the top of the spray nozzle at all times. The supply of gasoline to the spray nozzle was controlled by a needle valve which was operated from the dashboard. A flap valve was placed in the intake pipe of the carbureter in order to furnish sufficient suction when the engine was cranked to start. This valve drops down and closes the intake pipe and a greater suction is produced in the carbureter with the result that a much richer mixture is available for starting. After the engine is cranked, this valve opens and remains open.

Ignition—The ignition system consisted of a Pittsfield four-unit spark coil, mounted on the dash, a Pittsfield timer and a Witherbee storage cell. Pittsfield spark plugs with mica cores were used throughout the test. In the first set of cylinders the plugs were placed in the sides, but in the last two sets they were placed in the tops of the cylinders as nearly central as possible. The timer was so adjusted that the time of ignition could be regulated to suit any speed of the engine.

Lubrication—Splash and force-feed lubrication was used in this motor, the engine being provided with a sight and force-feed McCord oiler mounted on the dash and belted to the end of the camshaft. Two pipes were run to the center portions of the crankcase, while the remaining two were connected to the rear main bearing and the fan gearcase respectively. Throughout the test Floyde 600 degrees fire test lubricating oil was used in the oiler, while from time to time a small quantity of powdered graphite was placed in the crankcase.

Control—The engine was provided with a spark and throttle control, and the necessary levers were mounted on the dash and on the engine, being connected to the timer and throttle respectively. In addition to this, a governor, which was mounted on the camshaft .was connected to the throttle valve in such a manner that the engine was prevented from racing when the load was suddenly removed.

Transmission was of the progressive sliding-gear type, with three speeds forward and one reverse. On the high speed, the crankshaft of the engine was directly connected to the driveshaft of the transmission and it was this speed that was used throughout the test, the drum of the Prony brake being mounted on the end of the transmission driving shaft.

General arrangement of the apparatus was this: The air drawn into the engine through the carbureter was measured by a Wylie air meter, manufactured by the Equitable Meter Company, of Pittsburgh, Pa. A large air receiver was connected in the line to steady the flow of air. The gasoline was drawn from

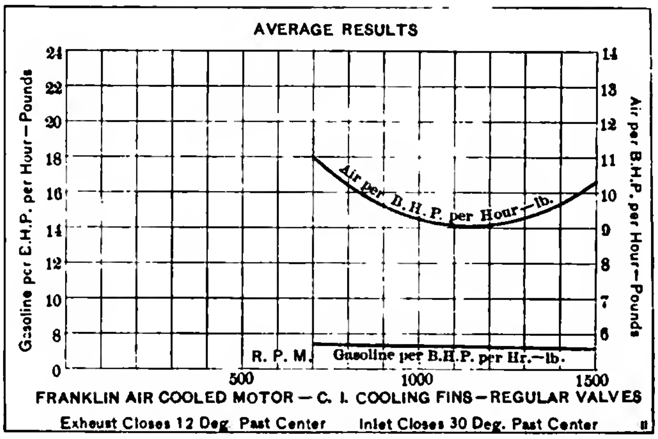
The Curves Are Not Parallel, Owing to Different Scales



Explaining the Need of Entirely Automatic Carbureters

a calibrated tank outside the building. The energy was absorbed by a Prony brake.

The air meter was calibrated by the manufacturer and also, under the conditions of the test, by an electrical measuring device contained in the 5-inch pipe connected between the meter and engine. The results of these two calibrations showed that the meter was correct within the range used during these runs. The lower heating value of the gasoline used was found by test to be 18,480 B.t.u. per pound.

Description of Test—The general object and method of procedure used in obtaining the data for the different runs is best shown by the following outline on which the tests were based:

Object: Study of volume and weights of air drawn into motor.

Method: By metering the carbureter air.

Plan: A. Cylinders with cast-iron cooling fins and separate valves were placed on engine and the effect of temperature and valve timing on the volume of fuel mixture drawn into engine was determined.

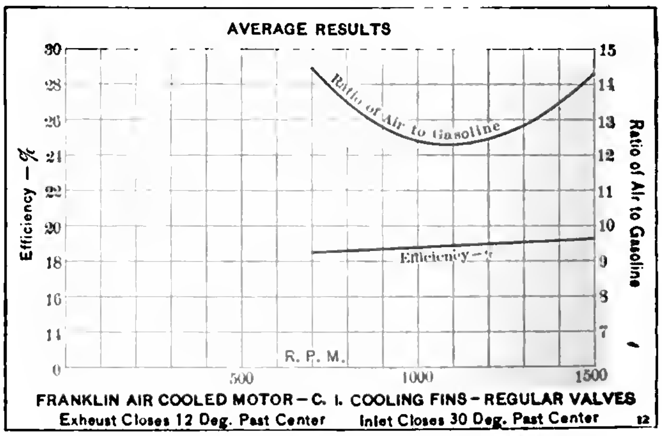
a. Accurate data was obtained with valves timed regularly timing B (exhaust closes 12 degrees past center and inlet closes 30 degrees past center), 30-minute tests being run at speeds of 700, 1,000, 1,200 and 1,500 r.p.m., with readings taken every two minutes.

b. Camshaft gears were shifted one tooth so that exhaust closed on center and inlet closed about 17 degrees past center, timing A. Tests were made at speeds of 700, 1,000, 1,200 and 1,-500 r.p.m.

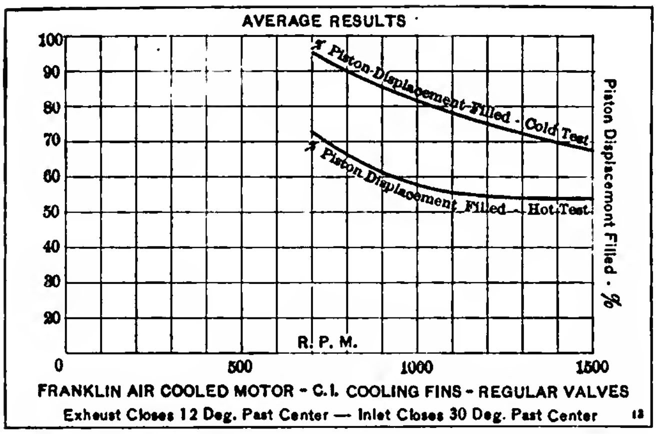
B. Cylinders with phosphor-bronze cooling fins and separate valves were placed on engine, and the effect of temperature and valve timing on the volume of fuel mixture drawn into engine was determined.

a. Tests according to (A-a) above were run off.

C. Cylinders with phosphor-bronze cooling fins and concentric valves were placed on engine and the effect of temperature



Proportions of Mixture Vary with Constant Efficiency



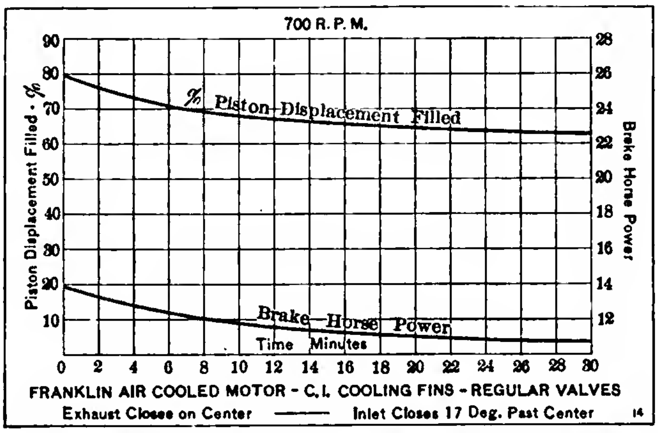
Showing the Effects of Running Both When Hot and Cold

on the volume of fuel mixture drawn into engine was determined.

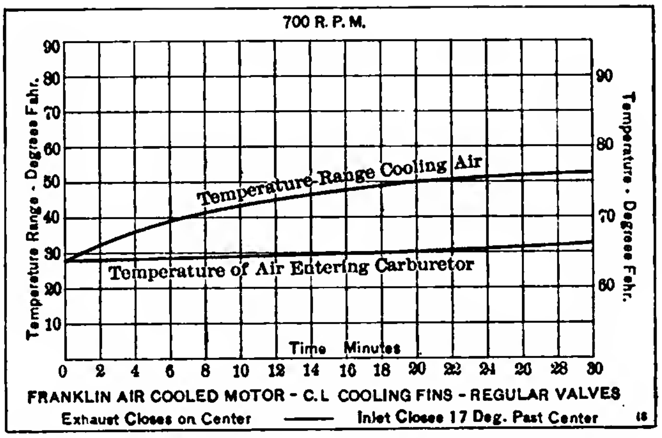
a. Tests according to (A-a) above were run off.

All of the tests, which were of one-half hour duration, were made as follows: Starting with the engine cold and the throttle wide open, the spark, carbureter needle-valve and the brake were adjusted so as to give maximum power at a given constant speed, at which the run was to be made. Then the gasoline tank gauge and air meter were read and the continuous counter, having been set at zero, was engaged with the brake drum shaft. During the run the following readings were taken every two minutes: Air meter, continuous counter, brake scales, temperature of air entering carbureter, temperature of air entering hood of engine, temperature of air leaving hood of engine, pressure in air receiver, pressure in suction header and temperature of gasoline. At the end of the run the air meter and the gasoline tank gauge were read, the continuous counter was disengaged from the shaft and the specific gravity of the gasoline was determined.

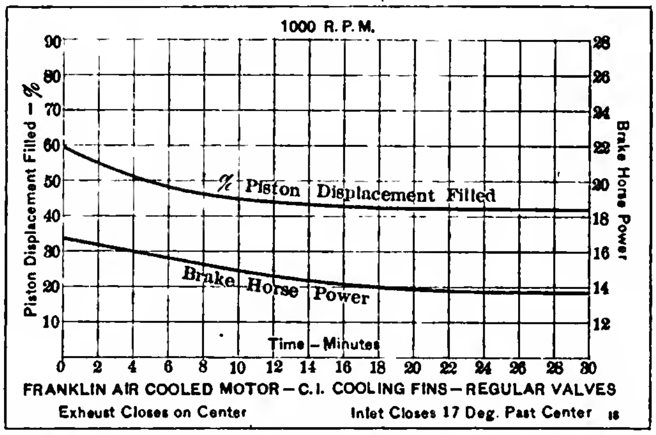
The results appearing in this article were computed from a large mass of data selected as follows: The engine was first put into such condition that it would pull the proper maximum horsepower at 1,500 r.p.m., then a complete set of tests, as. for instance (A-a), were made, starting with 1,500 r.p.m. At the end of each run the engine was carefully inspected for leaky valves, faulty ignition, etc., and the valves timed hot immediately after the engine was stopped. After satisfactory data was obtained for the four runs of the set, check runs were made precisely similar to the first. Then from the checked data, that data which was most consistent was selected for computation. Whenever, as frequently happened, the second set of runs did not check the first, then more runs were made until two runs were obtained that did check. Sometimes it was found necessary to make as high as seven runs before satisfactory data was obtained. It was hoped that in this manner all sources of error would be eliminated. As a further precaution, the engine was torn down and completely rebuilt after the data for each series



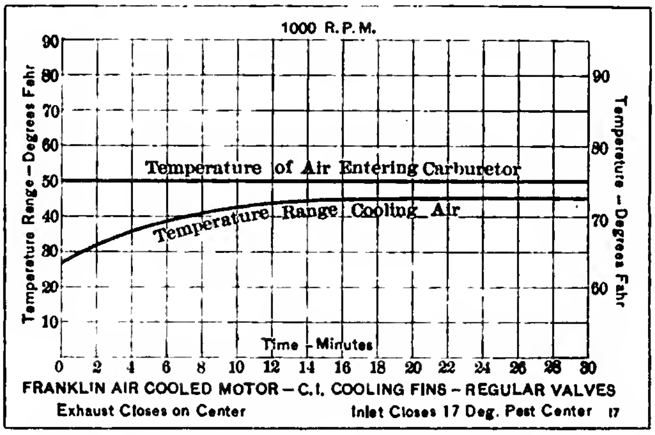
Horsepower Much Impaired by the Change in Valve Timing



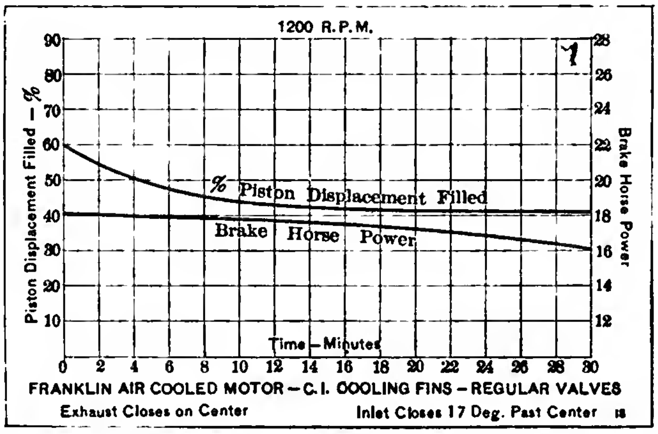
Greater Relative Increase in Temperature of Air Used



Horsepower Still Further Reduced at Higher Motor Speed



Cooling Air Slower in Reaching Its Maximum Temperature



Shape of Horsepower Curve Much Changed by Valve Timing

of tests had been satisfactorily obtained. The data is not given because it would take up too much space, but in the following table are given the most important average results:

From the results of the first set of tests it was evident that timing B gave so much better results than timing A that the rest of the tests were run with only the one timing B. For each set of runs will be found curves showing the variation during the runs of the temperatures and the volumetric efficiency and other sets showing the ratio of air to gasoline, etc.

The volumetric efficiency is less than 100 per cent., because the valve opening is not large enough and the charge is throttled in entering the cylinder; also because the cylinder is hotter than the entering gas and causes it to expand. In order to separate these two losses, the engine was belted to an electric motor and run at same speeds as during the tests. The spark was shut off, but everything else the same, even leaving the gasoline turned on. The valves were timed with the motor cold. Readings were taken for a half-hour run and from them the cold volumetric efficiency computed.

Sets of curves for each set of runs were plotted showing the volumetric efficiency with the engine hot and cold. The ordinate between the curve for the cold test and the 100 per cent. line is, of course, the loss due to the small valve opening, the ordinate between the two curves being the loss due to the hot cylinder. The effect on the efficiency of changing the timing can be seen by comparing the first two curves.

How Efficient Lubrication Reduces Maintenance

ASIDE from the qualities of oils which have been previously mentioned, there are a number of qualities which are worth mentioning, in fact are spoken of daily. These are the matters of color, fluidity, flash point, fire test and cold test, all of which are of some vital importance. To define and expand upon these will be well worth the space taken up.

Color is a very misleading quantity, because it has very little influence upon the actual worth of the lubricant as a preventer or reducer of friction. When the word light is used in connection with oils, what is meant is the specific gravity and not the color. Color or lack or it is either inherent in the oil, and a result of the process by which it is made, or it is produced by artificial means. Bleaching with acids may result in clearing the color of the oil, but it may also leave traces of acid in the oil, so that the slight benefit to be gained (if any) from this process is attended with much danger. Filtration will achieve the same result with no corresponding drawbacks, so that an automobilist who for some reason desires a light colored or clear oil should insist on one which is either made that way, or in which the result is achieved by filtration.

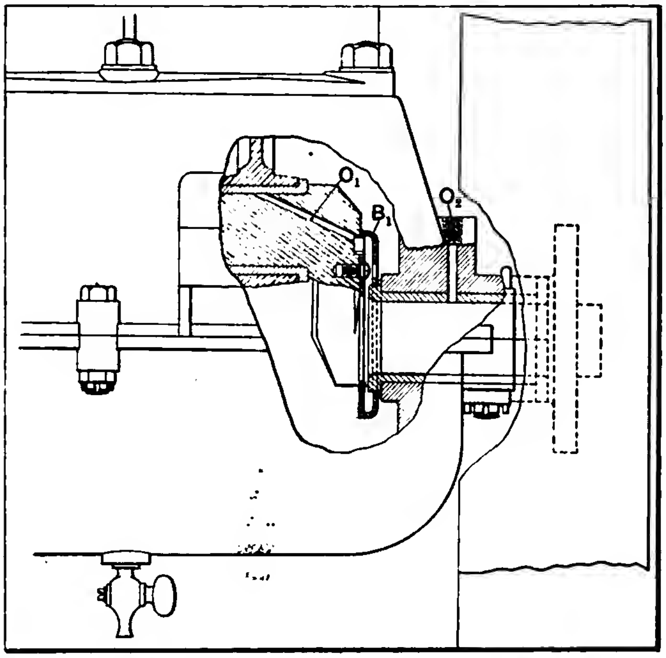
Specific gravity is usually measured in degrees Baumé, at a known or fixed temperature. The latter is a necessity, since the lubricant would have a variable weight per unit amount, as compared with a standard, in varying weather, such as summer and winter. In other words, cold weather would expand the lubricant just as it does other fluids (barring water), so that the unit weight would be less in colder weather. Figures showing the general average are not available, but as a few instances the following are cited. The Pennsylvania Railroad specifies that one grade of oil (paraffine and neutral oils) must have a specific gravity of 60 deg. Fahr. below 24 deg. and above 35 deg. Baumé. Another grade of lubricant (well oil) must have a specific gravity between 28 and 31 deg. Baumé, at 60 deg. Fahr.

Fluidity is that quality of oils and other lubricants which has previously been discussed under the head of body, that being the more usual term for it. By this, reference is had to the thinness of the lubricant, which produces easy flowing qualities, or the lack of which gives the opposite result, sometimes desirable.

Flash point is a temperature measurement, and is that temperature at which the vapor arising from the surface of the oil will take fire, or flash. That is to say, it is the *lowest* temperature at which the oil vapors will flash. Naturally this is a decidedly variable quantity, the flash point varying with the service for which the oil is intended. Thus, oils for cylinder use should have a very high flash point, while oil for transmission and rear axle bearings may have any old flash point. This quality of oils is closely allied with burning point, or fire test as it is usually called, so that in specifying one the other is usually specified also. Thus, for what is called 150 fire test oil, the Pennsylvania Railroad specifies that the flash point must be above 130 deg. Fahr. and the oil must not burn until the temperature passes 151 deg. Fahr. Another oil known as 300 test must not flash below 249 deg. nor burn below 298 deg. Fahr.

In automobile work, the fire test (and with it the flash point) will bear close watching, for cyinder use in particular. Thus, if an oil has a low fire test, when exposed to the very high temperatures of combustion, it will burn, and thus leave a residue, the presence of which is highly undesirable. This residue is what is known as carbon deposit, and it is very difficult to avoid, but much more difficult to remove. In the ordinary cylinder, the temperatures may run as high as 2,000 deg. Fahr., but such extremely high figures are only momentary, tapering down at one end to an exhaust temperature of perhaps 300 deg. Fahr., and at the other a varying temperature, which may be as low as the external air, or as high as the temperature of compression, just before explosion. The latter figure might he in the neighborhood of 125 deg. Fahr.

This gives a range of temperature of from, say, 60 to 125 deg. for the suction and compression strokes, jumping to 2,000 at explosion, falling off from that figure to 300 at exhaust, and then repeating. The lower temperatures prevail for two strokes, or one-half of the whole cycle, while the highest temperature prevails for but an instant, so that the average temperature which would be effective for this part of the cycle might be taken as close to an average of the initial and final temperatures, or in the case cited above, 2,000 and 300, or, say, 1,100 deg. Fahr. Doubtless



Ring Oiling Scheme for Lubricating the Crankshaft Bearings

a much lower figure would be more fair, for the pressure and with it the temperature falls off very rapidly, not only at the start but throughout half of the stroke, slowing down to a very gradual drop only at the end of the curve, just before the exhaust opening point is reached. For these and other thermodynamical considerations it would be well to consider the average value of the cylinder temperature during the power stroke as closer to 850 deg. Fahr. than to the figure previously given.

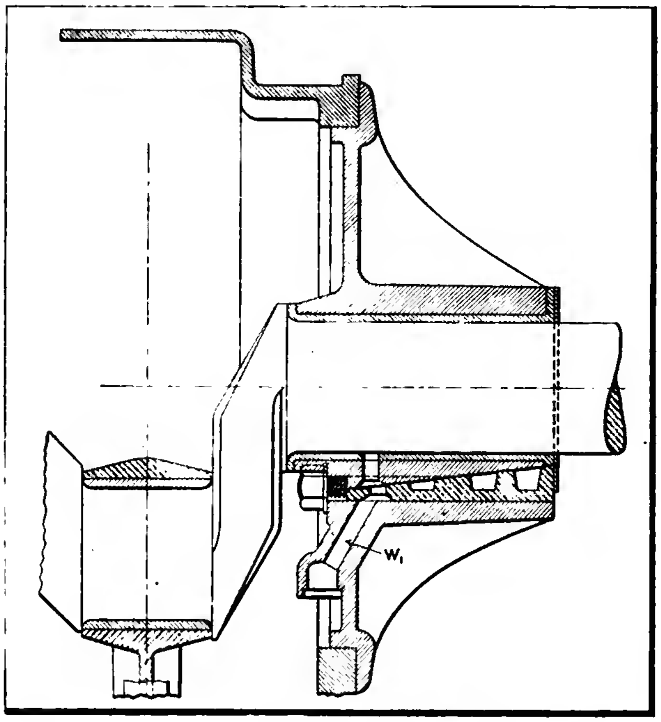
Following this line of reasoning, if the suction stroke be considered as varying from a remanent temperature of, say, 100 down to a final temperature of the mixture of 60, the average is 80 deg. The compression varies similarly from 60 up to 125, an average of say 90 deg., while the exhaust varies from, say, 300 down to 200, an average value of 250. If these four average temperatures be averaged over the whole four strokes, a figure of 315 deg. Fahr. is gained for the whole average cycle temperature. This, then, would be a good minimum value to assign to cylinder oils, bearing in mind at the same time the fact that this is momentarily exceeded by perhaps as much as 1,800 deg. Without a doubt, the above line of reasoning leads to the conclusion that cylinder oils should not have a lower fire test than 400 deg. Fahr., while a higher figure is, to say the least, on the side of safety.

Cold test is a quality not spoken of as much as the others, that is to say, it is generally neglected; this, too, without cause, for it is important. Cold test consists of testing the oil to see at what minimum temperature the oil will congeal. This is tested by gradually lowering the temperature of the oil, and noting the first point at which it ceases to flow readily. For winter use, however, the determination of the quantity is of much greater importance, and so is determined by another method. For this purpose the method employed is as follows: The oil is frozen, and then the temperature is gradually raised until a point is reached at which the frozen oil will just flow. This then is taken as the cold test point. Motorists in selecting an oil for winter use, other than for those parts like the cylinder, which keep the oil warm at all times when in use, should be selected according to the part of the country in which the car is to be used. Thus, for the average Northern United States location, a cold test of 10 deg. Fahr. would be sufficient, while Canada would require a lower figure of, say, 5 deg. down to zero.

On the other hand, the Southern States would not need such a low point, and since this quality influences the fluidity, otherwise called body, to a large extent, it is desirable to keep the cold test as high as possible so that the body qualities may be of the greatest possible use to the motorist. This then leads one back to the starting point, that is, to the statement that the cold test is generally neglected, and indicates a reason why it is neglected, namely, to gain all of the benefits of fluidity. However there is no reason why it should be entirely neglected, for it is possible to select the oil with care, and gain the maximum advantage with the minimum disadvantage.

To sum up, then, the points to be examined are: Identification of the lubricant as an animal or mineral oil, or a compound, as a solid lubricant or a compound of solid with fluid; density or specific gravity; viscosity; flash point; burning point; acidity; coefficient of friction, and cold test. These eight qualities are given in very nearly the proper order of importance, although nothing is said about cost, which in the usual case ought to be listed just as all other qualities. That is, instead of making it the main or deciding factor, it should have no more weight than any one of the eight other qualities, or, if desired, it may be inserted in the list above, giving it a place according to its worth.

When a man makes price the deciding factor in buying oils he makes a big mistake, for that should be second to quality. If economy were the real item, it would be better to go without oil. In considering price it should be valued according to two things; first, the actual cost of the oil itself, and second, the actual cost of the repairs or replacements which its use will entail, or did entail, in some period of time. Upon this basis, the best oil will be selected regardless of price every time. More than this, another slant is given the oil-buying question by this idea. If the oil be cheap, too cheap, so that the quality is poor, the amount of power lost in friction will be very high. This power loss will not be noticeable in repair bills, but it will appear, nevertheless, in upkeep bills, gasoline, oil, waste, etc. It can be checked up rather carefully by observing the mileage per gallon of fuel, using several different kinds of lubricant. Finally, every driver who is vitally interested in the subject of proper lubrication should keep tabs on all kinds of oil used and the results.



Another Bearing Lubrication Method as Used on Rambler Cars

FRENCH BUILDERS FAVOR SMALL FOUR-CYLINDER MOTOR

By W. F. BRADLEY

PARIS, March 21—After developing the one-lunger to a wonderful degree of efficiency, French small car builders are now showing a decided preference for four-cylinder motors of very small volume and low, or moderate power. An example of this is to be found in the conversion of the firm of Sizaire-Naudin, to the multiple cylinder idea, after several years devoted exclusively to the development of the one-lunger. The new production will be examined with particular interest from the fact that the firm has met with phenomenal success in the single-cylinder class, and has produced single-cylinder racers with a ratio of stroke to bore, which a few years ago would have been declared impossible. With a bore limited to 3 9-10 inches, the firm has shown how to make a nominal 8 horsepower develop 26 horsepower and break all speed records for its class. Part of the result is due to a stroke of 10 inches, relatively large valve diameters, light reciprocating parts, efficient lubrication, and the use of the most appropriate of metals.

The new four is the outcome of racing and touring experience with monocylindrique motors. Nominally, it is of the same power as the firm's single-cylinder model and can be fitted under the same bonnet without any structural changes. The four cylinders have a bore and stroke of 70 by 120 millimeters (2 7/10 by 4 7/10 inches) and though rated at 12 horsepower, has developed as high as 26 horsepower, on a 10 hours' bench test. The bore is long in relation to the stroke, but is short in comparison with a second motor already designed and tested on the road, and intended for next season's market, in which, for the same bore, the stroke is carried up to 170 millimeters, or 6 7/10 inches. This is the greatest ratio of stroke to bore that has ever been attempted on a car designed for the ordinary user.

CYLINDERS CAST EN BLOC A FEATURE

Block casting of the cylinders, thermo-syphon water circulation, high-tension ignition with fixed sparking point, are all modern features which have been adopted on the new Sizaire-Naudin. A distinctive feature is that the crankcase is divided into two parts vertically, and not horizontally, the two halves being bolted together, and each one carrying a ball bearing for the crankshaft, as in single-cylinder design. Naturally there is no central bearing, but this cannot be considered a novelty, in view of the fact that most constructors of small motors have decided that two bearings only are preferable. The use of ball bearings for the crankshaft, however, is new, Sizaire-Naudin being the only French maker of small motors to use other than plain bearings for the crankshaft. They have been led to this move by their experience with the high-powered 100-millimeter single-cylinder racing motors, all of which had ball bearings throughout.

INTEGRAL CAMSHAFT ON BALL BEARINGS

The camshaft, too, is mounted on ball bearings, and is machined out of the solid with integral cams. Although all eight valves are mechanically operated, there are only four cams for the entire set. The valves are superimposed, the inlets being inverted over the exhausts, and all having a diameter of 50 millimeters, compared with 70 millimeters for the cylinder. This is a much larger valve diameter than would be possible with the valves side by side on such a closely set motor. The exhausts are operated from below by tappets, according to standard practice, the only distinctive feature being a considerable lead to the exhaust opening.

Parallel with the camshaft, but on a slightly lower plane, is a fixed shaft on which are mounted four small rockers, one end of which comes in contact with the face of the cam, while the opposite end touches the intake valve tappets. The rocker arm is made to follow the profile of the cam by reason of a spring on its under face, just below the tappet. A spike-like projection on the tappet centers the spring, the lower seating of which is on the upper face of the crankcase. Holes are bored in suitable positions on the face of the crankchamber to receive these projections when this end of the rocker arm is depressed. Considered in a vertical plane, the camshaft has above it the exhaust valve tappet, and below it the small rocker arm operating the inlet valve tappet and the inlet valve by means of a vertical push rod, and an overhead rocker arm.

The overhead mechanism is the one that has been applied to single-cylinder models since the beginning, and has only been modified in detail for the new work it has to perform. On the cylinder head is bolted a steel housing which also serves as intake manifold. It is in two parts, each one receiving two valves, and is held down by five bolts. A lip is formed on the outer face of the housing, under which is slipped the lower bar of a steel link, the upper bar of which receives the rocker arm. At each end of the rocker arm is a socket, into one of which the extremity of the intake valve is received. while the other receives the ball end of the vertical push rod. The extremity of the push rod is threaded onto the main portion and locked with a couple of nuts, thus allowing for adjustment of the tappets. The exhaust valve springs being hidden by a movable steel plate, the only visible parts in movement are the vertical push rods and rocker arms.

IGNITION BY HIGH-TENSION BOSCH MAGNETO

A high-tension Bosch magneto is relied on for ignition. On the model described, it is in a very low and inaccessible position, driven by external gears. It has been decided, however, to raise it to the level of the frame members for more convenient examination. The instrument is a new model just produced by the Bosch company and remarkable for its small size. It is considerably smaller than the one employed on the single-cylinder models and is provided with glass inspection plates for verifying the contacts, without dismounting. The leads pass through a straight metal tube level with the base of the cylinders until they come opposite their respective plugs, from which point the insulated cable is passed up to the sparking plug. The only visible wiring therefore consists of four vertical lengths. At present a Zenith carbureter is employed, but will be changed later for one of the firm's own design.

Unusually large diameter inlet and outlet pipes are used for the water circulation. The supply of cooling water is contained in a plain vertical tube radiator, at the back of which is a large brass tank supplying a good head of water for the cylinders. The tank is only secured at the forward end, where it enters into the head of the radiator, to which it is riveted and brazed. A ventilator fan is not employed on the French models, but will be fitted where the car is intended for service in hot climates. Provision has been made for mounting it.

Splash is relied on entirely for lubricating the motor, the oil being carried from a dashboard lubricator to the rear bearing of the crankshaft, from which point it falls into the crankchamber. Both gasoline and oil tanks are carried on the dashboard, the former being in front and the latter just behind it. The arrangement reduces piping to a minimum.

Chassis features of the four-cylinder model are identical with those of the single. Suspension in front is by means of a transverse inverted semi-elliptic spring, mounted above a special type of front axle. A single plate clutch is employed, and the drive is taken direct from this point to the rear axle without passing through a gearbox. There are three forward speeds and reverse, all but the reverse giving direct drive through spur, instead of bevel gears. Rear suspension is of the three-quarter elliptic type. Fitted with a two-seated body a speed of over 50 miles an hour is guaranteed with this small car.

LATEST WEARING APPAREL FOR WOMEN AUTOMOBILISTS

THE illustrations offered in this article will afford an excellent idea of some of the leading styles of millinery and motoring coats, which are available for the season just entered. They represent a greater measure of stability, without detracting from smartness, than has ruled heretofore, and the earlier criticism, which had for its basis the fact that service was secondary to ultra fashion, does not now hold. The motoring costumes for this year will more nearly accord with the basis for true art, because excellence of appearance will not be at the expense of utility.

SMART MOTOR COAT AND BLERIOT TURBAN FROM RENARD

The influence of Rostand's play, "Chantecler," has so pervaded spring styles that even fabrics derive their names from features of the barnyard drama. "Rooster track," is the name given to this peculiar check pattern as depicted in Fig. 2, and it is used for some of the smartest of the new motor coats. This garment has particularly graceful lines, fitting the figure more closely than motor wraps of preceding seasons, yet having roomy armholes which make the coat most comfortable. There is a touch of bright color—also a direct result of the Chantecler influence—in the leather tabs which decorate the coat. These red tabs, with their brass eyelets are placed on lapels and cuffs; and form an odd belt arrangement at front and back of the coat. This notion of belting the garment at the front, leaving the sides in long lines, is a novel one and gives a trim look to a portion of the coat which often hangs ungracefully.

The turban is an eminently comfortable model for use under a motor veil. The drapery of very soft horsehair straw may be drawn down entirely over the hair at the back, and the turban is smartly trimmed with a metal ornament and a "bleriot" or shaving brush standing stiffly erect.

Fig. 1—Comfortable coat for wet weather wear

A PRACTICAL COAT

Secure against the most persistent onslaughts of rain and wind will be the maid enveloped in one of these cosy mackintoshes as presented in Fig. 1, which are big enough to fit easily over another coat beneath, and so cleverly cut that the effect is graceful and pleasing, and not in the least bulky. The gathered hood which may be turned up over hair and hat is an especially satisfactory feature, and when the hood is dropped on the shoulders a very trim, buttoned-up collar is revealed at the top of the coat, which fastens, as wet weather garments should, snugly up to the neck.

This garment, which comes from the New York Mackintosh Co., is of blue rainproof material with trimmings in the shape of black satin bands on the cuffs and covered black satin buttons. The seamless shoulder, and sleeve cut in one with the body of the coat give great freedom to the arms and make it possible to slip the mackintosh over even a wool wrap without discomfort. The pleats set in at the side under a simulated pocket flap, add jauntiness and grace to the coat, and the full hood in Red Ridinghood style has a youthful suggestion that is rather attractive.

NOTES ON FEMININE MOTORING APPAREL

Paris, March 14—There is no article of clothing in greater demand or of more service and comfort to the feminine contingent of automobilists than the knitted sweater, which may be worn under the loose coats when extra warmth is required. Many variations of the loose coat sweater are to be had. There are the full-length garment and many of shorter lengths, but the one best liked is that of the knee length. There are those of the single-breasted order, with the neck cut in a deep V; the double-breasted with a high, close collar, and those which fasten on the left side. White still heads the list, but there are many pretty models in dark blues, greens, grays, browns and new reds.

When it comes to headgear the motorist can satisfy her liking for hat, bonnet or hood. There are small hats of toque and mushroom shape, while the turbans offer no resistance to the wind, and these shapes lend themselves admirably to the draping possibilities of the veil. The motor car is wholly responsible for the revival of the picturesque hood. There are practical fur and cloth hoods for cold weather, which have as trimming little animal heads or big choux of soft ribbon, and which tie under the chin with ribbon strings.

Among late novelties are leather neckties of the four-in-hand style and a motor ring to fit over the gloved finger.

Fig. 2—New long coat of rooster track fabric

Worthy Ideas from France and Germany

Features of the La Buire (French) Chassis

Characteristic, and at the same time thoroughly workmanlike, is the design of the La Buire cars, made by the company of the same name at Lyons, France. A notable feature is the use in the change-gear and axles of a new type of double-row ball bearing, the balls in each row alternating, so that the bearing is no thicker than a single-row bearing of the same diameter.

La Buire motors are made in four sizes: three four-cylinders, 75 by 120, 85 by 140, and 105 by 150 mm., rated at 10, 15 and 24 horsepower, respectively, and one six-cylinder, 85 by 140, rated at 18 horsepower. The four-cylinder 15-horsepower motor, which is typical of the rest, has a block cylinder casting with all valves on the left side. The exhaust manifold is separate and bolted on; it has three openings connecting with the exhaust ports, and between these is provided with deep cooling flanges. The inlet ports are led between the front and rear pairs of cylinders, connecting with a Y-shaped manifold on the right side. Two plates cover the valve stems and springs. The camshaft is driven by a Renold silent chain.

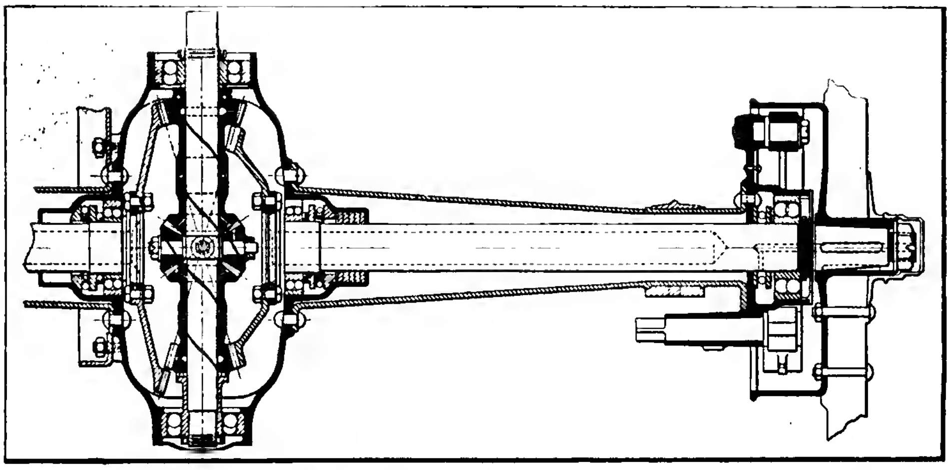
The water pump (centrifugal) and the magneto are mounted on the ends of a transverse shaft driven by skew gears on the front end of the camshaft. The water connections are made by union joints. This arrangement of the magneto brings it on the right side, with its circuit-breaker and distributor easily accessible.

Change-gear and clutch are united in the same case. the former being a four-speed selective two-throw type, and the latter a multiple-disc. The sliding-gear shaft is exceptionally long, forming at its front end a spindle which serves to line up the clutch shafts. The shaft itself has milled splines and for the sake of stiffness is made of large diameter and drilled out hollow. The constant-mesh gears have helical teeth, to secure silent operation, and since the end thrust otherwise would be considerable, are made double and reversed, forming what is known as herringbone gears. The gear case fills the whole space between the frame members, taking the place of part of the dust pan.

The rear axle is live and arched, the method of driving the inclined shafts being one which no American constructor has ever tried, although it is quite well known abroad. Each live shaft has a bevel gear on its inner end, these being of different diameters, although with the same gear ratio between themselves and their pinions. The pinion shaft extends clear through the case between them. having the pinion driving the left wheel on its front end and that driving the right wheel on its rear end. The differential is in the middle, between the two pinions.

The rear wheels are keyed directly on to the live shafts, and to secure the necessary additional strength at their outer ends these latter are made of large diameter and then drilled out from the inside ends—a repetition of the commendable, though expensive, process observed in the change-gear. The axle proper is built up of two dish-shaped pieces enclosing the bevels, and two tubular members. The latter have flanges turned at each end, and are riveted on one side to the bevel gear casing and on the other to the flange supporting the brake shoes, which also carries the outer bearings. Ball-thrust bearings are used extensively, there being no less than six of them in the axle, in addition to the six double-row ball bearings.

Drive to the rear axle is through a doubly-jointed shaft, not enclosed; a pressed-steel torsion lever is provided. The rear springs are three-quarter elliptics, or, optionally, full elliptics of the scroll type. The front springs are the usual semi-elliptics.



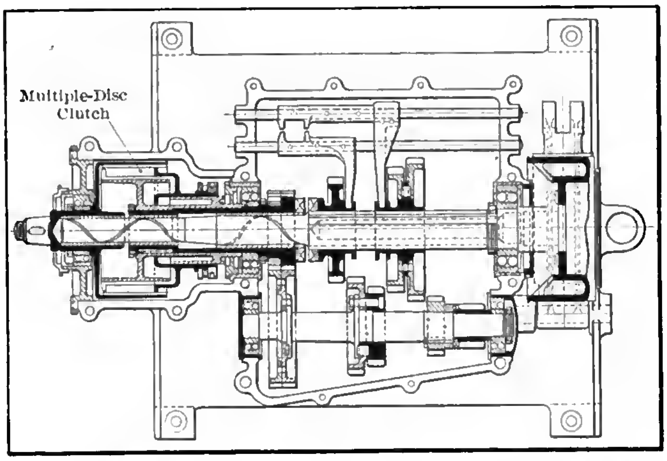
La Buire Uses an Arched Rear Axle with Drive through Two Pairs of Bevels

The Jaugey Carbureter, a Floatless Design

With the object of providing a carbureter which will work in any position and under any conditions, M. P. Jaugey, a French engineer, has invented a new floatless design, which is the subject of a description in *La France Automobile*, March 5. A photograph of one of the carbureters mounted on the inventor's car, a Clément-Bayard, was given in The Automobile of March 10, page 515. It is now possible to show a sectional drawing of the device.

The pipe from the gasoline tank opens directly into a closed cylinder pierced with three small holes, which are opened or closed by a piston sliding in the cylinder. This cylinder lies across the body of the carbureter, directly in the path of the air passing from the air inlet to the motor; the cylinder is surrounded by a concentric cylindrical shell which acts as the throttle valve. There are three air inlets; one always open, but with a shutter which can be adjusted to provide for different weather conditions; a second mechanically operated, and a third automatic, spring-controlled. The piston which varies the gasoline feed, the throttle valve and the mechanical air inlet are all coupled together and move in unison.

Most novel is the mechanically operated air valve. It consists of eight rods of different lengths arranged around and parallel to a central stem and registering with holes in the wall of the carbureter, in such a manner that the available air opening through the various holes is increased or decreased by sliding the device out or in. The central stem projects into the carbureter and acts as a stop to limit the opening of the auxiliary valve.



Four-Speed Gear and Multiple-Disc Clutch of La Buire

When the throttle is closed to stop the engine, the piston controlling the gasoline feed comes to a firm seat, and the throttle itself closes up all opening into the cylinder, so that there can be no leakage of gasoline. At low-speed running the throttle is opened slightly, thereby uncovering the first of the three gasoline outlets and providing a sufficient opening in the mechanical air inlet. Any variation in the speed of the motor with a constant throttle position brings the auxiliary air valve into action. At higher speeds the throttle is opened progressively, uncovering the second and finally the third of the gasoline outlets, with a corresponding area of air inlet.

This carbureter can be attached to the car in any position without impairing its functionment. On his demonstrating car M. Jaugey had it fastened to the side of the driver's seat, in the position usually occupied by the horn, and connected with the motor by some five feet of flexible tubing. It does not need to be heated, and will work under a film of ice, provided it has a free air inlet.

Drive Through Belt and Variable Pulleys

The Fouillaron system of belt drive is quite well known in Europe, having been in use there for a number of years with good success. So far as is known, though, the only time it has appeared in this country was at the St. Louis World's Fair, at which Fouillaron had an exhibit.

The motor shaft and the drive shaft run parallel to each other, and bear similar extensible pulleys. These pulleys have two cone-shaped members of pressed steel, slotted in such manner that they telescope into each other. The telescoping action varies the effective diameter of the pulley. By an ingenious system of lever connections the two pulleys, one on each shaft, are connected so that as one moves together to increase the diameter, the other spreads apart to decrease its diameter, so that the length of the belt need not vary.

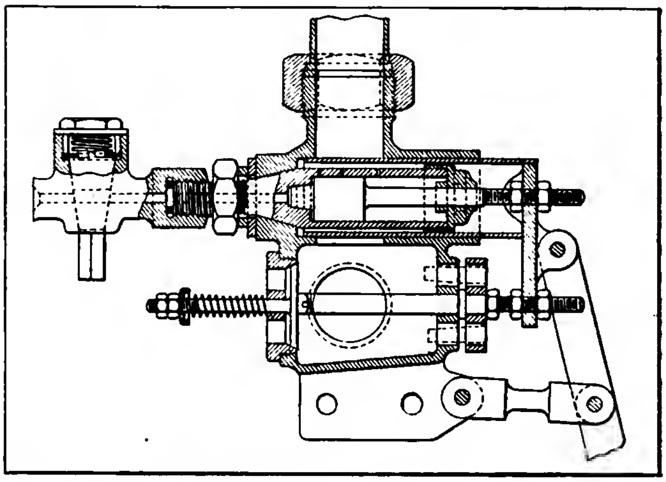
The belt itself is a special construction of raw-hide, triangular in section, and very efficient as a power transmitter. The device yields a wide range of speed ratios, not so complete perhaps as that of the friction-wheel devices, but still wider than that of any standard type of change-gear.

The drawing given herewith, reproduced from *Der Motorwagen*, shows the application of this transmission to a comparatively high-powered four-cylinder car. In order to allow an ample distance between the centers of the shafts, these have been set at an angle, the motor lying diagonally in the car. There seems to be no objection to this arrangement, strange though it looks, except that the motor might be difficult to crank. In the drawing the car is shown on its highest gear ratio, the drive shaft turning at about three times the speed of the motor shaft; this of course necessitates a big reduction in the bevel gears on the axle. For the lowest ratio the arrangement is reversed, and the drive shaft turns at one-third motor speed.

Miesse Horizontal Air-Cooled Aero Motor

This motor, the product of a prominent Belgian firm located at Brussels, was illustrated in The Automobile, issue of March 3, although it was not possible to secure a description of it at that time. It is distinguished by the horizontal position of its cylinders, which are four in number, opposed in pairs; by its system of air-cooling, and by its concentric valves actuated by a single cam.

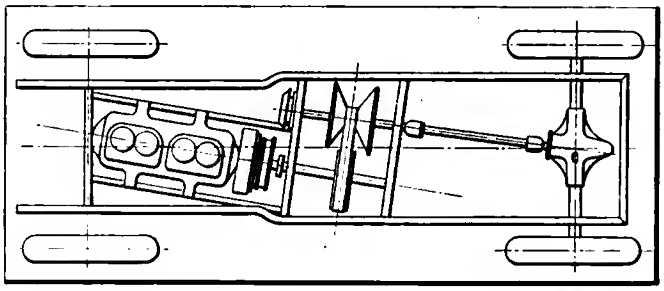
Cylinders are 120 mm. bore by 160 mm. stroke, and the motor is claimed to develop 60 horsepower at 1,200 r.p.m.; the weight



Jaugey Floatless Carbureter, Attached in Any Position

is given as 90 kg. (198 lbs.). The crankshaft is of the two-throw type. The air-cooling feature will be familiar to American readers, at least in principle; it differs from any present examples, however, in using a separate centrifugal blower for each cylinder. The four blowers are located on top of the crankcase in pairs, each pair on a shaft driven by spur gears from the camshaft, and connected with its cylinder by a separate pipe. The cylinders are provided with longitudinal cooling fins and a sheet-metal jacket; the air enters at the top, around the valve seats.

The concentric valves are so arranged that the inlet is the outer one and the exhaust the inner. The arrangement by which they are operated from a single cam is particularly ingenious. The inlet valve, of a cylindrical shape with the exhaust passage through its center, has no apparent connection with the actuating mechanism. There are really two exhaust valves, on the same stem, arranged so that when the lower one closes the lower end of the inlet valve sleeve, the upper one leaves the upper end wide open, and vice versa, or both can be half way open at the same time, thus leaving a through passage. During the compression and explosion strokes the lower exhaust valve is seated. During the exhaust stroke the valves are in the half-way position. At the end of the exhaust stroke the valve stem moves still further down, bringing the lower valve wide open but closing the upper one, and so shutting off the passage. Upon a further downward movement the upper exhaust valve, bearing down on its seat on the inlet valve shell, forces the latter open, and so the cycle is completed.



Sketch in Plan of Fouillaron Belt-Drive Transmission

Hydraulic Transmission Details

Editor THE AUTOMOBILE:

[2,206]—Having read in a recent issue of an hydraulic motor gear, I am very anxious to get more details, and also some statement as to its future possibilities. I would therefore appreciate seeing something on this subject under letters.

Boston. HAROLD W. PIERCE.

There are, broadly speaking, two hydraulic transmissions now on the market in an operating form, one English, the Torbina, the other American, the Manly. The former was described in THE AUTOMOBILE of March 3, page 467, while the latter was described in two separate issues for Dec. 10, 1908, and Feb. 4, 1909, page 243.

The latter has just been adopted by the American-La France Company for use on all of the commercial and fire service motor wagons made by them.

As to the possibilities, one can only estimate, in which one man's unfavorable opinion is as good as another's favorable one: The advantages claimed are elimination of the clutch and transmission, as well as the operating means for both. Moreover, the ordinary transmission permits but three or at most four speeds, all others being secured by a variation in the running of the engine. With the hydraulic transmission, on the other hand, an infinite number of speeds may be obtained, allowing the engine to be run at a constant speed, at which it is more efficient.

Purifying Still of Large Size

Editor THE AUTOMOBILE:

[2,207]—I am much interested in the subject of water purification, in particular for use in automobile cooling systems, and want to ask you something about it. Would it cost much to build or have made a fairly large distilling apparatus in order to purify and soften your own water? I was much interested in the letter on this subject in last week's issue of "The Automobile," but want a large sized one so not to be bothering all the time.

Albany, N. Y. CARL COYLE.

Below is shown a sketch of a large sized still, as promised last week, which can be made, that is, the metal parts, by any tinsmith. The boiler, if it may be so called, is of any sheet metal, providing it has a heavy bottom to stand the repeated heatings well. It has at the top a filling cap, and an outlet of gradually reduced diameter, which leads the stem up to the top of the condenser. The latter is made from a water-tight barrel, inserted in which is a coil of copper pipes. Copper is expensive, and other metals may be used, but it really is the best for the purpose. The barrel is filled with water, and if large enough, one filling will suffice for a whole season's use. The size of the still should be such as to make more than a radiator full at one operation.

All Dry Batteries Have the Same Voltage

Editor THE AUTOMOBILE:

[2,208]—Would you be so kind as to give me an explanation of the difference in voltage between No. 6 dry cells and No. 8 dry cells? The ignition on my motor was produced by six No. 6 dry cells (20 amperes), but on account of short duration of same I am now using four No. 8 dry cells (30 amperes). Will the change in the battery affect the coil or cause any damage to the spark plugs? C. L.

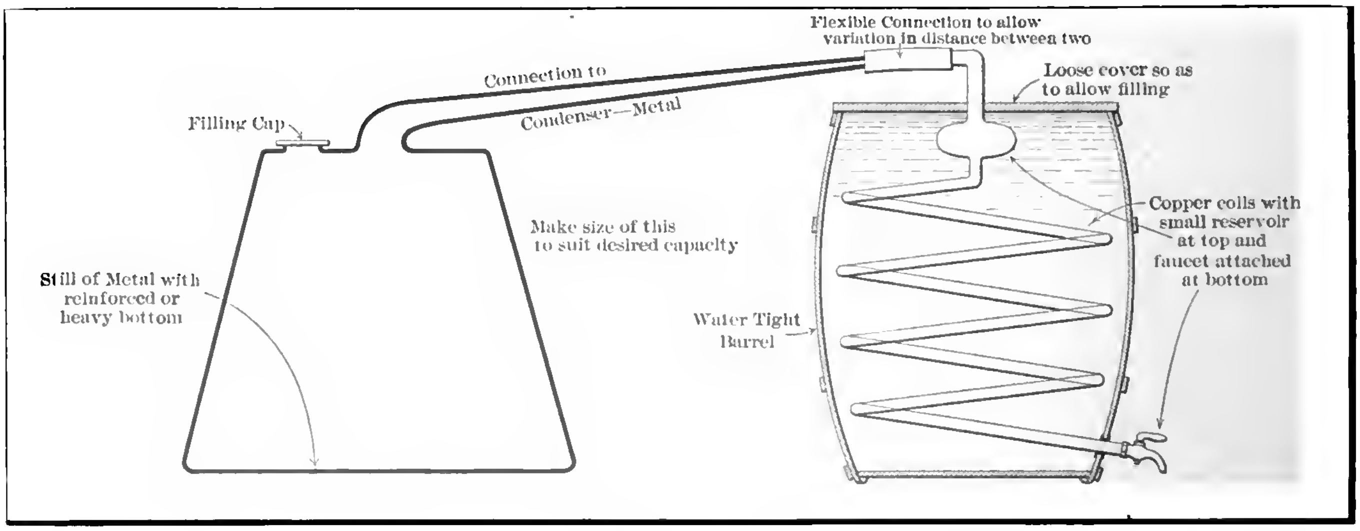
La Crescent, Minn.

The size or number does not make any difference in the voltage of the dry cells. In any sort of battery which produces electricity by chemical action, there is a certain definite difference in potential or voltage between the materials used, regardless of the quantity of the materials.

Dry cells for automobile ignition are commonly wired in series, an arrangement by which the difference in potential of each cell is multiplied by the number of cells. A dry cell, of any size, gives from 1 1-4 to 1 1-2 volts when new, so that with your first set of six cells in series you were getting a total of about 8 volts, and with the present set of four you get 5 to 6 volts. The amperage of the battery, with this wiring, is the same as that of a single cell.

The reason your first batteries did not last long enough was that the amperage was not sufficient. Amperage measures the quantity of the electric current, just as you measure gasoline by gallons. On the same car a 30-ampere battery will last half again as long as a 20-ampere one. Voltage measures the pressure or strength of the current, and 6 volts is about right for automobile work.

No change in the batteries or the current supplied by them will effect the coil in any way, that is, in any detrimental way, all coils being constructed for heavier loads than they are ever called upon to carry. Aside from the coil, which has just been explained, there is no other trouble which may be caused in the ignition circuit, unless it be in the wiring, which may have a very scanty insulation, the latter being so scant as to break down under higher voltages and thus give trouble.



Sketch Showing Component Parts of Large-Sized Still for Purifying Water to Use in Automobile Cooling Systems

ANSWERED AND DISCUSSED

How to Become a Chauffeur

Editor THE AUTOMOBILE:

[2,209]—Will you kindly give me some information on the following matters? I wish to become a competent automobile mechanic and chauffeur, able to drive and repair any make of car, also to handle and repair marine engines. I have not the slightest knowledge at present of that kind of work. How can I most quickly learn this trade, having due regard for thoroughness of training? What wages do men of this class earn usually in the United States? A. D. MACK.

Inlet Baddeck, Nova Scotia.

There are two ways to go about this matter, both of which have some advantages and also some disadvantages. Thus, you can start in with some good automobile school, take a thorough course, then take a place driving a car, being careful to select such a place as will not offer too much difficulty. Beyond that, you will learn much and improve as you go along. This has the double disadvantage of being both slow and not very thorough, moreover, it presupposes a knowledge of mechanical work.

The other method is to go into some factory, and gradually work around from one department to another, staying long enough to learn the part of the work done there thoroughly. When you feel that you have learned all about the making and assembling of the car, then try to get into testing and demonstrating work, which leads naturally to driving. This process, while attended by some large difficulties, is by far the best, and will give better results than any other way. Moreover, factory men are more in demand than school men, and usually get higher wages. The disadvantages are that the factory heads oppose the shifting around so that this process means changing from one factory to another. Moreover, this process is necessarily a long one, covering several years. It has the big advantages of being very thorough, and of bringing in an income while learning, also, as spoken of before, this class of men get more money.

It is very difficult to give you any correct idea of the wages paid, as they vary with the individuals and situations to such a large extent. Some country places, expect to get a good man for $40 a month, with board and rooms. Some city places on the other hand, offer as high as $50 per week for men of the highest skill. As a fair average $25 might be said to cover the large city position, and slightly less the smaller city, and about half that figure for the country. It is said that washers in New York City receive $20 per week, and brass polishers, $13.

Correct Pronunciation for the Autoist

Editor THE AUTOMOBILE:

[2,210]—Will you please give in "Letters Interesting, Answered and Discussed" the correct pronunciation of the following words: chauffeur, chassis, garage? HERRON & SON.

Boyne City, Mich.

As these words have not yet been recognized by the dictionaries, the really correct pronunciation is that of the French, from which they originated. Most automobilists, however, have adopted a half-way pronunciation, about as follows: chauffeur is pronounced "sho-fer," usually accenting the first syllable, but sometimes the second—the latter is regarded as more elegant; chassis is "shass-iss," accenting the first syllable, and garage is "ga-razh" ("zh" like "s" in pleasure), with accent on the last syllable.

Large Wheels Have Many Advantages

Editor THE AUTOMOBILE:

[2,211]—Please give me some information as to what advantage a 36-inch wheel has over a 34-inch, if any. READER.

Malone, N. Y.

Large wheels have in general two advantages; they are easier riding and less expensive on tires. Their easy riding is due to the fact that they do not drop so far into holes, and do not rise so sharply over rocks and humps. A large wheel will bridge across a hole that a smaller one would drop into bodily; and in the same way, being less sharply curved than a small wheel, it meets an obstruction in the road sooner and easier.

In the second place, a large wheel turns fewer times than a small one in traveling the same distance. A 34-inch wheel turns 593 times in one mile, whereas a 36-in one turns 560 times. This, together with the facts above mentioned, makes it less wearing on tires, so that, although the first cost of a 36-inch tire is greater than that of a 34-inch, the large tire will last more than enough longer to make up the difference.

Garage Drainage Problems

Editor THE AUTOMOBILE:

[2,212]—I will appreciate very much any reference you can suggest to assist in gaining information on what is being done in the best practice in the matter of protecting garages from accumulations of explosive vapors in their drainage systems.

Philadelphia. J. HOGELSON.

This is a very important problem and one which the various municipalities have done very little with. The reason why there is so little literature on the subject is concealed within this statement. However, THE AUTOMOBILE has several times published something on the subject, the latest being found in the Dec. 23 issue, on pages 1084 and 1085, the subject of the article being The Private Garage Problem, and the specific matter dealing with the drainage systems required in Milwaukee, and some other municipalities. New York City has a specific law dealing with this subject, copies of which can be obtained.

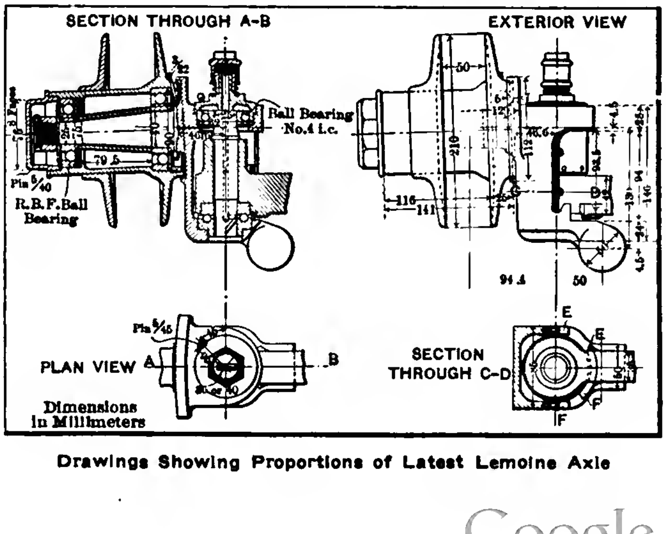
Latest Type Lemoine Axle

Editor THE AUTOMOBILE:

[2,213]—In "The Automobile" which came to hand recently we find that the information you give one of your correspondents in regard to the Lemoine type of axle is incorrect, both as regards the illustration and the description. The type of axle you illustrate was made by Lemoine many years ago before the automobile was the perfected machine it is to-day. This axle is not manufactured at the present time nor has it been for several years. The type of axle known specifically as the "Lemoine type" is that shown in the illustrations enclosed. We will ask you to publish these illustrations in order to correct the erroneous information which your reply conveys. The blue prints we are sending herewith give a very good idea of the Lemoine type of knuckle which can be entirely enclosed to exclude grit and dirt. It is this type of axle for which the Etablissements Lemoine control the patents.

INTERNATIONAL ENGINEERING CO.,

New York City. American Agents; Etablissements Lemoine.



Drawings Showing Proportions of Latest Lemoine Axle

THE LEGISLATIVE SITUATION IN NEW YORK

By XENOPHON P. HUDDY, LL.B.

THE State of New York will have a new automobile law in all probability before the present session of the legislature adjourns. The existing law was passed in 1904 and has remained on the statute books practically unchanged up to the present time. It has served as a model and foundation for motor vehicle enactments in many other States, improved upon, however, in other jurisdictions in many respects. On the whole, the 1904 law has worked fairly well, but the development of conditions arising out of the operation of motor vehicles on the public highways and certain defects in the 1904 law have brought about an urgent need for a new enactment in this State covering the subject. Last year both of the houses of the legislature passed a motor vehicle law which contained no limit on speed except that of reasonable and proper driving. This feature of the bill governing speed was believed to be objectionable and therefore was vetoed by the Governor.

No attempt this year is seriously made on the part of automobilists to have enacted such a broad speed provision. Those who have the best interests of the automobile industry at heart and also the safety of the public, believe that a general speed limitation of this nature would be inadvisable at this time, however many good arguments can be presented in favor of it.

It is very generally conceded that the State of New York needs a new law, but the old law is a great deal better than many bills which have been introduced into the legislature this session. If a better law cannot be passed this year it would be much wiser to allow the old one to remain. In fact, many arguments can logically be advanced in favor of no new legislation. It is always considered an advantage to be working under a known law which has been in existence for several years, inasmuch as everybody is familiar with its provisions and it is not like new legislation which may be discovered to be invalid on account of some mistake. In other words the old law has been tried out and found to be valid. On the other hand, the 1904 law contains many defects, such as, for example, it permits any person to obtain a driver's license, even though he may be blind or a cripple or of immature age. Also the registration and licensing fees are small as compared with those in other States.

It is very generally agreed among automobilists that a reasonable license fee should be paid for the privilege of operating motor vehicles on the public highways, and this license should be renewed annually. In the State of New York to-day $2 is paid for a license and no renewal is required. There is hardly any other State in the Union where automobile travel exists to any extent with so small registration fees, but the objection by automobilists to paying a tax may reasonably and justly be made. There is a vast difference between a license fee and a tax. A license fee is imposed under the police authority of the State which constitutes the power to enact regulations to protect the safety and general welfare of the public. It has nothing to do with the taxing power. The State may do many things under the police power, but just as soon as it attempts to regulate conduct with a view to protecting the public safety by taxation, it is exceeding its constitutional authority. So it should be a principal to be adhered to by all automobilists that the automobilist cannot be taxed for the privilege of using the public highways. Make the iicense fee fair and reasonable so that the State may receive a fair amount of revenue therefrom, but do not make the fee so large that it will constitute an exercise of the power of taxation, which power is the power to destroy, as was long ago announced by the Supreme Court of the United States, in the case of the United States vs. Bank of Maryland.

The main features of a proper automobile law are: to provide a method of identifying offenders, to regulate speed and the operation of automobiles with a view to the safety of the public and to procure revenue. Originally revenue was not considered an essential feature of automobile legislation. Now it is looked upon as one of the main objects. No objection can be made on the part of automobilists to contributing a certain reasonable amount of revenue which is to be applied for the construction and maintenance of roads. That automobiles more or less wear out highways is conceded. Automobilists desire good roads which save their machines and make their tire expenses less. For these reasons automobile users are willing that the registration fees in the State of New York be increased and be made payable annually, but the amount of the fees must not be so great as to make the license charges, taxes.

In regard to the speed of automobiles, this presents a question which is surrounded with more difficulties than any other feature of motor vehicle legislation. Some desire practically no speed limits. Others want very small arbitrary limitations. Then again there are those who believe that we should have a *prima facie* provision, similar to that which exists in the States of Massachusetts and Connecticut. Of course, we cannot have all these and it is merely a question of choosing which is the best. There is very much to be said in favor of incorporating the *prima facie* limitation clause in a speed regulation. For example, if the law provides that 25 or 30 miles an hour shall not be exceeded in the country districts and if a person exceeds this limit it shall be evidence of dangerous driving or a violation of the law. Such a provision would permit the defendant to prove as a matter of fact that no danger was created. In other words, if this provision is inserted, many technical violations of the law would be done away with and undue hardship and oppression would be eliminated. It is very generally conceded by the authorities that automobilists should not be arrested if they exceed the speed limit of 10 miles an hour by a few fractions of a minute. Several of the bills introduced at Albany have raised the speed limit of 10 miles an hour to 15 miles an hour in the built-up sections of cities. This is a wise change, for it has been demonstrated in New York City, for example, that it is practically impossible to comply with the 10-mile rate and that all vehicles exceed this limit. Fifteen miles an hour is a more just rate. In the sections not built up 20 miles per hour can safely be allowed. In the country districts 30 miles an hour is not excessive. Of course, under no circumstances should an automobile be driven at a dangerous rate of speed considering the conditions.

Coming to the question of chauffeurs, we find that a condition of affairs exists which is not at all easy to deal with. Many accidents have been caused by chauffeurs. So also have owners been the cause of collisions and injuries. Whether there should be any distinction between chauffeurs and owners as to licenses to drive is disputable. It is regarded by some that the chauffeur is engaged in a special occupation and for that reason alone he is placed in a separate class and should be subject to regulations different from those who do not make a business of driving for hire. There is much good sense and logic in this argument. On the other hand, it is said that the owner who drives his car can do just as much damage as the chauffeur, and the owner should possess the same qualifications and the same kind of a license as required of a chauffeur.

Whether an examination of automobile drivers would have a tendency to eliminate the reckless operation of motor vehicles and would protect the public better seems to be another question concerning which there is much to be said. Of course, wrongful conduct can never be legislated out of existence. It would seem that an examination might call for physical soundness of a driver and a certain amount of knowledge concerning the safe condition of the machine which he is operating. Beyond these it is somewhat doubtful whether an examination would be of any value. A license to drive, however, should be subject to suspension and revocation for causes not technical. This is very generally conceded.

In regard to penalties, no objection can be made to making them severe for violations which are not purely technical. In the method of arrest and prosecuting automobilists, however, as much red tape as possible should be eliminated. Under the present law in New York an automobilist is arrested, then taken before a police captain where bail must be given, then taken before a police magistrate where a hearing is had, and then bail is given again, then he is bound over to the Court of Special Sessions where he must go to plead and then go again to this court for his trial, where he is often compelled to wait all day until his case is called. After the trial he may depart upon paying his fine if convicted. This process is entirely and altogether too lengthy and annoying. It clogs the courts with unnecessary business, takes the time of policemen and court attendants which might be devoted to more serious and important matters and on the whole it is highly objectionable. It would be very much better to allow the magistrates to dispose of automobile cases forthwith. This view is shared by many judges.

In the enactment of a new automobile law for the State of New York many factions are to be taken into consideration. We have the owners of automobiles, taxicab proprietors, manufacturers and dealers, garage keepers, tire manufacturers and chauffeurs. They are all vitally concerned. Each class has its own ideas about the proper kind of legislation and no two are exactly the same, so whatever law is enacted will be the subject of a compromise to a certain extent. One thing is to be remembered, however, that there does not exist to-day the prejudice against automobiles which former legislators had to contend with, and it is quite likely that when the New York State Legislature has finished its work this session on automobile legislation a very good law will be enacted.

SURPRISING RESULTS FROM NEW TWO-CYCLE ENGINE

RESULTS which will surprise many have been obtained with a new form of two-cycle engine, shown and described at the recent meeting of the A. C. A. at the club house on Fifty-fourth street, New York City. That this subject possesses much of live, human interest was clearly shown in the attendance, which far surpassed any previous attendance for this year's meetings. Not alone were there many in attendance, but they were interested to the extent of digging down into the details, as well as wanting an explanation of the theory. After a brief mention of the latter, J. H. Freeman, who described the engine for the inventor, Mr. Newcomb, told of the advantages to be derived from its successful operation.

This talk was followed by a test, in which the engine, after refusing to start, behaved very well, and showed up in excellent shape. The ordinary form of two-cycle, three-port arrangement is used, but the fuel is injected, preferably from above, by means of a small pump. The latter is driven off of what corresponds to a camshaft on the ordinary four-cycle engine. This may be varied as to height of lift, and also time of lifting, so that the fuel injection may be varied within wide limits. Appended is a test and the results of the same:

NEWCOMB TWO-CYCLE ENGINE

Tests Made at Columbia University

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

Contests will soon be the most conspicuous of autoing events, and much interest will be taken in them. The rules, as promulgated by the Contest Board of the A. A. A., are now in force, and they were revised, apparently with the expectation of being able to eliminate the faults as developed during the past year. The autoing public will readily understand that strictly racing types of automobiles are built out of special materials, under the most exacting conditions, and from designs gotten out by engineers of accentuated skill and experience. The interest of the public in this class of automobiles is passive, and from a sportsman's point of view.

Reliability contests, known as Class "A" in the A. A. A. rules, and other events, which are supposed to bring out the capabilities of "stock cars," interest the autoing public on an entirely different basis. These events are supposed to test the capabilities of the cars, and are claimed by the contestants to represent the way by which purchasers will be enabled to observe performance, and thereby have the means at hand for the purpose of separating the sheep from the goats.

It is to be hoped that the rules as they are now in force, will make it impossible for any unfair contestant to use special racing magnetos on so-called "stock cars," or other devices which will increase speed and endurance beyond that which may obtain in the regular stock cars of the same make. The only fair way of trying out stock cars is to use them as they are regularly put out, and to forbid the use of special magnetos, ball-bearings, carbureters, tires, materials in general, and methods. The mere fact that two cars look alike, come out of the same plant, and in general are made from the same drawings, does not make them alike. Purchasers of automobiles, if they are inveigled into the belief that a car as it enters a stock contest is a stock car, if it is not, will ultimately look upon every contest as the device of the unscrupulous, and the honest makers of real automobiles will be made to suffer accordingly.

It is not enough to dismiss this subject when it is brought to the attention of the proper board, with a wave of the hand, and a statement that the rules had been complied with. An unscrupulous act is rendered none the less so if it is done by rule, and in the long run makers of real automobiles will be compelled, by force of public opinion, to exclude the class of men who enter a special car which is not on a par with their regular automobiles.

* * *

At the last annual meeting of the Society of Automobile Engineers it was pointed out by President H. E. Coffin, in his inaugural address, that motor building, as a science, is in the primary grade. Glancing over the industry, and examining critically beneath the surface, seems to bear out President Coffin's contention. There is undoubtedly a considerable amount of activity in the various laboratories in the several plants, much of which is directed against the motors of to-day, with the hope, perchance, that the motors of to-morrow will be better.

The poppet valve of motor has probably reached the maximum of its capability, and tests have shown that it will utilize 20 per cent of the terminal value of the fuel in useful work, and that 80 per cent is lost, either in the exhaust, the water-jacket, noise, or molecular work. This seems to be a poor showing, but the average steam engine delivers about 8 per cent of the thermal value of the fuel used, and the finest engines of this generic type used on ocean liners will scarcely approach 17 per cent as a figure of the thermal efficiency.

Just now the two-cycle fuel-injection motor is receiving its quota of attention, and it promises much. The latest idea is to inject the fuel after the ports are covered, and to vary the time of the fuel injection to suit the running conditions. In this way, it is possible to alter the ratio of the fuel to air, hence vary the power to suit the needs and to employ a very high compression without having to cope with the ills of pre-ignition, since the timing of the fuel, as it is injected into the body of air in the cylinder, may be such as to eliminate pre-ignition trouble.

Earlier designs of two-cycle motors invariably delivered less than they promised theoretically, because a homogeneous mixture was made in the crankbox and was transferred to the cylinders under conditions of bad scavenging. Within the last two or three years attention has been paid to the mechanical arrangements which have to do with scavenging and the performance of two-cycle motors improved wonderfully as a result. It is now claimed that the direct injection of fuel, in addition to the other improvements wrought, will increase the thermal efficiency of automobile types of motors to a material extent. As a further effort in the direction of improvement, one school of engineers is working on two-cycle types of motors, using forms of slide or piston valves, the idea being to afford a more commodious exit for the burned gas, and to time the valve action to suit the specific conditions.

N. Y. Automobile Trade Association Banquet

THE New York Automobile Trade Association gave its annual dinner in the rooms of the Automobile Club of America on Wednesday evening, March 3d. M. Haradon, president of the Association, presided as its toastmaster, and after an elaborate menu, in introducing the speakers, announced that the Association consists at present of sixty-seven firms doing business in the automobile trade in the City of New York, and that the objects of the organization are co-operative tending to uniform garage rates and regulations, and a uniformity in prices. He introduced as the first speaker Mr. Whiteside, assistant District-Attorney, who gave some careful advice to the law breakers, and was followed by Col. Edward Cornell, chairman of the Highways Protective Society, who explained the mission of the Society in its work for good roads, careful driving and proper use of public thoroughfares by all classes of vehicles. He ascribed a majority of the accidents happening to automobilists as due to intoxicants, and in this particular pointed out that the owner is a more dangerous man than the professional chauffeur. Next followed Oliver A. Quayle, Chairman of the Legislative Committee of the New York State Automobile Association, who explained the situation at Albany, and stated that the only two prominent bills before the Legislature both restrict the passage of speed trap regulations by local authorities, and allows the automobilist fifteen miles an hour in cities and villages, with a maximum of thirty miles in the open highways. Quoting statistics of accidents, he found in the City of New York in one year 180 deaths caused by automobiles, 246 by horse-drawn vehicles, 240 persons killed by trolleys. Outside of the City of New York 15 persons were killed by automobiles, 26 by horse-drawn vehicles and 12 by trolleys. The editor of "The Schoolmaster," Creswell MacLaughlin, confined himself to drastic remarks on general political economy and the solemnity of the occasion of which he was a participant. After which John C. Wetmore, introduced as the "Dean of the automobile writers," closed in his usual happy manner. The dinner was well attended and a live interest was shown in general conditions.

Ohio Clubs May Withdraw From A. A. A.

COLUMBUS, O., March 28—An amendment to the constitution and by-laws of the Ohio State Automobile Association, permitting that organization to withdraw from the A. A. A. was adopted at the annual meeting of that organization in this city. During the year there was a gain of 400 members.

The report of the secretary, Dr. A. B. Heyl, of Cincinnati, showed the membership in good standing to be 1,773.

The board of directors elected consists of W. F. Bonnell, Harry L. Vail, Fred T. Sholes, Walter C. Baker, W. H. Wherry, Lyman Lawrence, T. M. Cagwin, George Collister, F. J. Baird, C. J. Forbes, Jr., and Paul T. Lawrence, of Cleveland; C. L. Bonnifield, G. W. Drach, L. J. Merkle, G. W. Cleveland, A. B. Heyl, McKim Cooke, L. S. Colter, Charles Ireland, A. P. Streitman, William Perin and Carl Streit, of Cincinnati; Perin B. Monypeny, C. Roy Clough, Nelson J. Ruggles, Herman Hoster, C. E. Firestone and William M. Frisbie, of Columbus; Harold Sprigg and Philip H. Worman, Dayton; G. E. Mentel, Springfield; W. R. Huntington, Elyria, and James A. Allen, Kenton. Directors from other cities will be elected later.

Harry L. Vail, of Cleveland, was re-elected president; Dr. A. B. Heyl, of Cincinnati, secretary, and L. S. Colter, Cincinnati, treasurer. Perin B. Monypeny, of Columbus, was elected first vice-president; James A. Allen, of Kenton, second vice-president, and Cyrus E. Mead, of Dayton, third vice-president.

Coming Events in the Automobiling World

Mar. 26-Apr. 2...Pittsburg, Pa., Duquesne Garden, Fourth Annual Show, Automobile Dealers of Pittsburg. Frank D. Sauppe, Chairman.
Mar. 26-Apr. 2...Montreal, Automobile and Motor Boat Show, Official Motor and Sportsmen's Show Committee of the Automobile and Aero Club of Canada, in the Coliseum. E. M. Wilcox, Manager, 123 Bay St., Toronto.
Apr. 6-9..........Watertown, N. Y., Automobile Show, Watertown Automobile Dealers' and Manufacturers' Association, in the State Armory.
Apr. 9-16.........Elmira, N. Y., State Armory, Automobile Show, Elmira Chamber of Commerce.
Apr. 11-16........Harrisburg, Pa., Kelker Bldg., Automobile and Sportsman's Show, Harrisburg Automobile Dealers' Association. B. R. Johnson, Manager.
Apr. 11-16........Erie, Pa., Meyer Block, Automobile and Motorcycle Show.
Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.
Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.
Jan. 17-24, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Feb. 13-25, 1911..Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

Apr. 6-9..........Memphis, Tenn., National Aviation Meet, Aero Club of Memphis (member Aero C. A.).
Apr. 8-10 & 13-17.Los Angeles, Cal., Inaugural Meet, Motordrome.
Apr. 30-May 2...Philadelphia, Roadability Run to Atlantic City, Quaker City Motor Club.
May 2............Flag to Flag Endurance Contest, Denver, Col., to City of Mexico.
May 5-7..........Atlanta, Ga., Track Races. Atlanta Automobile Association.
June 11..........Wilkesbarre, Pa., Annual Hill Climb Up Giants' Despair, Wilkesbarre Automobile Club.

Foreign Shows and Races

Mar. 19-Apr. 3...Berlin Automobile Show.
Mar. 22..........Elegance Competition at Monte Carlo.
Mar. 27-Apr. 4...Prague, Austria-Hungary, Automobile Show.
Mar. 28..........Brooklands, England, Easter Meeting.
Mar. 31-Apr. 8...French Spring Wheel Competition.
Apr. 2-24.........Turin, Italy, Automobile Show.
Apr. 27-28........Brooklands, England, Two-Day Meeting.
May 1-Oct. 1......Vienna, Austria-Hungary, Automobile and Aviation Exposition.
May 28-June 9...St. Petersburg, Russia, Automobile Exhibition.
June 2-8.........Prince Henry (German) Touring Competition.
June 13-18.......Scotland, Scottish Reliability Trials.
June 20..........French Voiturette Race.
June 21..........French Stock-Car Race.
June 22-July 5...Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.
June 27..........Speed Trials at Kiev, Russia.
July 12-18........Ostend, Belgium, Automobile Week.
July 20-25........Boulogne, France, Automobile Week.
Aug. 1-15.........Ardennes, France, Meeting.
Aug. 15-Sept. 15.French Industrial Vehicle Trials.
Aug. 21..........Salon, France, One and Five Kilometer Trials.
Aug. 28..........Mont Ventoux, France, Hill Climb.

"SECRET TIME" TO LEVEL EXPERT AND NOVICE IN RUN

THE third annual Roadability run, under the auspices of the Quaker City Motor Club, will take place Saturday, April 30. The start will be from the club rooms, Hotel Walton, Philadelphia, and the course will be by a roundabout route to Atlantic City. The run will be made according to the rules and approved supplementary regulations of the A. A. A., and with the endorsement of the Philadelphia Automobile Trade Association, in co-operation with the Board of Trade and municipal authorities of Atlantic City.

It will be open to all pleasure cars and under the plans formulated by Secretary H. C. Harbach of the Quaker City Motor Club, unusual interest is given the affair. The handicapping rules are unique, in that the winner of the first prize may finish anywhere in the procession and the first car past the finishing line may earn one of the least of the awards. This unusual condition is created by the selection of a certain definite but secret time for the run and awarding the highest prizes to the cars that most closely approximate that time. The secret time will be within the legal speed limit of the State of New Jersey and will be fixed by Mayor John E. Reyburn of Philadelphia and his confrere Mayor Franklin P. Stoy of Atlantic City.

By adopting such a plan, the club has placed a penalty upon illegal speed and has equalized the chances of the fastest cars with those of more moderate speed and power. In addition to five principal prizes which will be of sterling plate, 160 approximation prizes have also been provided.

The object of the run under the conditions is to afford a contest in which the novices and owners of private machines will be upon the same plane as the experts and professional chauffeurs.

Each car is required to carry two or more passengers. At the conclusion of the run, the cars will park on the Million-Dollar pier, where trophies will be awarded and prizes distributed.

An impromptu auto show will be held after the awards have been made. Last year seventy cars finished in the run of the Quaker City Motor Club and this year a material increase in that number is expected, as 165 prizes have been prepared.

The return trip may be made at the convenience of the contestant, as the jurisdiction of the club does not extend any further than the finish of the run.

RUSH ENTRIES FOR LOS ANGELES MEET

LOS ANGELES, Mar. 27—The track board at Playa del Rey has been completed and a number of the drivers who are going to compete at the April meeting tried out their cars on the new saucer, during the past few days. The finishing touches were put upon the track surface, when the boards were treated with a powdery coat of crushed shell. Great speed was attained by some of the cars and the drivers are enthusiastic about the prospects for a successful meeting.

Among the entries made during the week are those of an Isotta car, by J. B. Marquis and a Reo Bird, by Bruno Siebel; three Marmon cars which will be driven by Ray Harroun; a Corbin, by Al Livingston; two Appersons by Harold Hanshue; a Cole "30" by William Endicott and a Darracq which will be driven by Ben Kerscher. In addition to the entries of De Palma, Robertson, Oldfield, Lescault, Bragg and Hearne, this list makes a formidable appearance. There are also prospects of entries of several more Fords, Buicks, a Velie, Sterling, Stearns, etc.

An interesting feature of the meeting will be the appearance of several of the speed marvels of the past, among which are old "999," the famous racer of Henry Ford that held world's records, which will compete in the free-for-all classes and "Whistling Billy," the White steamer which marked a step in the development of automobile speed under the guidance of Webb Jay. This car has been reconstructed and on the board saucer, its trials have demonstrated that it still possesses the same brilliant speed that dazzled race-goers years ago.

Three concrete subways give entrance to the inside of the track and with a 300-foot paddock, grandstands and bleachers, the accommodations for the public are ample.

A point has been raised that the board surface of the track will become oily from the slopped lubrication of the cars and that the curves might be dangerous. The management, however, declares that the construction of the saucer has been so framed that this danger is minimized and that the coating of pulverized shell will take up any amount of oil that is likely to be spilled by the racers. In addition to its use as a motordrome, the track has been equipped with aerodromes and the Aero Club of California will make it its official headquarters.

DECIDE ON ROUTE OF GLIDDEN TOUR

A meeting of the contest board of the A. A. A. has been called for Wednesday, March 30, to determine upon the course of the Glidden tour of 1910. It had been generally understood that the start of the tour would take place at Cincinnati and that its course would be Southwesterly to Oklahoma City, thence Northeasterly to Chicago, but a distinct impression has been given that this route will be changed materially.

Indianapolis has made a strong bid to supersede the Queen City as the starting point and the indications are that its claims will be urged with power and insistence before the board. One reason underlying the contemplated action by the board is the fact that an effort has been made by a manufacturing concern to forestall some of its rivals by anticipating the selection of the Cincinnati route.

The meeting of the board is of much importance as the details of the tour route will be taken up and a definite decision concerning a number of points, that have not been positively settled so far will be made. Cincinnati's claims will be represented actively, but the indications point to a sharp change in the official itinerary.

HARRISBURG RELIABILITY RUN

HARRISBURG, Mar. 30—The Fourth Annual Reliability Contest of the Motor Club of Harrisburg will be held on May 9th, 10th and 11th and promises to be one of the largest and best contests of the year in the East. The route will lead from Harrisburg to Reading to Philadelphia to Atlantic City on the first day; Atlantic City to Sea Isle City to Cape May to Wildwood on the second day, and from Wildwood to Philadelphia to Lancaster and back to Harrisburg on the third day.

The rules which governed last year's contest, modified to meet the demands of the A. A. A., will be used. There will be four classes ranking from price classification and handsome trophies will be awarded in each class. A technical examination will follow the contest and the final ranking of the cars will be made from road records and technical examination. In the last three years the Harrisburg club has conducted contests without a protest and the 1910 contest promises to prove the most successful in the history of the club. Prominent automobile men, including David Beecroft, of Chicago, will serve as officials while the contest will have the support of makers and the A. A. A.

DEATH TAKES PIONEERS FROM AUTOMOBILE BUSINESS

FATHER OF PIERCE-ARROW IS DEAD

BUFFALO, Mar. 26—George Norman Pierce, father of the Pierce-Arrow car and one of the founders of the Pierce-Arrow Motor Car Company, was buried to-day in Forest Lawn. The funeral was held at the home of his oldest son, Percy P. Pierce, at 168 College street. The services were private.

Mr. Pierce died of heart disease at the Lenox Hotel on Wednesday night. He had apartments in the hotel for the Winter, having been in the habit of dividing the year between the Lenox, Sturgeon Point on the Lake Shore, and San Antonio, Tex.

Mr. Pierce was born in Freiendsville, near Waverley, N. Y., 64 years ago and received his education in the public schools and a business college. He married Miss Louisa H. Day of Boston, by whom he is survived, together with eight children.

He began business in Buffalo as a member of the firm of Heintz, Pierce & Munschauer, making refrigerators and bird cages in 1872. From this, the firm diverged into the making of bicycles and tricycles on Hanover street when the bicycle craze swept the world. The Pierce bicycles obtained wide reputation. The motor car began to occupy Mr. Pierce's attention in 1898, work being carried on in the Hanover street plant until 1907.

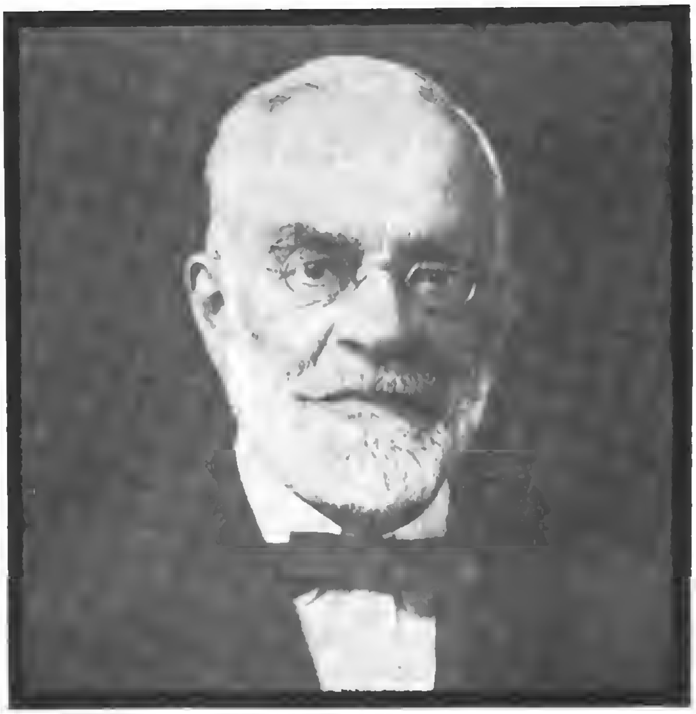
HEART DISEASE CLAIMS J. A. BRISCOE

Joseph A. Briscoe, one of the pioneers in the manufacturing line at Detroit, died last Friday after an attack of heart disease. Mr. Briscoe was the father of Benjamin Briscoe, president of the United States Motor Company and Frank Briscoe, president of the Brush Runabout Company. He was treasurer of the Briscoe Manufacturing Company of Detroit, although for the past two years he had not been actively engaged in business but devoted himself to horticulture.

He was 72 years of age and his whole life had been full of industry and accomplishment. He was the first engineer to take a locomotive into Detroit and has always been identified with engineering and machinery.

He was born at Philadelphia and removed to Detroit when an infant, spending practically his whole life in the Michigan metropolis. In his youth, Mr. Briscoe invented a machine for making nuts and bolts and was one of the founders of the Michigan Bolt and Nut Works, which is still in existence. He was also connected with a large iron mill at Sharon, Pa., and in the later years of his life engaged in the insurance business, being at one time agent of a life and accident insurance company.

George Norman Pierce, Founder of Pierce-Arrow Motor Company, formerly the George N. Pierce Co., who is dead at Buffalo, N. Y.



Joseph A. Briscoe, father of Benjamin and Frank Briscoe, and himself treasurer of the Briscoe Mfg. Co., who is dead at Detroit

FIRST ANNUAL BANQUET OF A.L.A.M. APRIL 7

Amid sumptuous surroundings, the first annual dinner of the A. L. A. M. will be held April 7 at the Hotel Astor. The function will be most elaborate and it is expected that a gathering, thoroughly representative of the manufacturing industry will assemble.

Governor Fred N. Warner of Michigan will be one of the speakers, his acceptance of the invitation tendered him having been received Tuesday. William H. Edwards, head of the street cleaning department of New York will also make an address as will Arthur Brisbane and Col. Charles Clifton, president of the association.

Job Hedges, noted for the quality of his after-dinner speeches will act as toastmaster.

The list of speakers represents a wide field and as considerable latitude is allowed in the choicc of subjects, the oratorical program is attracting much attention among the members of the association.

It is expected that 200 will be present, the attendance being limited to three representatives from each of the concerns identified with the association.

Acceptances have been coming in at a satisfactory rate and a special effort is being made to make the occasion notable.

LATEST DOINGS OF THE A. A. A. CONTEST BOARD

THE Contest Board of the A. A. A. held an important session March 29, at which a number of matters of interest came up for action.

It was decided to sanction a race meet on the Indianapolis Motor Speedway, May 30, under the title of the National Stock Car Championship Automobile Race Meet.

This event follows the Grand Circuit meeting at Indianapolis, May 27-28, and will be the first time that stock cars will contest under the new rules of the A. A. A. All classes of stock cars are eligible to entry in one or more of the races, which will number fifteen.

Gold medals will be awarded the winners in each race; silver medals to the seconds, and bronze medals to the cars that finish third.

Owing to the fact that the races will have a national character, special care has been observed by the board in preparing the details of the rules.

It was definitely decided that the Glidden Tour of 1910 will start from Cincinnati in the middle part of June. The rules and entry blanks for the tour have been finally approved.

In view of the friction that has sometimes followed various events held under the jurisdiction of the board, owing to varying constructions placed by local officials upon the rules, the board decided to issue printed instructions to its representatives all over the country, so that rulings might be more uniform.

The board certified the record of Oldfield at Daytona, in which he broke the beach record for the mile, flying and standing starts; the kilometer flying start, and the two-mile flying start.

The appeal of the Columbia car, which finished second to the Pennsylvania entry in the tour from Los Angeles to Phœnix, which was concluded with a race at Phœnix, was sustained, and the purse of $500 was awarded the Columbia. The question was raised when the wheels of the Pennsylvania car were changed after completing the tour, but before the car took part in the race.

LOUISVILLE SHOW PROVED A SUCCESS

The third annual exhibition of the Louisville Automobile Dealers' Association, which closed Saturday night after holding attention for three days, will go down in the city's history as the greatest event of the kind ever held in this locality and was a fitting introduction to what seems to be destined to be the biggest and best motor year for all concerned. Although the exact figures cannot be had because of the tendency of some dealers to keep their sales secret, officers of the association say that fully 100 cars were sold at the show, representing $200,000. This means that about half of the exhibit changed hands and will soon be speeding up and down the streets of Louisville and the highways of Kentucky.

The dealers anticipate a big month in sales. They say that the show has stirred interest in motor circles ,and that many who could not definitely decide upon a purchase while the show was in progress will do so this month. Many of the dealers have already applied for space in the 1911 show, which will be on a much larger scale than even the exhibition this year.

TRADE ASS'N WILL FIGHT FREIGHT INCREASE

CHICAGO, Mar. 29—Instead of celebrating the opening of the driving season by a week's carnival, the Chicago Automobile Trade Association at its meeting last night decided to substitute a floral parade to be held on the night of May 7. The carnival feature has been postponed until Fall when the dealers will have more time to handle it. The meeting also discussed the threatened 25 per cent increase in freight rates which the A. L. A. M. now is fighting and a resolution pledging the support of the local association was passed and will be forwarded to the traffic department of the A. L. A. M. Fourteen new members were admitted and the association now comprises about 60 of the most prominent concerns in the city. J. B. Maus, manager of the Pennsylvania Tire branch, qualified as secretary, to fill the vacancy caused by the resignation of F. E. Sparks.

PIERCE-ARROW 1911 DELIVERIES

The Pierce-Arrow Motor Car Company, of Buffalo, N. Y., will have its 1911 models, particularly the 6-cylinder 66, so far advanced by the middle of July that a limited number of deliveries to customers who may care to tour abroad are being promised. It is the Pierce-Arrow idea that it is an advantage to thus start delivering in the middle of the touring season, since it affords opportunity to tour abroad in season.

TEN MILES OF LONG ISLAND PARKWAY

By September, ten more miles will be added to the Long Island motor parkway, the clearing, grading and blasting necessary upon the course having been practically completed from Bethpage Lodge to Lake Ronkonkoma. The stretch from Meadow Brook Lodge to Great Neck, which was prepared in 1909 is being given a surface of bituminous macadam and the new work will be treated similarly this summer.

In constructing this section, ten highways are crossed either above or below grade, while steel and concrete viaducts traverse branches of the Long Island Railroad and the trolley line running from Hicksville to Mineola. Two toll lodges have been built, one at Great Neck and the other near Mineola.

The plan that is being worked out in the construction and improvement of this parkway is very similar to the original idea.

PLANS NATIONAL AUTOMOBILE SHOW

Stewart McDonald, general manager of the Moon Motor Car Company, has started a movement in St. Louis to hold a national automobile show in that city for two weeks in the latter part of September, during the National Good Roads convention. The Million Population Club of St. Louis has taken up the plan, which provides for holding the show in tents under the auspices of either the National Association of Automobile Manufacturers or the Association of Licensed Automobile Manufacturers.

HARTFORD DEALERS HOLD ANNUAL MEETING

At the annual meeting of the Hartford Automobile Dealers' Association held Wednesday evening of this week the following officers were re-elected: President, Ralph D. Britton; vice-president, L. H. Elmer; secretary, S. A. Miner; treasurer, Fred W. Dart. Following the election, plans for the show to be held in 1911 were discussed. The present show committee: Fred W. Dart, E. G. Biddle and W. L. Ledger were instructed to look into the matter and to report at the next meeting.

COL. CHARLES CLIFTON HAS RETURNED

Substantially a month ago, Col. Charles Clifton, president of the A. L. A. M., and the Pierce-Arrow Motor Car Company, and Mrs. Clifton, departed for the Carribean Sea and adjacent interesting points, for a rest and recreation, and after an interesting voyage, leaving dull care behind, returned much invigorated, and the pressure which Col. Clifton is accustomed to applying to affairs automobile will be felt again.

UNITED STATES MOTOR COMPANY ABSORBS WINTON

With rumors flying thick and fast as to combinations, mergers and the like, the denials flying fully as fast, the layman is at a loss just what to believe. In the latest report to the effect that the United States Motor Company has acquired the Winton Motor Carriage Company, of Cleveland, there is more of truth than in other stories going the rounds lately; in fact, coming as it does directly from the inside of the acquired concern, it may be taken as a settled fact. With this acquisition, the United States Company holds an enviable position in the industry, due to the prestige which was added to the combination by the subsidizing of Alexander Winton, a pioneer in the automobile industry, and the possessor of an immense and well-equipped plant at Cleveland, to say nothing of a vast and well organized selling organization, with factory branches in New York, Chicago, Boston, Philadelphia, Baltimore, Pittsburgh, Cleveland, Detroit, Minneapolis. San Francisco and Seattle.

Rumors of further mergers of automobile companies have been plentiful during the past week, but so far as could be determined, their foundation is not sound. It was reported rather persistently that the Studebakers had gained control of the Ford Automobile Company of Detroit, but the rumor was definitely nailed by a statement to the contrary by F. S. Fish, director of the Studebaker company and by a general denial of further activities in the merger line, by W. R. Ennis of New York. The home office of the Ford Company also denied the story and branded it as "made of whole cloth." Mr. Ennis said that so far as he knew, there were no more mergers contemplated by the Studebaker interests and their allies in Indiana.

In the meantime Ford is holding the fort and it is said that he is entertaining offers from competent sources, one of which is mentioned as the United States Motor Company, but this rumor cannot be confirmed.

NEW FACTORY FOR BOSCH MAGNETO

Plans for the largest magneto factory in America are being prepared for the new Bosch Magneto Company's plant, which will be erected at Springfield, Mass., this Spring. Several of the preliminary contracts have been let and the work is being rushed along as fast as possible. The factory site at Springfield consists of seven acres and was purchased by the company during the past month.

The buildings will be of reinforced concrete and will be constructed upon lines of most modern development and design. Particular attention has been directed toward sanitary improvements.

ALL-CONNECTICUT RELIABILITY RUN

Hartford, Conn., Mar. 28—Progress has been made by the contest committee of the Automobile Club of Hartford for the forthcoming three-day, all Connecticut reliability run, which is to be conducted under the rules of the A. A. A. Entry blanks to the number of 3,000 will soon be issued and will be circulated about the country generally, it being the intention of the committee to see that each manufacturer receives two blanks.

Entries close Wednesday, May 18, and all cars must report to the technical committee the day before the start of the first day's run, at the club garage.

HAMMOND NOT GUILTY OF LARCENY

Chauncey W. Hammond, charged with stealing $17,000 from the E-M-F Company by switching satchels in the First National Bank of Detroit, Nov. 19, 1909, was acquitted of the charge by a jury in Judge Phelan's court.

The jury deliberated for two hours and took four ballots before the members all agreed upon their verdict.

Hammond is still held on charges of padding payrolls, but the bail on this count is comparatively trifling as compared with that required on the major indictment. Hammond was formerly paymaster of the E-M-F Company but at the time of the loss of the money he was not in its employ.

MUCH BUSINESS IN SIGHT ON COAST

W. A. Paterson, president and general manager of the W. A. Paterson Co., Flint, Mich., is touring California in a Paterson "30." Mr. Paterson is optimistic over the winter's business on the coast, finding the "30" well established in popular favor by reason of its sturdy qualities. Strong evidence of its strength was given last week when the Paterson won out in the annual hill climbing contest at Oakland., one of the most trying tests of the season.

E-M-F DIRECTORS ON STUDEBAKER BOARD

South Bend, Ind., Mar. 25—As the result of the merging of the interests of the Studebaker Brothers Manufacturing Company and E-M-F Company, a meeting of the board of directors of the Studebaker Brothers Manufacturing Company was held at the offices of that company in South Bend on Wednesday and at the invitation of the management, Walter E. Flanders, president and general manager of the E-M-F Company, and Frederick W. Stevens, of J. P. Morgan Company, of New York, accepted the nomination and were elected members of the board of directors of the Studebaker Brothers Manufacturing Company. Both are members of the board of directors of the E-M-F Company.

FIRE DESTROYS TWENTY-FIVE CARS

Camden, N. J., Mar. 28—When the assessor comes around he will have twenty-five fewer automobiles to record as being owned here. A fierce fire in the garage of J. G. Reeves, 106 North Seventh street, last Wednesday morning reduced that many cars to rusty scrap in something less than an hour. Despite the fact that the cars were all stored on the ground floor, the blaze was so intense and the gasoline explositions so terrifying that but one car could be removed, and that was used by an employee to summon the engines. It is estimated that the loss was $75,000.

SWANN BILL PASSES SENATE

Baltimore, Mar. 27—Decorated with a number of amendments, the Swann motor vehicle bill has been passed by the State Senate and will now be thrashed over in the House. The chief change in the measure as it stands is a provision to allow the city of Baltimore one-fifth of the revenue from licenses, after the running expenses of the Automobile Commissioner have been paid. This revenue is to be applied to street improvements.

MOTORISTS FAVOR NATIONAL LAW

Chicago, Mar. 28—Pressure is being brought to bear upon Congressman James R. Mann, of the First District of Illinois, by the Chicago Motor Club and other automobile interests to influence a favorable report on the Federal Registration Automobile bill, now pending before the Interstate and Foreign Commerce Committee.

PARKER GEAR WILL BE MANUFACTURED

It is learned that the Parker transmission which was illustrated in The Automobile recently, will be manufactured by the Parker Transmission & Appliance Company, now located at Springfield, Mass.

Krit Car Won First Place in Event One

After the Races, Crowd Starting Home

White Star, a Home Product, Also a Winner

EMF, *Cohen* Up, Won But Was Disqualified

Oldknow in a Buick Winner of Event Four

ATLANTA, GA., Mar. 26—Although there were fewer entries and fewer starters in the Atlanta hill climb this year than last, and though the crowd was smaller and the marks slower, it was none the less a creditable affair and the time for the .88 mile made by A. R. Almand, driving Ed Inman's Simplex car, 47 4-5, was the fastest ever shown by a gasoline car on the hill. The mark of 45 4-5 made last year by a White Steamer still stands and is likely to for some years to come.

The names of Strang and Burman, which conjured crowds of large proportions to the Stewart Avenue hill last Spring, were missing from the lists of drivers. Only local men took part in any of the events, although several of the factories had mechanics on hand to see that the cars were in good trim.

As has ever been the case with events held in Georgia, the course was policed in a most excellent manner, the crowds stayed where they belonged and there was nothing which bore the faintest possible resemblance to an accident.

The climb was set for 1:30 and everything was in readiness then but the timing apparatus, a home-made contrivance that worked well last year and that showed real class in the preliminary warm-ups this year. At the critical moment it quit utterly and after an hour of tinkering it was given up as a bad job and the cars were timed by stop watches at the top and with the aid of a telephone which, fortunately, remained in working order.

The wrestling match with the timing apparatus consumed an hour and at 2:30 the first of the little cars got away in the baby class and thereafter they were run up rather steadily; but it was well on toward dark before the Simplex came whirling up, the last car to climb and the winner in the free-for-all.

The Krit and the Hupmobile had things their own way in the class for cars costing $800 or under, owing to the fact that the Flanders arrived too late to take part. Of these the Krit had made the better time in practice, showing 1:18 and though it could not approach this mark in the climb it made 1:25 which was good enough to win. The first time the Krit came up there was bad team play on the part of the timers and it had to make a second run, which it did successfully.

Class 2 had a goodly number of entries and starters but it was hardly a close contest, for the Buick showed 1:07 right at the start and spoiled the fun. Nearest to it came the Warren-Detroit which made a mark of 1:15 1-5. A Ford was third.

Class 3 was the only one enlivened by a protest. In this event the E-M-F burned out its wiring a few minutes before it was time to start. Another E-M-F was accordingly borrowed and made the lowest time in the class, 1:15. It was disqualified, however, for being shy a few stock parts, including a lamp and a dust pan. This disqualification gave first place to a White Star, an Atlanta-made car, which consumed 3-5 second more. A Buick was second and a Parry third.

In class 4 four of the six starters were Buicks and three of the four were "placed." William Oldknow's car, which came through the New York to Atlanta run with a perfect score, was first in this event with a mark of :57 2-5. This was the best time

Hill Climb

Some of the Interested Spectators

With the Officials at the Starting Line

of the day in any class except the free-for-all and was better by 3-5 seconds than Strang's remarkable time of last season.

In the free-for-all there was never much doubt but that Ed Inman's Simplex would prove the winner, for it outclassed the rest of the field in power; and won in handy style. A. R. Almand, winner of the free-for-all two years ago, was at the helm.

A 40-horsepower Knox, the identical one that cost a life last year at Indianapolis, was a neat second, making the climb in 50 1-5 seconds, with John F. Toole, winner of the first local free-for-all, at the wheel. A National was third and a Pope-Hartford fourth. The summary follows:

The summary follows:

CLASS 1—Cars Costing $800 and Under.

Pos.—Car	Entrant	Driver	Time
1 Krit	Kelly-Knight Co.	C. F. Woolfe	1:25
2 Hupmobile	E. D. Crane & Co.	K. T. McKinstry	1:31
3 Metz	Dixie Auto Co.	D. R. Miller	3:43

CLASS 2—Cars Costing $801 to $1,200

1 Buick "10"	Buick Motor Co.	L. E. Fain	1:07
2 Warren-Detroit	Carmichael Co.	J. E. Darby	1:15 1-5
3 Ford "T"	Carolina Cement Co.	M. W. Venable	1:19
4 Mitchell "R"	Howard Co.	R. C. Howard	1:26 3-5
5 Cameron "16"	Dixie Auto Co.	G. F. Hardy	1:31
6 Cameron "15"	Dixie Auto Co.	J. B. Wall	2:16

CLASS 3—Cars Costing $1,201 to $1,600

1 White Star	Atlanta Car Co.	C. E. Jones	1:15 3-5
2 Buick "19"	Buick Motor Co.	P. O. Parmalee	1:18 2-5
3 Parry "35"	Capers Car Co.	P. C. Shultz	1:28 3-5
E-M-F "30"	Georgia Car Co.	H. L. Cohen	disqualified

CLASS 4—Cars Costing $1,601 to $2,000

1 Buick "16"	Wm. Oldknow	Wm. Oldknow	:57 2-5
2 Buick "17"	Buick Motor Co.	P. O. Parmalee	1:02
3 Buick "16"	Buick Motor Co.	L. E. Fain	1:03 2-5
4 Pullman "O"	Pullman Co.	R. T. Peckham	1:13
5 Buick "17"	W. E. Wimpy	T. B. Dial	1:15
6 Inter-State	Inter-State Co.	A. R. Brown	1:15 3-5

CLASS 5—Cars Costing $2,001 to $3,000

1 National	W. J. Stoddard.	W. J. Stoddard	:58
2 Knox "M"	J. F. Gatins, Jr.	L. W. LaBlanche	1:07 1-5
3 Marmon	W. T. Candler	W. T. Candler	1:09 2-5
4 Pope-Hartford	A. W. Kirk	A. W. Kirk	1:13
5 Selden	R. F. Ingram	Roy G. Young	1:20 2-5

CLASS 6 and CLASS 7—Cars Costing $3,001 and Over

1 Packard	J. D. Rhodes	C. C. Rooney	1:04 4-5
2 Stearns	W. T. Dunn	W. T. Dunn	1:05 3-5

FREE-FOR-ALL

1 Simplex	E. H. Inman	A. R. Almand	:47 4-5
2 Knox	Georgia Knox Co.	John F. Toole	:50 1-5
3 National	W. J. Stoddard	W. J. Stoddard	:55 1-5
4 Pope-Hartford	Steinhauer & Wight	A. R. Almand	1:03 1-5

SAVANNAH ENDURANCE RUN POSTPONED

SAVANNAH, GA., Mar. 28—The endurance run of the Savannah Automobile Club, which was scheduled to take place on March 28 and 29 has been postponed to April 5 and 6. This run, which will be from this city to Jacksonville, Fla., is already attracting attention in all parts of the country. The run to Jacksonville will take two days and will, when complete, form the last link in the great highway route between New York and Florida.

National Which Won First in Class Five

Roades, in Packard 30, Made Very Fast Time

Simplex, Almand Cleaned Up in the Free For All

AMONG THE GARAGES

Correja 35-horsepower runabout, which makes its initial appearance in New York City under the management of J. Mora Boyle, at 1851 Broadway. It is made in Elizabeth, N. J.

George M. Schebler, of Wheeler & Schebler, Indianapolis

Baack, Reed & Gage Company, a new garage and agency concern at Janesville, Wis., has absorbed the Roy Pierson garage. The Pierson garage on South Main street, Janesville, will be abolished and all business will be done from the large new building owned by the Baack, Reed & Gage Co. on North Main street. The building has dimensions of 45 by 125 feet, three stories high, strictly fireproof and is one of the best of its kind in southern Wisconsin. Roy Pierson is retained as sales manager.

Thomas J. Northway, 92-94 Exchange street, Rochester, N. Y., where he is selling Fords and Oldsmobiles, is building a three-story structure at 100-2-4 Exchange street which he hopes to occupy this summer. The new building is 54 by 140 feet with three stories and basement. It will be of fireproof brick construction with a big show room in the front half of the main floor. The back half will be a garage. The second floor will be a paint and repair shop, and the third, a machine shop.

The Waynesboro Garage Company, of Waynesboro, Pa., has voted to increase its capital stock from $10,000 to $20,000 and to apply for a Pennsylvania charter. The money will be used to equip the old market house as an up-to-date garage. Dr. D. B. Sniveley, Dr. P. D. Hoover, Dr. C. W. Baerd, D. L. Miller and W. H. Smith constitute the building committee. The Garage Company now has a membership of over fifty.

The Central Automobile Company has leased the garage at 6112 Broad street, East End, Pittsburg, and will use it for a distributing station. P. W. Newell is president and A. E. Corns is secretary and treasurer of a new company which has established a central garage on South Gallitzin avenue, Uniontown, Pa. They will handle the Elmore car.

The Reimers Motor Car Company, of Louisville, Ky., has assumed the agency of the Babcock Electric Company. A garage, which will cost $15,000, and which is to be equipped with facilities to handle electrics as well as gasoline cars, is being built for the company, and the expectation is that it will be completed in April.

The Roe-Halverson Auto Co., of Stoughton, Wis., has leased part of the Peterson blacksmith shop on Main and Fifth streets, Stoughton, and this is now being converted into a garage. In addition to this, the company has a large warehouse two blocks away. The new quarters will be used for offices and repair shop.

Judge Dodge, of the Elkhart, Indiana, County Circuit Court, has appointed Milo W. Stark receiver for the Elkhart Garage Company. The complaint declares the company owes $7,000, and has $3,000 in assets. The receiver was granted permission to continue business for thirty days.

Extensive additions are being made to the sales rooms and garage of the Central Ohio Motor Car Company, 61 East Spring street, Columbus. The office has been moved to the second floor, giving more space for showing automobiles. The repair shop is also being enlarged.

At Clarkville, Ohio, the Kilpatrick French Automobile Company has purchased a lot at Broadway and South street, where a $12,000 garage and salesroom will be erected. The building will be two stories high and will have a large repair department in the basement.

The Taylor-Prior Company of Eau Claire, Wis., representing the Stevens-Duryea, has commenced work on its new garage on South Barstow street. It will be of cement block construction, strictly fireproof and will include a repair department.

Instead of remodeling the former Cary livery stable for the agency of C. J. Edwards at Appleton, Wis., the Cary estate has started work on a large new building especially for garage purposes. It will be completed about May 1.

The Homestead Automobile Company has completed its garage at 209 Seventh avenue, Homestead, Pa., and will handle the Franklin and Rambler cars. M. W. Coulter is president and manager.

The Hopkins Motor Car Company, of Clinton, Ia., will open a garage in the Shoecraft Building, at First street and Fifth avenue, that city. The company handles the Jackson and Fuller.

The City Motor Car Company, recently organized in Houston, Tex., has let the contract for the erection of a two-story brick garage at Caroline street and Texas avenue, to cost $15,000.

Cliff Garrison and Peter Young have opened an auto livery at Kent, Ohio, with several cars in service.

Men Prominent in the Trade

Fred Haumerson, of Fort Atkinson, Wis., for several years associated with the Mitchell-Lewis Motor Company, of Racine, Wis., has been appointed field expert of that company.

Frank L. Black, recently connected with the Diamond Rubber Company as salesman in Boston and vicinity, has joined the sales force of the Boston branch of Morgan & Wright.

E. L. Moore, for seven years in the advertising department of the Cleveland *Plain Dealer*, has succeeded W. S. Gilbert as automobile editor of that publication.

Webb Jay has joined the forces of the United States Motor Company and will act as assistant district manager at Chicago.

Carl Van Seiver, Cleveland agent for the Randolph truck, has moved to new quarters in automobile row at 1526 Euclid avenue.

J. S. Bretz, of J. S. Bretz Company, importers, is in Europe on a tour in which pleasure is combined with business.

WITH THE AGENCIES

Marmon "Yellow Jacket," built to compete at Los Angeles and other meets during the coming season. It has a six-cylinder motor. Ray Harroun, the successful Marmon driver, is the pilot

Alvan Macauley, general manager of the Packard Company, Detroit

The Keller Manufacturing Company, of Philadelphia, has purchased the business of the W. P. Pressinger Company, of New York, its general eastern distributor and distributor for Michigan, and this territory will hereafter be handled direct by the Keller Manufacturing Company. J. J. Swan, secretary of the W. P. Pressinger Company, will be associated with the Keller Manufacturing Company.

The Firestone Tire & Rubber Company has opened a branch at 442 Van Ness avenue, San Francisco. The company has also established two more general distributing agencies. One is the Fort Wayne Vulcanizing Works, 215 West Main street, Ft. Wayne, Ind., and the other is the Burwell-Smith Auto Supply Company, 416 North Broadway, Oklahoma City, Okla.

The Curtis Automobile Company, Milwaukee, Wis., State representatives of the Reo, which recently took on the Corbin, has been appointed representative of the Hupmobile. A new garage is being built for the Curtis concern on Eighth street, near Grand avenue, opposite the large garage of the McDuffie Automobile Company.

The Euclid Automobile Company, of Cleveland, has been appointed distributor of the 60-horsepower Atlas. The company is already agent for the Firestone-Columbus, Columbus electric and Frayer-Miller truck. Recently the company occupied a large new garage and sales building in the heart of automobile row.

The Toledo Regal Sales Company, of Toledo, Ohio, was incorporated recently, with capital stock of $5,000, to act as agent for the Regal in Northwestern Ohio. The incorporators were William S. MacMurray, H. J. Chittenden, A. L. Trautmeier, William Rather and Charles Rather.

The Anderson Motor Car Company, of Fond du Lac, Wis., is district agent for the Mitchell and Maxwell in a large territory of central Wisconsin. M. M. Anderson is manager. The garage and salesrooms are located at 34-38 West Second street, Fond du Lac.

The Vestal Motor Car Company has secured the Pittsburg agency for the Auto Car, manufactured by the Auto Gas Engine Works, of Philadelphia, Pa., and will exhibit it shortly in the Rittenhouse Building in the East End.

W. A. Eckles has taken the Cleveland agency for the Anhut Six and has opened temporary headquarters in the Citizens Building. A large sales and garage building will be occupied later in the downtown district.

The Tanberg Auto Company, of Eau Claire, Wis., has opened a branch in Chippewa Falls, Wis., at 203 Bridge street. The company represents the Peerless, Winton, Oldsmobile, Buick, Oakland and Waverly electric.

The Asheville (N. C.) Cycle & Automobile Company has shortened its title by eliminating the "Cycle." In future it will be known as the Asheville Automobile Company. There has been no change in ownership.

The Forbes Motor Car Company has secured the Pittsburg agency for the Krit runabout and roadster and also the Abbott-Detroit 30-horsepower, five-passenger car. H. N. Munhall is manager.

The L. J. Gilmer Company of Salt Lake City, Utah, agent for the Empire Tire Company, will hereafter be known as the Utah Motor Car Company. The change went into effect March 10.

Geo. E. Loveland has been appointed Pennsylvania representative for the Kilgore shock absorbers, a Boston-made product, with headquarters at 107 Reily street, Harrisburg.

At Toledo the Atwood Automobile Company has leased the building formerly used by the Dollar Savings Bank, and it is being fitted up as a downtown show room.

The Everitt "30" has opened quarters in Pittsburg, with Edward Bald as manager, and the concern will be known as the Eddy Bald Motor Car Company.

Chas. Strader has been placed in charge of Western agencies of the Keller Manufacturing Company, with offices at Chicago and Lincoln, Nebraska.

J. C. Donahue has secured the Pittsburg agency for the Whiting and is opening a new garage on South Beatty street, East End.

The Tedford Auto Company, of Little Rock, Ark., has been appointed State agent in Arkansas for the Moon Motor Car Company.

The Muhle-Louis Automobile Company, of Cincinnati, was incorporated with a capital stock of $7,500 by H. M. Muhle and others.

The Ideal Electric Company has secured the Chicago agency for the Federal Motor Car Company, of New York, a new concern.

New Packard Company Executive

Alvan Macauley has resigned as general manager of the Burroughs Adding Machine Company to become general manager of the Packard Motor Car Company, of Detroit, succeeding S. D. Waldon, who has been elected vice-president of the Packard Company.

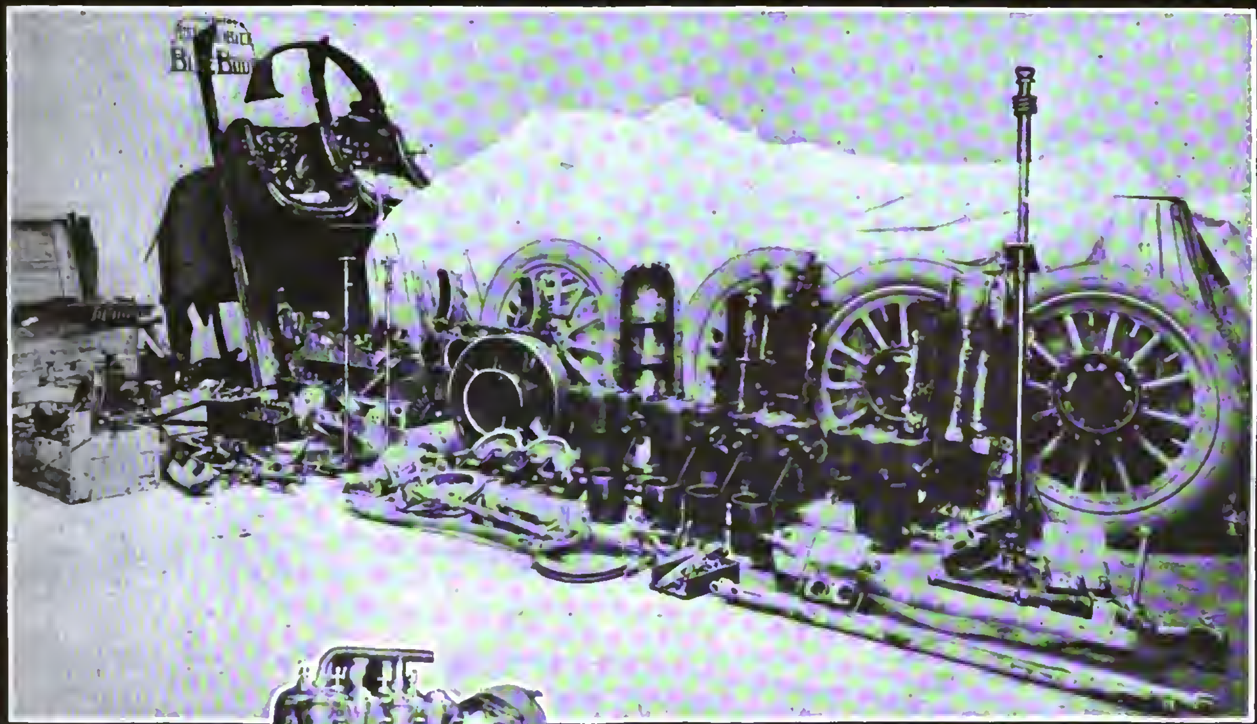
Mr. Macauley has been general manager of the adding machine company for eight and one-half years, and was one of the men responsible for bringing the Burroughs plant to Detroit.

He first obtained prominence in the commercial world as a patent attorney, practising in Washington, but gave up that practice to become associated with the National Cash Register Company, at Dayton, Ohio, which position he occupied for years.

INDEX TO ADVERTISERS

Vol. XXII New York—Thursday, April 7, 1910—Chicago No. 14

THE AUTOMOBILE



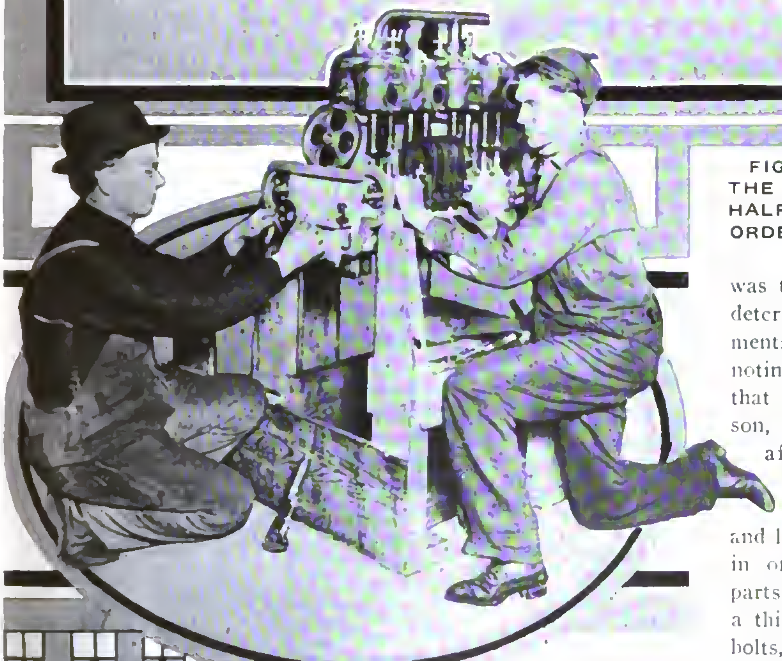


FIG. 1—ORDERLY GROUPING OF THE COMPONENTS OF THE DISSEMBLED AUTOMOBILE. FIG. 2—MARKING THE HALFTIME GEARS AS THEY ARE TAKEN DOWN IN ORDER TO FACILITATE CORRECT REPLACEMENT.

SYSTEMATIC methods produce the best results in a repair undertaking, as well as they do in the manufacture of automobiles. The title illustration of this article shows a 1906 model of a well known make of automobile, after fairly continuous service up to this time, with the exception of a somewhat extended overhauling to which it was subjected last year. In the present undertaking, it was the idea to inspect each part very carefully in order to determine, not only the extent to which repairs and replacements would have to be made, but with a view to carefully noting deformation, or evidences of fracture, and to be sure that the parts should either be abandoned for a definite reason, on suspicion, or be used in the reassembling process after passing a rigid inspection.

It was considered of the first importance to dissemble the car systematically, clean every part thoroughly, and lay them down in proper groups (a) all the motor parts in one group; (b) the transmission gearset and relating parts in another; (c) the members of the control system in a third; (d) the multiplicity of relating members, including bolts, nuts, keys, etc., laid out in systematic groupings, according to their several uses.

In the process of dissembling the car, all the parts were properly marked or so tagged that they were readily identified in the subsequent assembling process, and the halftime gears were spotted and identified so that they were readily put back into place, as shown in the lower figure of the title illustration, thus eliminating unnecessary labor, and the chances of future trouble. It is believed that this careful process of taking the car apart, cleaning all the pieces, and laying them down in a light and accessible place, is likely to have a wider influence on the quality of the work, and the

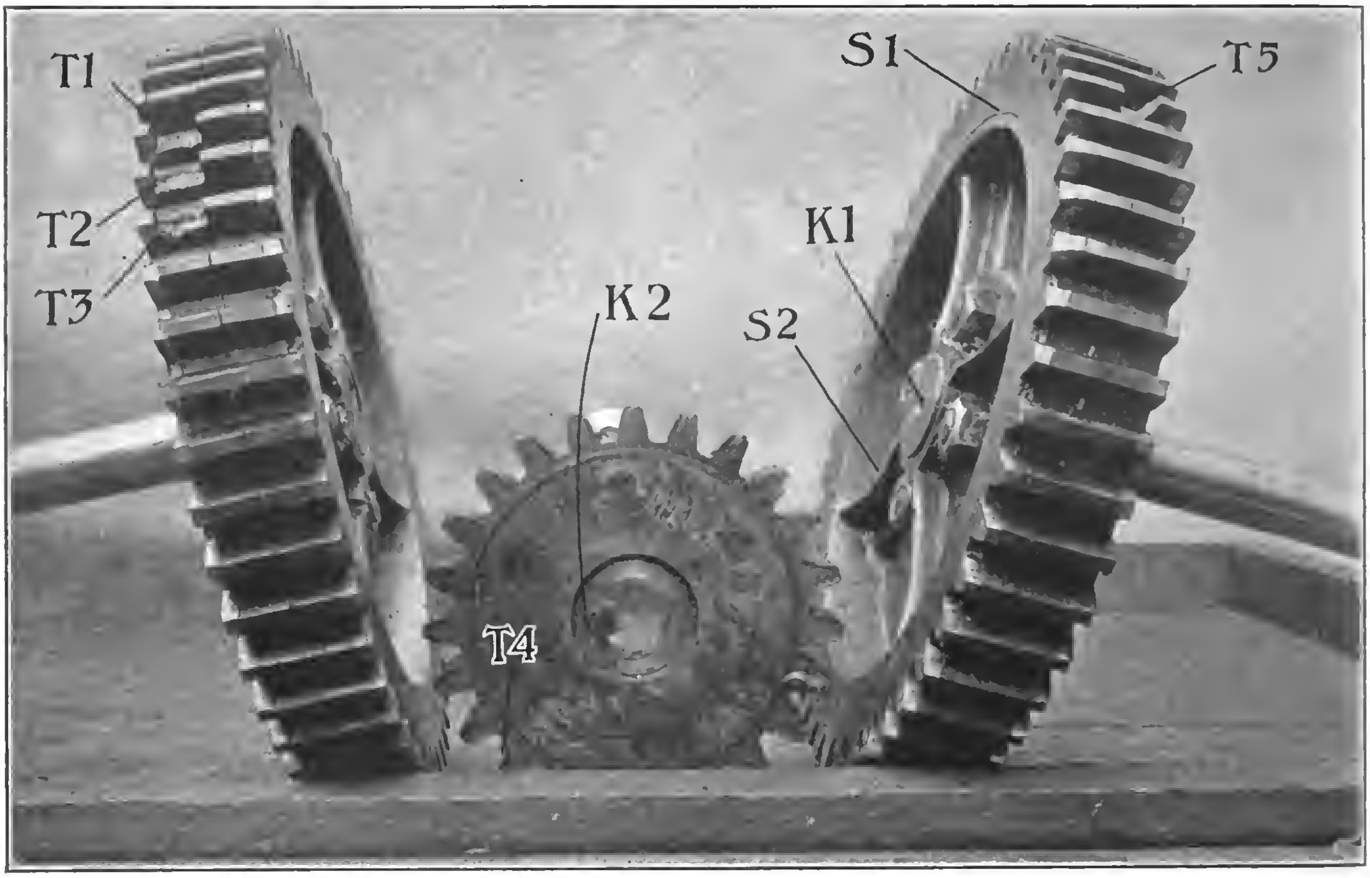

Fig. 3—Halftime gears of shrouded fiber, and pinion of steel, showing condition of the fiber, and the wearing away of the teeth of the pinion

cost thereof, than anyone would readily realize. It costs a considerable amount of money to have skilled workmen searching for lost parts every time they make a move, and obviously in the absence of a system of this sort, all the parts are lost all the time, because if they are not in a definite known place, they have to be searched for when they are wanted.

The average repair man, if he makes a jumble of the parts, is enough of a machinist to reproduce them readily, and it is much more of a pleasant task for him to reproduce a part than it is to make a diligent search in a disorderly arranged pile of parts. Everything in connection with repair work indicates that an orderly array of the members after they are properly cleaned and inspected, is one of the best investments that can be made, and the first principle of good repairing lies buried in this one idea.

SOUND JUDGMENT IS OFFERED A WIDE OPPORTUNITY

Many autoists have complained bitterly of the extent to which they were lead into repair work, which extended beyond their reasonable expectations, and which proved to be unprofitable in every way. When a used car is taken apart and strewed about haphazard, it has a most discouraging look, and the repair man of small skill is likely to reach the conclusion that the parts are substantially worn out, and that new ones will be necessary in order to produce the desired result.

Under such conditions, if the bent of the repair man is to guide the owner of a car, he will have for his pains a new automobile, but he will have purchased it drib drab fashion at an enormous cost. A new car, direct from the maker, will have many advantages under such conditions. Obviously, a good repair man will be an optimist under such conditions, and instead of running off to the maker of the car for enough new parts to satisfy the situation, he will interject a fair measure of ingenuity and avoid in every possible way, the purchase of new parts.

If replacements must be made, it is far cheaper to order them directly from the maker of the car, than it is to reproduce them in a repair shop. The workman is paid by the hour; he will not be able to reproduce the parts until the material is procured, and whether or not he goes after the material, or sits around waiting for it is to be brought to him, is a matter which results in cost, the amount of which will most likely exceed the price of the replacements from the maker of the car.

That a repairman will be able to produce parts which will be better than those to be had from the maker, is scarcely to be believed. The repairman works under the greatest possible disadvantages; he is not in a position to select intelligently the materials, and he is without the working drawings from which the arts were originally made, so that "rule of thumb" and methods involving surmise will represent the boundaries of such efforts.

SOME PERPLEXING PROBLEMS CONFRONTED THE REPAIRMAN

In this particular undertaking, there were some perplexing problems to be solved, among which the overhauling and timing of the valves will be mentioned. The valves were in excellent order, but owing to repeated grinding, the seats were very wide, and it was believed that it would be difficult to maintain them tight against leakage. It was decided therefore, to bore out the passageways sufficiently to reduce the face of the valve seat, with a view to inducing a better condition.

The valve stems battered the ends of the tappet rods so much that timing was quite impossible of realization, and the cams were worn so that in the absence of any adjustment, provided by the maker, it was decided to do one of three things as follows:

(a) Purchase new camshafts, lifts and valves.

(b) Improvise a means of adjustment on the lifts.

(c) Purchase new valves with stems long enough to make up for the difference.

In a further examination of the system, and considering the work which would have to be put upon the valve seats to render them fit, it was decided that the adjustment difference could be made up by grinding the valves on their seats, so that the stems would extend down towards the lifts, a part of the total distance to be made up, and it was further decided that the valve seats could be machined down for the rest. In this way the repair undertaking was completed satisfactorily and without the purchase of any new material at all, and it is believed that the timing will be quite in keeping with the best expectation, considering the ability of the car in the first place.

HALFTIME GEARS RENDERED EXCELLENT SERVICE

Referring to Fig. 2 it will be observed that the halftime gears were of the shrouded fiber type, meshing with a steel pinion. The fiber lasted for a considerable time, but in the long run it rotted out and the teeth broke off as shown at T1, T2 and T3 in one case, and T5 on the other gear. The shrouds S1 were of phosphor bronze, and were riveted into secure relation after the pressure was put on in the process of manufacture. The fiber gears were built up onto a spider S2, and were keyed onto the shaft by means of regular key stock as shown in key K1.

The pinion was keyed on its shaft, and the key K2 was rather loosely fitted, with a considerable radial appearance, which may be noted in the illustration. The teeth of the pinion T4 were badly ground, and were therefore much deformed, which grinding process is due to rubbing contact with the fiber of the halftime gears. It is a well understood fact that fiber has this grindstone property, and in the machining process, because of it, the tools are dulled very quickly.

Fiber is used in halftime gears because it is not a noise producer, although the grinding process, as above mentioned, is likely to produce a perceptible hum or grating noise. If it is desired to get away from whatever ills there are attached to the use of fiber, it will be necessary to "lead" steel gears, in order to cause them to perform without noise. In the leading process the flange under the teeth is cut back to form a recess, and Babbitt metal is poured in all around the inner periphery, after which it is machined down to a uniform thickness. This process eliminates noise, under the conditions named, and the ability of steel gears may then be taken advantage of. The steel, if it is rendered extremely hard by heat treatment, will be more likely to produce noise than if it is left in the normal state. Following out the same line of reasoning, cast gray iron halftime gears, properly cut, will make less noise than steel gears. Bronze, on the other hand, has excellent "bell" properties which are extremely difficult to deaden.

In dissembling the motor, it is necessary to "spot" the meshing gear teeth, in order that the same teeth will be reengaged during assembling; otherwise the timing of the valves will be thrown out, and the motor will have to be retimed, which, to a novice, may not be an easy problem to solve. Even with skilled men it is better to spot the gears, so that they may be quickly replaced, thus saving the necessity of going over the timing, and this foresight will react in favor of a lower cost of the undertaking.

CHASSIS SIDE BARS PROVED TOO LIGHT FOR SERVICE

The best indication of the lack of suitable strength of the chassis frame is presented in Fig. 4. The frame broke at a point about 5 inches back of the rear arm forming the motor support, and in line with the center of the flywheel, thus showing that the work transmitted to the side member at a point opposite the flywheel was greatly in excess of the ability of the side member to sustain. Cross-bracing was depended upon entirely through the motor frame, and the nearest lateral back of the motor arm was found to be far enough away to be of no value in restraining the twisting movements induced by the motor in service.

The motor vibrates considerably at the higher speeds, and a close examination of the same would lead to the conclusion that the clutch, which is a weighted contracting band type, is not in good kinetic balance. No doubt the clutch was statically well balanced, but the considerable vibration set up in the motor at

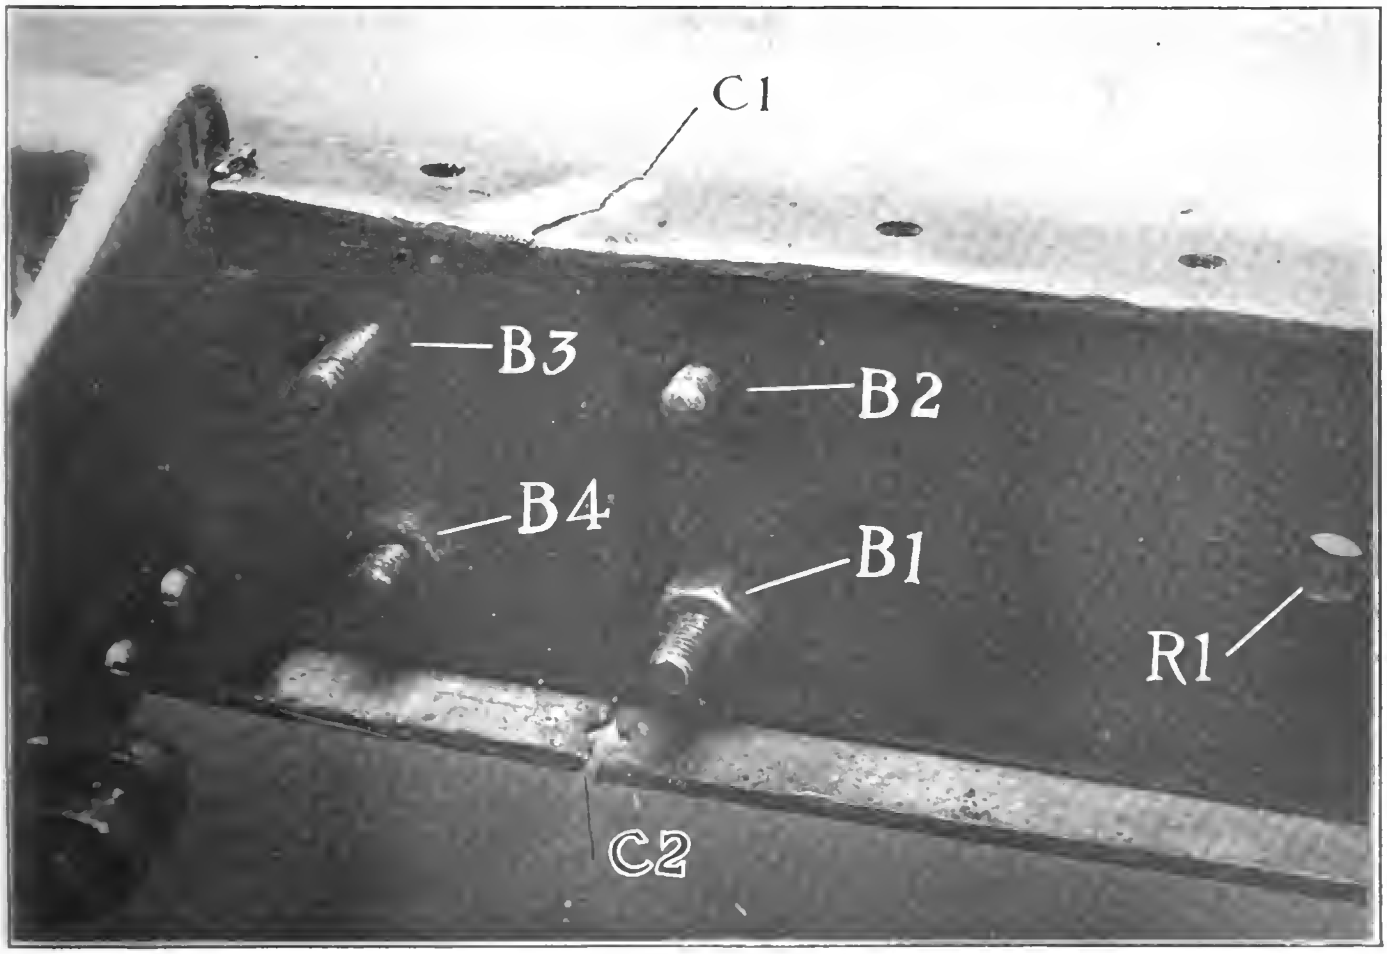

Fig. 4—Broken side bar showing evidence of lack of strength and the repair plate bolted and ready to rivet into place

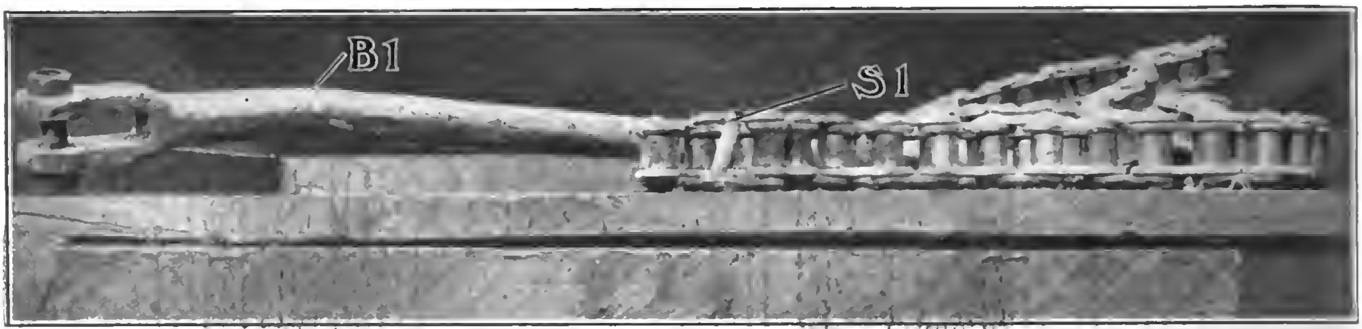

Fig. 5—Presenting the bent radius rod showing lack of due strength, and the sprocket chain with evidences of much wear

the higher speeds cannot be accounted for in any other way than that due to the absence of kinetic balance which is an impossible condition in practice, if a counterweight is employed, provided the same lacks in symmetry, comparing it with the mass which has to be counterpoised. Referring again to the figure, the fracture C1, is irregular, and in the plane slightly out of the vertical, which will be noted by observing the location of the fracture C2 at the bottom flange. The trouble started at a bolt hole in the bottom flange, and a further examination of the metal indicates a crystalline condition, which might have been due to vibration, although it is possible that the metal employed was of a basic character, rather high in the metalloids.

In the repair of this chassis frame a plate, substantially a quarter of an inch thick, without flanging, was laid up against the webb on the inside and riveted to the side bar. One of the rivet holes, R1, is shown in the neutral metal, and this is obviously a valueless situation. The rivets should be placed at points near the top and bottom flanging, in order that they might support the repair plate in its relation to the damaged side bar, in the zones of extreme fiber strain. The bolts B1, B2, B3 and B4 are placed on the two sides of the fracture, and bolts are employed in this location in order that they may be utilized in attaching other members of the car makeup to the frame. Riveting is better, and hot riveting is better than cold, because as the rivets cool off they will draw the plate tightly against the broken side frame, thus making them more efficient.

DISTANCE ROD NOT PROPERLY PROPORTIONED

These members, considering them structurally, belong to the two pin strut family, and, unfortunately, the work comes on diagonally, and the amount of the loading varies over the broadest ranges. Fig. 5 shows that this rod was round in section, and that it deformed at B1. Since the rod was of uniform section it is reasonable to suppose that the point at which deformation took place is that of greatest concentration of the load, and one way to maintain the minimum of weight would be to make the section greatest at the point of greatest strain, and taper off in both directions therefrom. The formula used for proportioning struts and columns, while it is of excellent value, is nevertheless involved in uncertainty, and a practical example such as this offers many advantages to the car builder, and shows the repair man what to do if he wishes to make a permanent repair.

The same illustration presents one of the sprocket chains, and the rivet S1, which is attached to the repair link, is loose in the link hole, which is an undesirable condition, but it is the method by which it is possible to prove that riveting should be very properly done throughout chains, in order that the life thereof will be long and satisfactory. A further examination of the chain will tell that the rollers were considerably worn, and this is an indication of the fact that the sprocket teeth are much deformed, due to wear, so that a severe wedging action takes place every time each link settles into the sprocket teeth.

In making a repair it is a common practice to absolutely disregard the condition of the sprockets, and to attempt to apply new chains to them. The result is bound to be costly and unsatisfactory, because the new chains will be destroyed, due to the wedging action of the worn teeth of the sprockets, and it will be the heighth of economy to place new sprockets on the car with the new chains, thus bringing this important portion of the automobile up to its original high standard, and in this way reduce the greatest noise producer to a condition of substantial silence.

PISTONS AND RINGS SHOW CONSIDERABLE DEPRECIATION

The four pistons as they were taken from the motor were grouped as shown in Fig. 7 and enlarged in order to bring out the information desired in relation to depreciation. Each piston has five rings with overlapping joints with parallel faces, and the greatest trouble seems to be due to fracture of the metal of the rings at the joints. R1 shows a joint with one of the overlapping projections broken off, and a very small portion of the face still in contact with the uninjured extension of the joint. R2 presents an accentuated case with the same character of fracture. R3 is different in that the ring broke off at a point in the full section back of the joint. R4 shows a ring with both ends broken back of the joint, and the other rings on the same piston are in practically the same shape. There are two serious phases to this character of trouble; the broken joints suggest that the disjointed portions of the metal will remain in the groove, for a time at any rate, and it will be a most fortunate circumstance if they do not score the surfaces of the bore of the cylinder and do other damage besides.

The rings, in addition to showing that they were rendered "rotten" in service, lost their temper and slunk away into the grooves, so that they were incapable of rendering the service for which they were originally placed. The compression must have been very poor in these cylinders for a considerable time before the motor was dissembled, and this is an excellent illustration of the futility of running a motor after the compression falls down, and not only on account of the poor service it will render, but in view of the damage which will be done by the disjointed

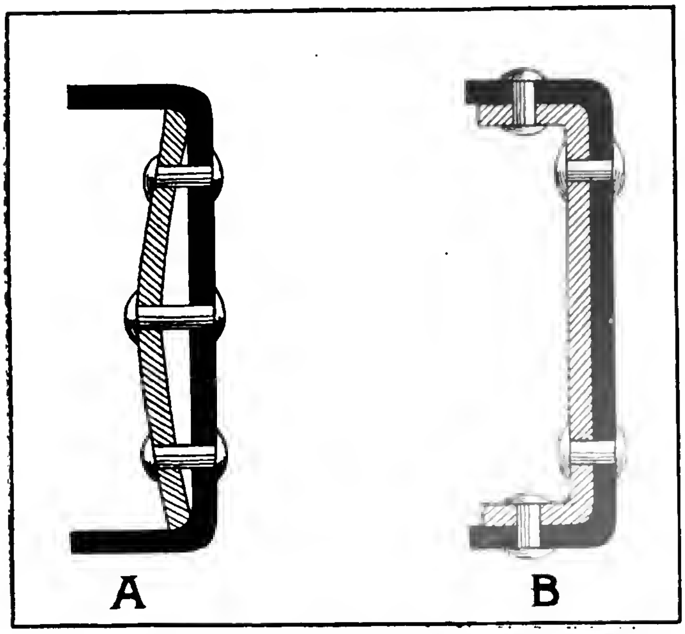

Fig. 6—Two methods of reinforcing side frames: A depicts the one selected; B portrays the more substantial way

portions of broken rings. The right procedure is to ascertain why the compression falls below a reasonable standard, and it is always necessary to dissemble the motor sufficiently to permit the inspection to be made with certainty. The pistons should be removed from the cylinders, the rings should be carefully inspected, foreign substances scraped off, and the rings should be examined to see if they float freely in the grooves. They should also be observed with a view to showing that they are of the right diameter to serve as packing rings, and if they prove to be too limber and do not press firmly against the cylinder walls with a certain uniformity all around the diameter, nothing remains but to resort to one of two choices as follows:

(A) Purchase a new set of rings of the right dimensions and insert them in the grooves to replace the inefficient rings.

(B) Remove the rings from the grooves in the pistons, and pein them out to a new uniform diameter, which should be slightly greater than the bores of the respective cylinders.

Laying the Foundation of the

BY THOS. J. FAY

INDUSTRIAL success, if the modern tendency portrays the right idea, is based upon the concentration of effort. In defining concentration care must be exercised in order to discriminate between the character of the undertakings which will result in a healthy expansion and the shrinking process which is bound to result when attempts at combining individual plant efforts result in a diminished output. The master mind must control the movements of the helm, steer clear of snags in the course ahead, and judge properly the license which it is safe to take in every emergency.

There are divers reasons why a series of manufacturing plants, located at different industrial centers, but under one management, will go a long way toward solving intricate problems. In individual, independent plants it is extremely difficult to induce a condition of "give and take." The lack of flexibility is prone to inequalities of the effort, resulting in a rush condition during a part of the year and idleness for a time. The skilled labor is barely brought to a condition of "good teaming" when the work runs out, and the effort at harmony of organization is dissipated when the workmen depart from the plant and search for new fields to conquer.

In the association of a series of plants, if each one is devoted to the manufacture of a separate character of the automobile, the respective plants will be free to produce the wares for which they are best designed, but they will be in a position to co-operate, because their respective idle periods will not synchronize with each other; when one plant is suffering from lack of regular work, the other will be in a state of congestion. There being a certain similarity of the machinery equipment used in the several plants, there is nothing to prevent the interchange of work.

Some time prior to June 21, 1904, J. D. Maxwell, of the Maxwell-Briscoe Motor Company, completed the first design of what is now well known as the Maxwell car, and Benjamin Briscoe undertook the organization of the Maxwell-Briscoe Motor Company, the preliminaries of which were completed on the above date. What is now known as plant No. 1, at Tarrytown, was acquired on October 1 of the same year, and 250 workmen were organized into a compact force and directed in the production of Maxwell cars.

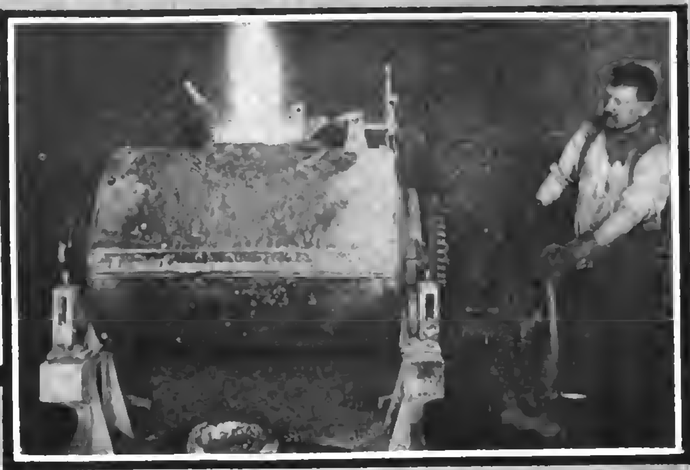
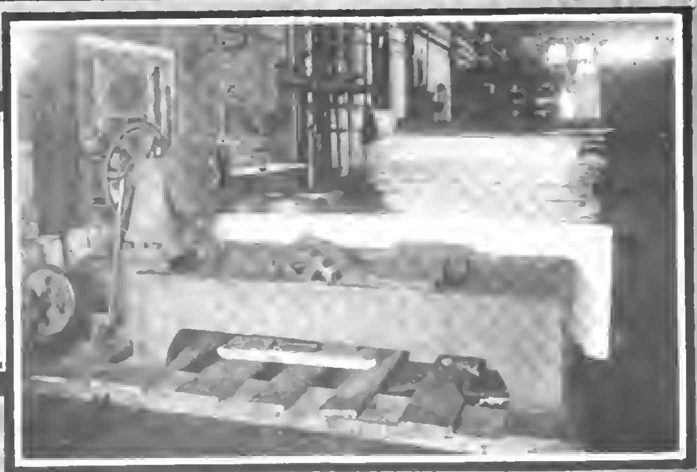
P—Instrument of precision. In this example the crankshafts are measured for accuracy; pins must be round and true to pass—an error of 0.0015 inch will be noted on the extensometer

Many Enormous Presses Turn Out Great Quantities of Pressed Steel



Rotary Furnace About to Discharge Molten Metal

One Day's Foundry Output of Aluminum Crank-cases.



New Rotary Field Testing Machine for Torsion Tests.

Ten cars were produced during the first year, and the progress made from that day to this will best be appreciated by observing the growing output, as follows:

MAXWELL-BRISCOE PRODUCTION FROM 1904 TO DATE

Year	Automobiles Shipped
1904	10
1905	823
1907	3,785
1908	4,455
1909	9,460
1910 to March 31	4,677
1910 for balance of year (estimated)	18,000

Note.—The estimate of the balance of the cars which it is expected will be produced before the end of this year is reflected in the present rate of production, which figures out 2,300 automobiles per month.

Prior to the merger which was at the bottom of the organization of the United States Motor Company, the Maxwell-Briscoe organization advanced to the point where the plants, as follows, were put into substantially full swing.

PLANTS DEVOTED TO MANUFACTURE OF MAXWELL AUTOMOBILES

Location of Plant	Square Feet of Floor Space
Tarrytown (plant No. 1)	149,000
Tarrytown (plant No. 2)	160,000
Providence (Rhode Island)	125,000
New Castle (Indiana)	507,000
Total	941,000

After the formation of the United States Motor Company, the Columbia plant, at Hartford, was taken over, and in this way the floor space, as above set down, was augmented by 350,000 square feet.

DIVERSIFIED MECHANICAL EQUIPMENT

Not considering the Columbia plant for the present, it will be the purpose to indicate in a general way a few of the Briscoe ideas as they are actually carried out at the Maxwell-Briscoe plants under the direction of J. D. Maxwell. It is estimated that the workmen in the Tarrytown plant have substantially $100,000 worth of material undergoing operations at any moment in the day. The illustrations, with their explanatory captions, are but a few of the many which adequately indicate the advanced nature of the work and the wide variety of special machine tools employed in the process.

It would be difficult to describe the process as it is controlled by the system employed, without following it out step by step, at a considerable expense of time, study and space, but it will be possible to indicate in a general way the primal objects. To begin with, time and experience have adequately shown that a manufacturing concern, if the work is to be done with certainty on a large scale, must be on a self-contained basis. To answer this requirement plant No. 2, at Tarrytown, is fitted out with every possible facility, from the enormous presses which form the side bars, cross-members, brake drums and other parts of pressed steel, including pneumatic riveting machines, revolving jigs, and a diversity of miscellaneous equipment, to the forming system and facilities by means of which the metal bodies are quickly and accurately produced.

As an intermediate detail, the side bars, cross-members and small parts which go to make the chassis frame complete are dipped in an anti-rust solution and kept therein submerged until the material smears over and penetrates into every little crevice all over the surfaces, and this solution thus quickly applied also serves as the priming coat over which the finish is ultimately applied. In this relatively small detail will be found an illustration of the very method by which quality and a high rate of production are made to survive in unison.

In the same plant the foundry building occupies an extremely important level. It is a well-lighted structure, commodious in size, and the tilting furnaces, with oil burners, are of the most modern make, with a sufficiently numerous battery to turn out all the castings required, in view of the fact that pressed steel and drop forgings take precedence over other forms of material at every possible point in the makeup of the automobiles. The foundry has a considerable undertaking in turning out the castings as used in the carbureters, and in thus manufacturing its own carbureters, starting with the "pig" and ending in the nearby plant with its quota of automatic tools, the company presents the same absolute front that it does all along the line.

A famine of material, or the congested condition of parts makers, can have no bearing on the operations of this company; its sole outside source of trouble is centered in the purchase of raw material and this policy is carried to such a limit that Maxwell-Briscoe patrons are offered the advantages which come from a manufactured stock of repair parts, to whatever extent they may be in reasonable demand. A building in plant No. 2 is devoted exclusively to the systematic and proper storage of a reasonable number of the parts which go into cars of this make, and a system of accounting which has been worked out to a successful issue permits the parts storekeeper to quickly and accurately fill such orders for repair parts as may come in from time to time. The reserve building in which these repair parts are stored is fireproof, and was erected at quite a considerable distance from the surrounding buildings. From time to time the machine tools, if they run out of shop order work, are permitted to fill in on live repair parts, with the understanding that even if they are not used in repair work, they will ultimately find a place in regular cars, but in order to be able to do work of this character on a stock basis it has been necessary to standardize the automobiles and the component parts thereof, so that the risk of ultimately acmulating stale stock would be minimized.

STANDARDIZATION PROBLEM SOLVED

In a large undertaking such as this it was one of the original Briscoe ideas to so cope with the problems of standardization that it would be safe to prepare for the quick and accurate production of parts on a large scale. In order to thus proceed it was necessary to definitely establish the exact design of all the parts, and then make jigs, tools, and fixtures which, together with special machine tools, would eliminate the personal equation and permit workmen to specialize for the best result. The enormous cost of the special tools, jigs, fixtures, etc., which were found to be necessary in this venture is the best guarantee anyone can have that immature designs would have been fatal to the project, and the growth and expansion of this industry lends a substance to the belief that forethought governed the divers acts which led to the methods of manufacture in vogue.

ARTISANS SPECIALIZE ON PRODUCTION

The old idea among machinists was that it took seven years to learn the trade, and that every workman should be capable of doing every possible operation involved in machining processes. The time was when "one-man power" obtained in manufacturing establishments, and each workman was called upon to know how to do every operation, thus making it possible for one man to direct everything. In these days, especially with plants in almost every industrial center in the country, the aggregate output of all combined, reaching into almost unreadable figures, the one-man power is centered in the great organizer, in this case Benjamin Briscoe, who depends upon a corps of trained executives, and they in turn place reliance upon an equally essential corps of departmental heads, who in turn engage the workmen and employ them in the capacity of specialists, so that the work is done day after day, and oftentimes year after year, in such a way that one man learns how to do some one thing, with never a thought or reason for wanting to do anything else.

The work is so grouped in the several plants that it transverses in the direction of the finished product from the source of supply as it is represented by raw material, and while inspection facilities are utilized as a checker against errors at important points in the process, the fact remains that errors do not accumulate because through the methods worked out a mistake cannot get beyond the man who makes it further than to the man who performs the succeeding operation.

Crankshafts will serve as an illustration of the automatic method of discovering errors. After they are cut off, centered, the cheeks milled and the pins ground, they go to the inspection department, and are there centered in a testing machine which will develop any variation in excess of 0.0015 of an inch of a pin out of round. Notwithstanding the accuracy of this test, the crankshafts go to a run-in machine, where they are mounted in place, the bearings clamped down, and the shafts are given a run-in test for a sufficient time to ascertain as to their respective qualities.

Cylinders, after they are roughed, ground and tested for tightness, are set up in a fixture and placed upon the platen of a multiple spindle machine where they are completed in three separate operations by as many men. The work is done progressively, and should one of the men fail to perform with the exactness which is demanded, the next man in picking up the work would be likely to discover the discrepancy, but should he be so blind as to overlook a fault, the error will be for discovery by the third man in the series. The point uppermost in this progressive shop system is that no man completes a job.

The component parts of the power plants, after they pass through the progressive method of manufacture, go to the assembling department, and, there, placed upon a "block" and the crankshaft is mounted into place; thereafter the clutch, flywheel and relating members are inserted, and if the rotating parts are free, and apparently in the right relation, the workman who performs this part of the work passes it along to the next man, who puts a belt over the flywheel, and from power, which is available, gives the assembly, in this incomplete state, a run-in test. After a sufficient time, if all goes well, the incomplete power plant is passed on to the workmen who apply the cylinders, insert the valves, and do such other work as may be necessary to advance the motors to a near state of completion. The substantially completed motors are then given a preliminary run-in test, and if they prove to be sufficiently promising they are then forwarded to the regular testing department, where, by means of calibrated fans, they are given their rated load and run for a sufficient time to assure that they will be in fettle to make it worth while to mount them into the chassis, there to receive tuning-up treatment, to be followed by a road test.

Columbia Plant Was Merged

FACILITIES, far beyond the present and prospective future output of the Columbia Motor Car Company, at Hartford, Conn., formerly the Electric Vehicle Company, and now a component part of the United States Motor Company, are afforded by the factory as it stands to-day, both as to space, equipment, system of handling materials, and men.

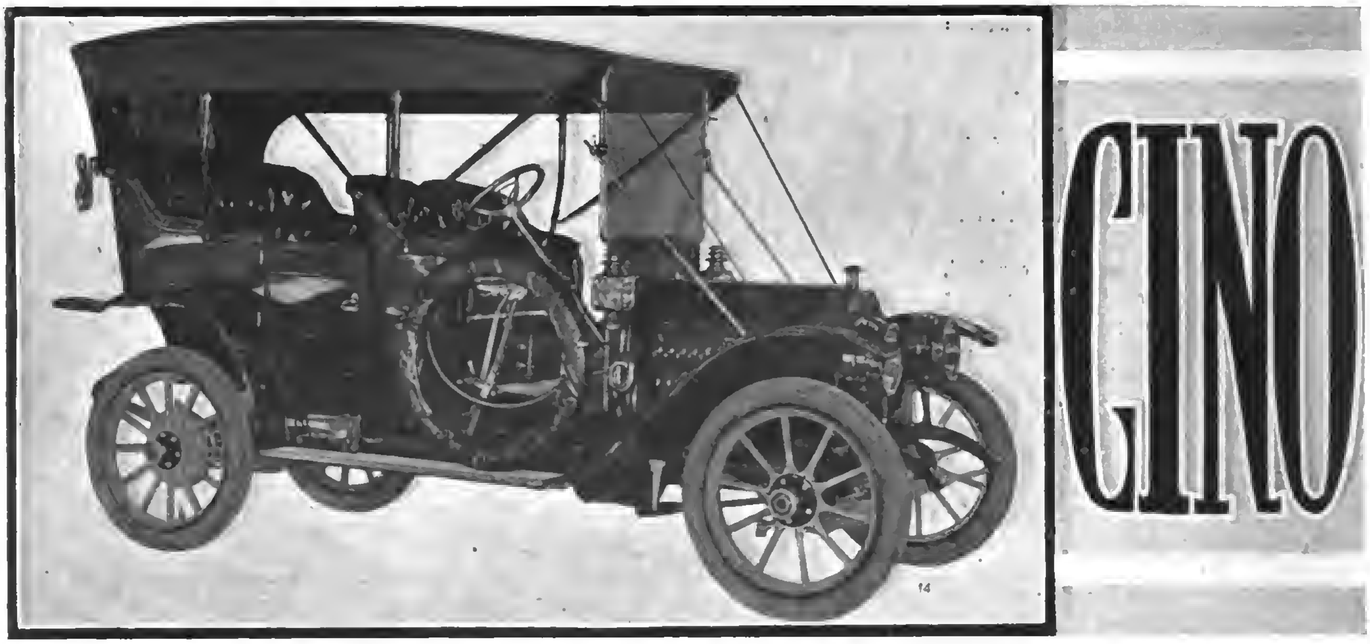
Part of Forging Equipment, Which is Unusually Complete.

Stock of Crankcases Finished and Waiting for Assembly.

Row of Tested Cars Awaiting Painting and Body



As a Touring Car the Cino, from Cincinnati, Displays a Number of Attractive and Meritorious Features

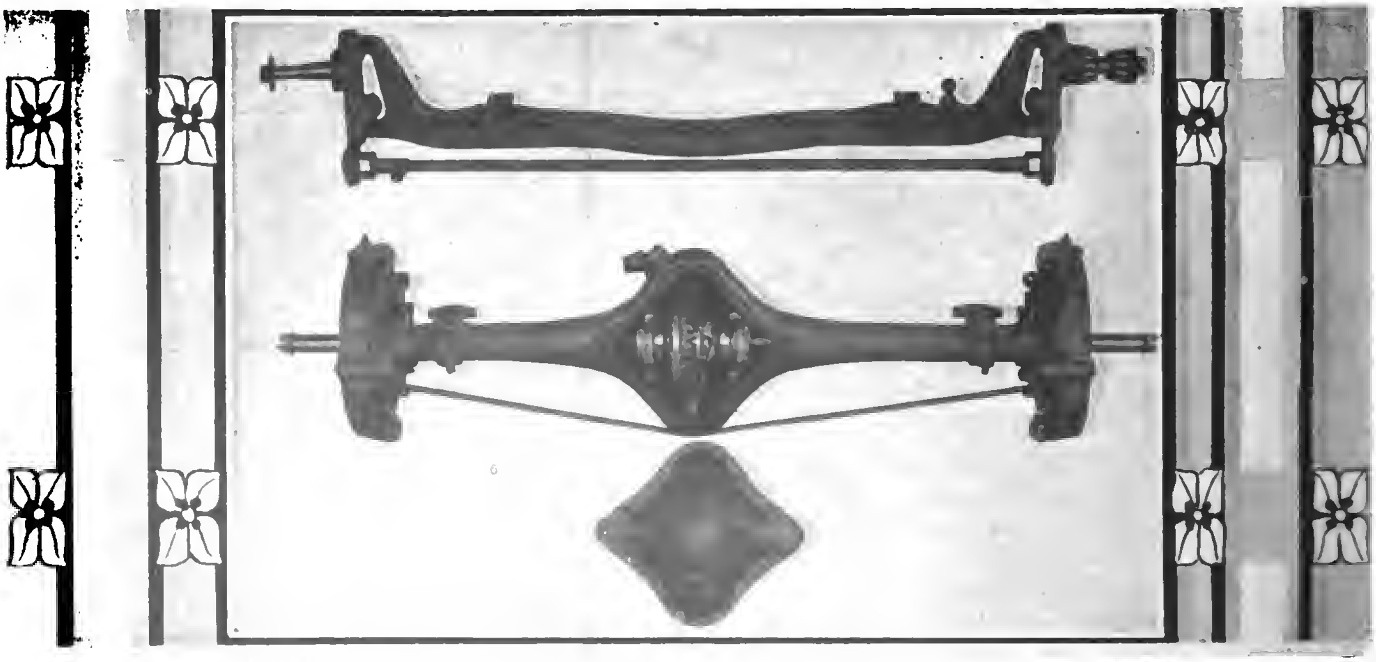
Haberer & Company, Offices and Factory at Cincinnati, O.

Motor, four cylinder, 4 3-8 by 5 inches; cylinders cast in pairs, with all valves in the head.
Crankshaft drop-forged and heat-treated; three bearings of Parson's white brass.
Ignition by Remy magneto, with dry cells as auxiliary.
Carbureter, Stromberg.
Lubrication by three-feed pump, maintaining a constant level in the crankcase.
Vertical tube radiator radiator with six-bladed belt-driven fan and centrifugal pump.
Multiple-disc clutch; 25 steel discs and nine springs, located in change-gear case.
Three-speed selective change-gear, carried on subframe.
Drive through shaft with two Spicer universal joints.
Rear axle full floating, with pressed steel housing; Timken roller bearings.
Internal and external brakes on rear hubs, former the emergency and latter the foot brake; bands faced with Thermoid.
Front axle made by Timken; weldless drop-forging, I-section.
Worm-and-sector steering gear with 18-inch hand wheel.
Wheels 34 inches in diameter, 10 spokes front and 12 rear; 34 by 4-inch Diamond tires standard.
Front springs semi-elliptic, 36 inches long; rear springs three-quarters elliptic, 46 inches long.
Pressed steel frame with four cross-members and subframe.
Wheelbase 113 inches; weight about 2,550 pounds; price with touring body, $2,250, including five lamps and gas generator.

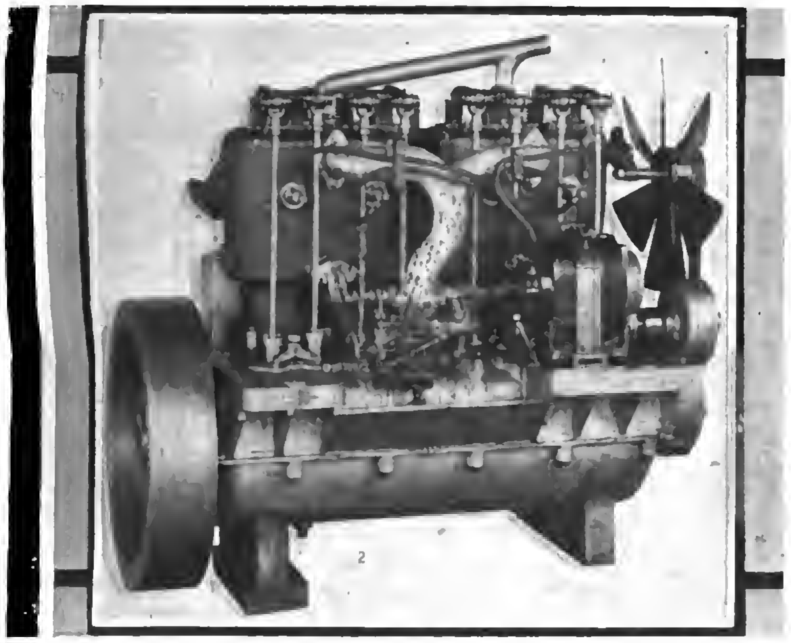
CINCINNATI'S reputation as a manufacturing city, especially in the line of machine tools, at least equals that of any other city in the country. Until quite recently, however, the Queen City's part in the automobile industry has been only to make the tools with which other cities made the cars. For the 1910 season an even half-dozen makes of automobiles will bear the Cincinnati impress, and of these one of the most important is the Cino, the product of Haberer & Company.

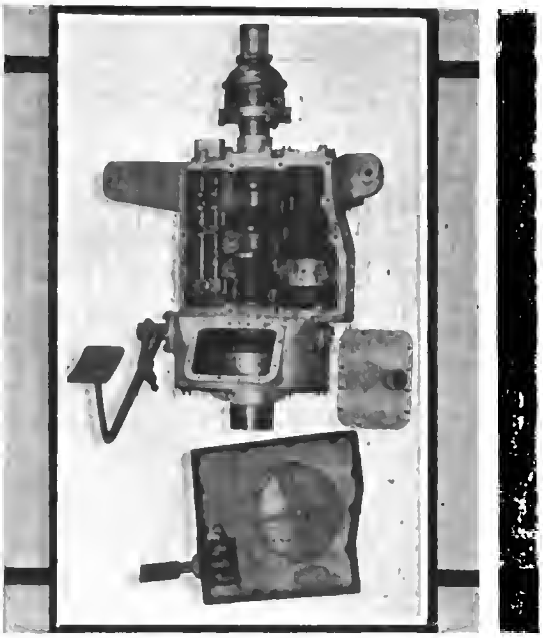
In most respects this car follows conventional lines of design. The motor, rated at 40-horsepower, the multiple-disc clutch and the three-speed selective change gear are made in Haberer & Company's factory on the designs of the company's engineer. The axles are of Timken construction, of well-known excellence.

Four cylinders, 4 3-8 by 5 inches, cast in pairs, and a three-bearing drop-forged crankshaft form the basis of the motor design. All valves are in the cylinder heads, in a single row, and



Cino Axles Afford the Solidity Necessary to Support a 2,500-pound Car with Its Full Passenger Load





Motor and Change-Gear Are Both Products of the Haberer Factory; the Latter Includes the Clutch

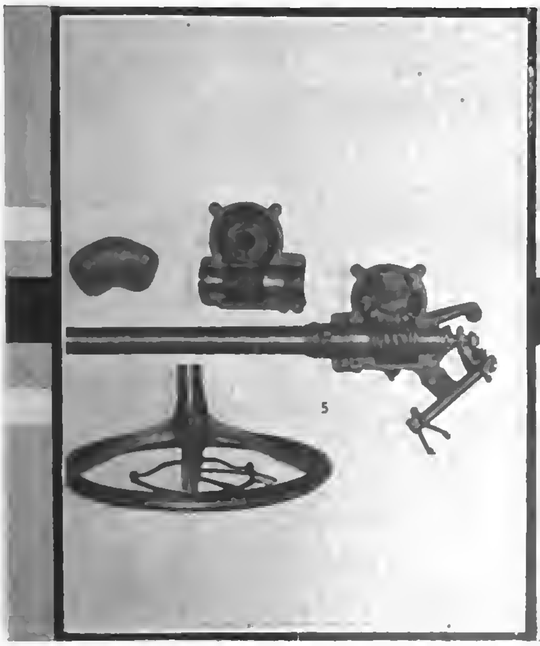
are actuated through rockers and push-rods from a camshaft enclosed in the crankcase on the right-hand side of the motor. They are unusually large in size, with heads of nickel steel, and vanadium steel springs, the latter being subjected to a treatment which gives them long life. The valves and their cages are easily removable for cleaning and grinding. The camshaft is a drop-forging with cams integral, and cams, push-rods and rollers are all hardened and ground.

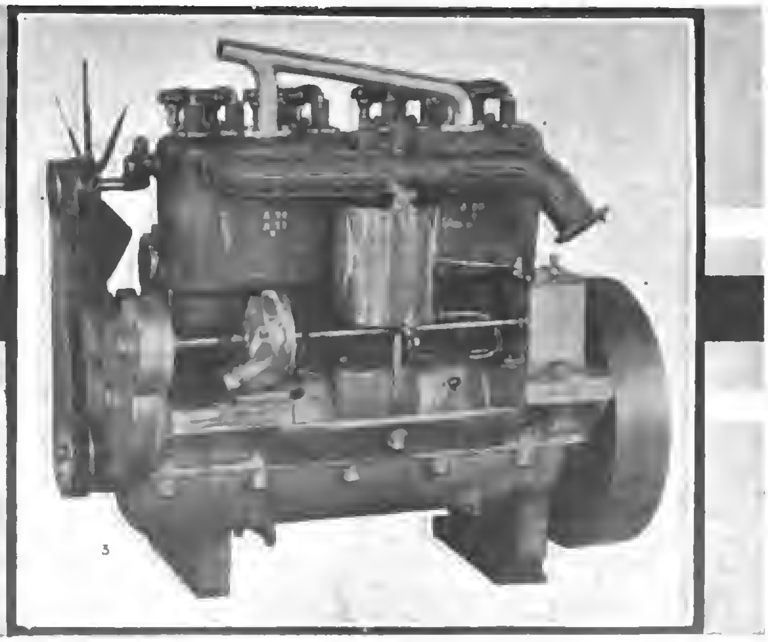
The crankshaft is a drop-forging, of liberal size, heat-treated for toughness and strength, and journals are ground to size. Die-casting of the bearings, of Parson's white brass, insures an even texture and wearing qualities. Castings of an aluminum alloy form the two halves of the crankcase, which has integral four arms by which the motor is supported on the subframe.

The arrangement of the motor accessories shows careful thought. The inlet piping is carried over to the right side, and with it, of course, the carbureter. The magneto is also located on this side, at the extreme front of the motor. The exhaust manifold is on the left side, and with it the water and oil pumps. These are on a common shaft, which passes through the pump and extends to the oiler mounted on the rear lug of the crankcase. Oil is carried in a large cylindrical tank set in close between the cylinder pairs, and is fed from the pump through sight feeds on the dash leading to the crankcase and clutch. A constant level is maintained in the former, and the cylinders are kept lubricated by the splash.

Clutch and change-gear are united in a single case, with connection to the motor through an Oldham coupling of good size. The clutch has 25 all-steel discs, under the pressure of nine springs of the same vanadium steel used for the valve springs. The shafts and gears of the change-gear are of substantial design and run on plain bearings. The sliding-gear shaft has milled splines, a commendable feature. The lay shaft has one bearing between the constant-mesh gear and the second-speed gear, the former being overhung; this is believed to give a better distribution of the stresses. Drive is through a shaft with two Spicer joints, the angle of the joints not exceeding three degrees.

The rear axle is live and with floating shafts; the axle body is pressed steel, and the differential and bevel gears are carried in an easily removable cage.





Cylinders Cast in Pairs, with Overhead Valves, Distinguish the Motor; Steering through Worm Gear

Showing Tubular Axle with Connections Well Protected

Sales Agents, Meixell-Downing Company, Indianapolis. Made by Clark Motor Car Company, Shelbyville, Ind.

Motor, four-cylinder, 4 by 4 inches.
Cylinders cast separately.
All valves on the left side.
Crankshaft drop-forged with five plain bearings.
Ignition dual; Remy magneto with separate coil.
Dry batteries on same set of plugs.
Carbureter, Schebler.
Gasoline tank under front seat, gravity feed, capacity 14 gallons.
Constant level splash lubrication.
Cooling by vertical-tube radiator with pump and belt-driven fan.
Leather-faced cone clutch, 15 3-4 inches diameter, 2 1-2 inches face.
Drive by shaft enclosed in torsion tube.
Single universal joint.
Change-gear on the rear axle, selective type.
Three speeds forward and reverse.
Annular ball bearings in change-gear.
Semi-floating rear axle; bevel gear ratio 3 1-2 to 1.

AMONG the additions of the past season to the automobile plants in the vicinity of Indianapolis, and adding to the prestige of that city as a center of the automobile industry, is that of the Clark Motor Car Company, at Shelbyville. This company has put on the 1910 market two models, of 30 and 40 horsepower, and selling at $1,400 and $1,750, respectively, for which the Meixell-Downing Company, of Indianapolis, acts as general sales agent. The two models resemble each other in most essential features, but the present article will treat of the Clark "30" exclusively.

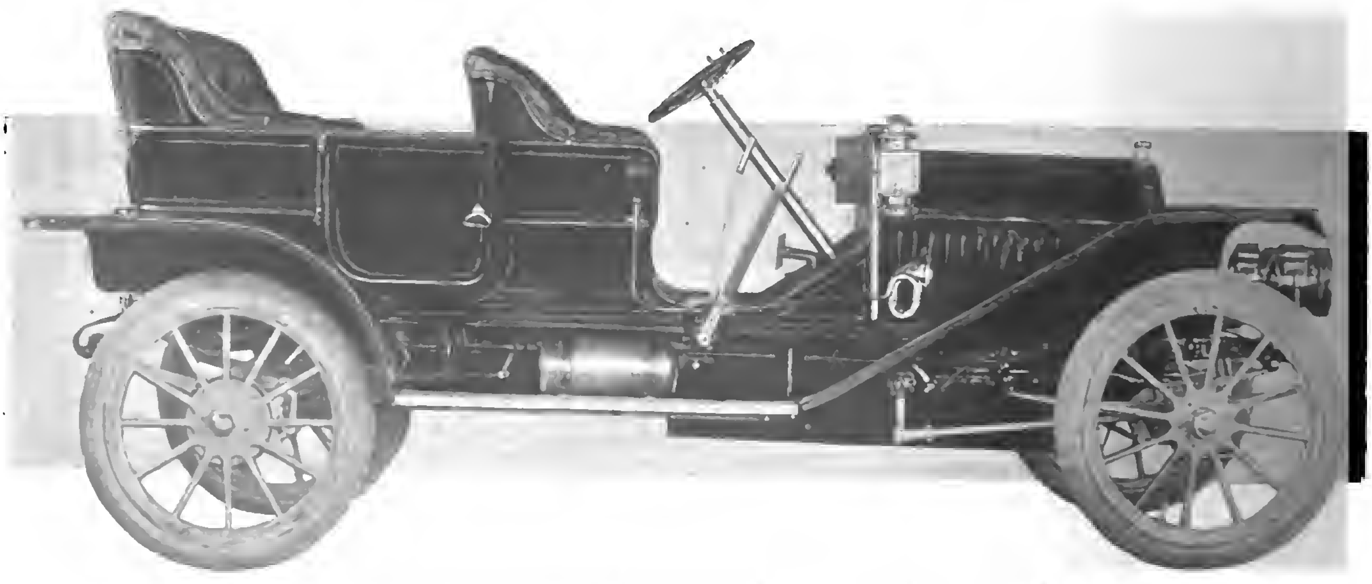
As in any form of engineering work, a substantial foundation is the first requisite of a successful automobile. The designer of the Clark seems to have given especial attention to the chassis of his car. The frame is of pressed steel of the conventional channel section, 1 1-2-inch flange, and 3 1-2 inches deep for the middle half of its length; it has three cross members, the front and middle ones carrying between them a subframe for the support of the motor. The comparatively long wheelbase—112 inches—allows a minimum of overhang, the frame extending but 6 inches back of the center of the rear axle.

Rear-seat passengers will appreciate not only the lack of excessive overhang, but also the policy which caused the rear end of the frame to be hung on full elliptic springs of the double-scroll type 40 inches long. The front springs, as usual, are semi-elliptic, and the leaves of both are 2 inches wide, a generous figure for a 2,000-pound car.

The semi-floating type rear axle carries the gear case, according to the fashion which is steadily gaining in popularity. The axle is built up of tubular sleeves and a central case for the bevels and differential; the live shafts are 1 1-4 inch in diameter, and run on annular ball and Hyatt roller bearings. The bevel gear ratio is 3 1-2 to 1, which is figured to give a maximum speed of 50 miles an hour. The change-gear gives three speeds forward and reverse, controlled selectively; the gears are a special grade steel, and the shafts run on annular ball-bearings throughout.

Torsional strains are taken up by a stout tube enclosing the drive shaft and bearing on its forward end a wide yoke, the arms of which are hinged to the subframe. Thus the drive shaft and its universal joint have only to transmit the power of the motor to the rear axle, instead of carrying these strains, as in some designs they are called upon to do. The clutch is a leather-faced cone, 15 3-4 inches in diameter and 2 1-2 inches face, and so arranged that its engagement is cushioned not only by springs under the leather, but also by the air entrapped between it and the flywheel.

For the motor recourse has been taken to one of the oldest and most reliable of the stock products, the Rutenber. The features of this motor are familiar to every automobilist. The one used in the Clark "30" has four cylinders 4 by 4 inches, cast separately, of course, and with a five-bearing crankshaft. One of the more recent details is the provision of a vertical shaft at the front of the motor, driven from the crankshaft by skew gears, which carries the timer on its upper and the oil pump on its lower end, and drives the magneto through another pair of skew gears. The magneto is a Remy, three-magnet type, and dry batteries are provided for starting.



Clark "30" Has a Well-Balanced Appearance, Due to Location of Body and Hood on a Long Wheelbase

Live shaft 1 1-4-inch diameter; annular ball and Hyatt roller bearings.
Internal and external brakes on rear hubs.
Foot brake external, emergency brake internal and equalized.
Brake bands faced with Raybestos.
Front axle tubular ball bearing.
Steering gear, worm-and-sector.
Hand wheel 16 inches diameter.
Wheels 34 inches diameter, 12 spokes.
Standard tire equipment 34 by 3 1-2-inch Fisk.
Front springs semi-elliptic 38 by 2 inches, 5 leaves.
Rear springs full elliptic, double scroll, 40 by 2 inches, 6 leaves.
Pressed steel frame, channel section.
Greatest depth of frame, 3 1-2 inches, 1 1-2-inch flange.
Three cross members with subframe to carry motor.
Wheelbase, 112 inches.
Road clearance, 11 inches.
Weight, 2,050 pounds with full tanks.
Price with touring body, $1,400, including five lamps and gas tank.
Standard color, Russian blue.

Rear View Discloses a Substantial Axle and Springs

Control methods follow the accepted standard. Spark and throttle levers are mounted on top of the steering wheel, and an accelerator pedal is also provided. The worm-and-sector steering gear has a 16-inch wheel mounted on a brass column 1 7-8 inch diameter. The change-gear lever, working on an H-shaped quadrant, and the emergency brake lever are side by side; the latter pulls back to apply the brakes, and has a button release. The left foot pedal releases the clutch, and the right pedal applies the service brakes, in the accepted fashion. Both sets of brakes are on the rear hubs, the emergency set being the internal and the service the external one. The emergency brakes are equalized by a balancing bar introduced in the connections. The bands are lined with Raybestos, the wearing parts are protected from dirt, and the adjustments are readily accessible.

A good degree of noiselessness in operation has been secured by enclosing the moving parts which are responsible for most of the usual noise, and by providing a large muffler, of a capacity to take care of the exhaust gases without setting up undue back pressure. A cut-out, operated by a foot pedal, is provided for speeding.

Thorough provision is made for lubrication of all wearing parts. The motor has its own lubricating system built integral; a pump, driven by a vertical shaft at the front of the motor, as mentioned above, keeps a constant stream of oil flowing to the crankshaft bearings, and maintains a constant level in the four crank pits, from which the oil is splashed into the cylinders. The motor has a large filling cap on the right-hand side of the crankcase. All bearing points on the chassis are provided either with grease cups or with Winkley oilers. Oil holes are believed to be worse than useless for automobile service, as they only catch grit, which is then carried directly into the bearing surfaces. The gearcase is filled with oil, and the ... of the rear axle is packed with hard grease. ... but occasional attention.

A. A. A. GIVES OUT 1910 GLIDDEN TOUR RULES

RULES governing the 1910 National reliability tour of the American Automobile Association for the Glidden and Chicago trophies are as follows:

The seventh annual reliability tour for the Glidden trophy for touring cars and the Chicago trophy for runabouts and miniature tonneaus will start at Cincinnati on June 15, 1910, and end at Chicago June 29, 1910, including Louisville, Nashville, Memphis, Little Rock, Texarkana, Dallas, Fort Worth, Oklahoma City, Wichita, Topeka, Atchison, St. Joseph, Des Moines, Cedar Rapids, Davenport, Rock Island and Moline.

TROPHY AWARDS

The trophy in each class shall be awarded to the entrant whose car completes the contest with the least number of points to its debit. See general rule 526.

In case of a tied score for the Glidden trophy or for Chicago trophy, the trophy will not be awarded, but suitable medals will be issued to the cars so tied, certifying that they have qualified as winners, and their names shall be properly inscribed upon the respective trophies.

Cars completing the contest with 97 per cent. of the winning score shall be awarded Glidden certificates setting forth in detail the performance of the car on the road and its condition upon final examination. Rule 525.

CLASSIFICATIONS AND ELIGIBLE COMPETITORS

Each entrant shall be a member of the A. A. A. or of an affiliated club.

Stock cars only shall be eligible to compete and shall be divided into two classes according to body equipment: 1—Touring car class; 2—runabout class, including runabouts, miniature tonneaus, surreys and double or single rumbles. Rule 403.

Any stock touring car, a complete description of which has been filed by the manufacturer with the contest board of the American Automobile Association, at least 30 days prior to the date of the tour, as provided in rule 32, shall be eligible to compete for the Glidden trophy.

Any stock runabout, miniature tonneau, surrey, double or single rumble, a complete description of which has been filed by the manufacturer with the contest board of the American Automobile Association at least 30 days prior to the date of the tour, as provided in rule 32, shall be eligible to compete for the Chicago trophy.

CAR EQUIPMENT

404—Each competing car shall be delivered into the custody of the promoter's technical committee for official examination before the start of the contest, at the date required by the committee, which shall be specified upon the entry blank to determine if it is a stock car and regularly equipped.

405—Each car must carry at all times during the contest its catalogued equipment of lamps, tools, tire tools, body, fenders, sod pan, running boards, muffler and body parts; and, in addition, may or may not use windshield, top, extra tires, baggage rack, lamp bumpers and supplementary tonneau seats.

406—Special mud aprons may be used in front of the radiator or bonnet screens between the side members of the frame, same to be attached before the start of the contest in a manner satisfactory to the technical committee.

407—Rubber bumpers for springs and rebound straps may be used without penalization for trouble with them.

408—Tire-inflating tanks of any nature may be used.

409—Cars are not permitted to use searchlights unless same are part of regular equipment, but may affix two ordinary gas or electric lights with generator or gas tank.

410—Covers over coil boxes on the dash, or wherever located, not permitted unless regularly provided.

411—Leather or other covers over magnetos not permitted unless supplied regularly with stock cars. This applies to any other part of mechanism as well.

412—Screenings or shields of any construction around carbureter not permitted unless regularly fitted to stock cars.

413—The cotter-pinning, or lock-nutting of nuts or riveting of bolts or studs, other than is regularly done on stock cars at the factory, not permitted.

414—The use of special springs or spring windings not permitted.

415—Shock absorbers will not be permitted unless listed under regular, optional or special equipment.

PASSENGER LOAD

416—A touring car shall carry four or more persons.

A miniature tonneau, surrey, or runabout shall carry two or more persons.

Passenger load in all body types must average 125 pounds per person or a like amount in ballast.

RESPONSIBILITY OF ENTRANTS

1—Each entrant by his signature to the entry blank shall agree that he is familiar with the rules, that he will abide thereby and accept the official records, and authorize the American Automobile Association to publish them in such manner as it shall determine.

2—Each entrant shall hold the American Automobile Association harmless and indemnify it against all loss or damage resulting directly or indirectly from or growing out of the operation, management or control of the car entered by him.

3—The American Automobile Association shall not be responsible for any damage that may be done to any car, its passengers or contents during the tour, nor for the theft of any car or any of its accessories or contents, the same being at all times subsequent to such entry, and until the close of the tour, at the risk in all respects of persons entering same.

4—Each entrant or his official representative shall be responsible for the acts of passengers in his car.

5—Each competing car must be delivered into the custody of the committee before 9 o'clock on the morning of Monday, June 13, for official examination and to check the inventories of parts carried as hereinafter provided for.

6—Each entrant shall name an official representative for each of his entries, on or before June 1, 1910, failing which the driver of the car shall be considered the official representative. Rule 426.

7—The official representative of the entrant shall be subject to all rules and penalties prescribed for the entrant, and shall be considered as the entrant in fact. Rule 427.

ENTRIES

1—The time for receiving entries shall expire on June 1, 1910, at 12 o'clock midnight, at the office of S. M. Butler, chairman contest board, 437 Fifth avenue, New York. Each entry must be accompanied by the entrance fee. Rule 432.

2—Each entrant shall give all details asked for in the entry blank and such additional information as the contest committee may from time to time require.

3—The contest committee of the American Automobile Association reserves the right to refuse any entry.

4—Entries shall be numbered in the order of their receipt. Rule 428.

428—Upon making an entry, each entrant shall appoint one observer for each car entered. See Rule 465.

429—No more than three cars of any one make may be entered in either of the body equipment classes provided in Rule 403.

430—The entry fee will not be refunded in case a car fails to start or is disqualified during the contest, or in any case, unless the contest is for any reason abandoned.

433—Any attempt at fraud in the evasion of the stock car definition or status of the car on the part of an entrant shall disqualify the car, the driver and the entrant.

TOOLS

417—All tools for the car will be carried in a special tool bag furnished by the promoter, which shall be sealed and handed over to the observer, and the use of tools other than those carried in the bag is prohibited. The number of tools is not limited to the supply sold with the car. When tools are needed the driver or mechanic will obtain them from the observer, who will keep a strict account of the number of tools used and see that they are returned to him at completion of work. Tire tools may be carried in the regular tool compartment of the car, but must not be placed in the official tool bag.

INVENTORY OF PARTS

418—Each entrant shall furnish prior to the start an inventory of all parts carried in his car, and these shall be officially checked, sealed and a record made of same.

TIRES

419—Each entrant may carry as many tires, demountable rims and tire chains and the parts which secure them in place as desired, or purchase or obtain them en route without penalty.

TIRE REPAIRS

420—There shall be no penalty for tire repairs, provided the engine be kept running while the repairs are being made and no other work is done. The time consumed in making the repairs while the engine is running, shall be added to the day's running time.

420A—The rule applied to tire repairs also applies to removal repairs, also anti-skid.

LUBRICATION EQUIPMENT

423—No additional lubrication equipment, such as pumps for forcing oil direct into crank case, will be allowed, unless cars are regularly sold with such equipment.

THE ROUTE

434—The route shall be exactly marked by one or more of the following methods:

A—By throwing confetti on the right side of the road 100 yards before and 100 yards after any turn. On long stretches, without turns, occasional throwings, especially at points 100 yards after passing any corner where a turn has not been made.

B—By providing each contestant with a description of the route, giving explicit directions of all right and left turns and right and left forks, and with occasional references to some conspicuous object. Mileage distance shall be placed to the left of each of these points noted in the route descriptions.

C—By marking the course with arrows and disks, the arrows to be placed 100 yards before a turn and the disks 100 yards after a turn. Disks shall also be placed 100 yards after passing any corner where a turn has not been made.

PRELIMINARY INSPECTION

435—Contesting cars shall be given a preliminary inspection preceding the start of the contest. At this inspection one representative of the entrant will be present with the technical committee of the promoter. An inspection card showing the condition of wheels, springs, frame, front and rear axles, steering pivots, steering gear, body, motor, ignition parts, lubricating parts, cooling parts, carburetion parts, exhaust parts, clutch parts, transmission and control parts, brakes and brake-operating parts, etc., will be filled out and any noticeable points about each that might later occasion dispute, recorded. This card must be attested by the entrant's representative.

SEALS

436—Metal and wire seals will be affixed by the technical committee as follows:

Gasoline Cars—Bonnet, coil box, transmission case, differential case, mud pan or apron and parts of ignition not beneath bonnet or protected by bonnet seals, and any other parts at the option of the promoter's technical committee. Where motors are under the body of the car, the floor, seat and deck boards must be suitably sealed.

437—Steam Cars—Bonnet, mud pan or apron, pilot light, thermostat, flow motor regulator and parts of steam system not beneath the bonnet and not protected by bonnet seals, and any other parts at the option of the promoters' technical committee.

(Continued on page 691.)

THE CARBURETER, ITS ADJUSTMENT, AND THE NOVICE

By HERBERT L. TOWLE

WATER-JACKETING of carbureters is resorted to for the opposite reason which makes it desirable on the motor cylinders, that is, to replace the heat lost in vaporizing the fuel, a small stream of hot water being by-passed around them from the cooling system of the engine. Carbureters not so provided take a portion of their air from a heater, connected usually to the exhaust manifold. The proportion of hot air can be regulated to suit the season. It follows that in winter when starting from cold much of the gasoline spray is not evaporated, or if evaporated is not properly mixed with air, and, therefore, passes through the engine unburned. For this reason it is usually necessary in cold weather to increase temporarily the gasoline supply till the engine warms up. This is sometimes facilitated by putting one of the carbureter adjustments under the driver's control by connecting it to a lever on the back of the dashboard.

The same fact, i.e., that cold gasoline does not evaporate freely, explains the need of flooding the carbureter to start in cold weather. Sometimes it is even necessary to warm the carbureter by pouring hot water over it or wrapping it in hot wet cloths. A good modern carbureter requires little or no priming in warm weather, as the suction due to cranking is sufficient to draw gasoline from the spray nozzle. If, however, "priming" is necessary, the user must learn by trial about how much to prime for different conditions. If the engine is warm, none is required. If it has stood over night or longer, the carbureter can usually be flooded until gasoline drips from the overflow outlet provided for that purpose. Too much gasoline, however, is as bad as too little. A strong spark will help matters considerably. If the user has a magneto he may count on a very weak spark when cranking with the spark lever retarded. The common dual ignition provision, i.e., a magneto for regular service and a battery and outside coil for starting, is intended for just this condition.

Incidentally the reader is cautioned to make a practice of shutting the main gasoline valve after every run. Carbureter float valves are notoriously prone to leak. While the engine runs, the gasoline consumption takes care of the leakage, but over night the leakage may not only flood the carbureter so as to render starting difficult, but waste gasoline seriously as well. If the engine balks owing to flooding, shut the main gasoline valve and turn the crank vigorously several turns to pump out the saturated air; when the engine starts, turn on the gasoline. In extreme cases it may be well to open the float chamber drip cock and draw off some gasoline to lower the level. This, however, is seldom necessary except with puddle type carbureters, of which mention will be made in the next article.

New let us consider carbureter derangements and their symptoms. Of these the following are most common: Clogged gasoline pipe or passage, dirt in spray nozzle, water in gasoline, leaky float valve, loosening of threaded adjustment in float valve, gasoline-filled float, sticking air valve.

Occasionally the gasoline pipe or strainer will be clogged by fluff which comes through the pipe and lodges in or near the union connecting the pipe to the carbureter. The symptom is misfiring followed by total "dying" of the engine. If the stoppage is only partial, enough gasoline may get through to permit restarting, followed presently by the same performance. If gasoline does not flow freely when the float is depressed, first open the sediment plug. If gasoline comes out freely the trouble is higher up, possibly in the float valve orifice. If careful poking with a wire does not bring the obstruction down, take out the float valve and poke down from above. In some cases it may be necessary to disconnect and remove the carbureter to get at the obstruction. If the latter is lodged in the gasoline pipe or union, gasoline will escape, after opening the sediment plug, only till the float chamber is empty. Disconnect the union, and if still no gasoline comes, disconnect the pipe at the tank end after first closing the main valve next to the tank. If the pipe is clear the obstruction may be located in the main valve itself, or in the entrance to the pipe from the tank. Usually the latter can be reached and poked out either from inside the tank through the filler opening, or from beneath. Before embarking on the above hunt, be sure that the tank itself is not empty.

The symptoms of dirt in the spray nozzle are quite similar to the foregoing, except that gasoline issues freely at all points except from the nozzle when the float is depressed. A fine wire will locate the trouble, but the nozzle should be flushed clean.

Water in the gasoline will cause the motor to stop absolutely dead. Open the sediment plug and float chamber, drain plug, and see whether gasoline or water issues. Be sure that the water is thoroughly expelled from carbureter and pipe. If the gasoline is strained through a chamois skin or through several layers of cheesecloth, any water will be separated out.

The sign of a leaky float valve is dripping. Pressing the float valve shut does not stop the leakage; this will distinguish leakage from faulty adjustment. The remedy is to grind in the float valve with pumice stone, taking care to keep the stem central.

Occasionally the threaded adjustment of the float valve may work loose, allowing the needle portion of the valve to settle downward and shut off the gasoline, regardless of the position of that portion of the valve against which the float lever operates. The symptoms resemble those due to an obstructed gasoline pipe, except that gasoline flows freely from the drip cock.

A cork float is apt to absorb gasoline gradually, making it heavier, so that it fails to close the float valve when the normal gasoline level is reached. This results in leaking easily mistaken for that due to imperfect seating of the float valve, except that it is stopped at once by pressing the float valve against its seat. A temporary remedy is to readjust the float. For a permanent remedy the float must be taken out, baked to expel the gasoline, and given two coats of shellac. A hollow metal float sometimes receives an invisible puncture, which causes it to fill gradually with gasoline and act like a saturated cork float. By warming it the gasoline will be expelled as vapor. Plunging the cold float into warm water will cause bubbles to issue, showing the location of the leak. When dried out and cold the leak should be carefully soldered up, using no more solder than necessary in order not to increase the weight of the float.

Dirt may cause the auxiliary valve to stick—a point easily tested with the finger. The valve seat, if not of metal, may leak, causing a weak mixture at low speeds.

While on the subject of float valves it may be noted that there are five methods of controlling these valves, as follows:

1. By direct attachment of the needle to the float itself, so that closure is accomplished by the upward movement and pressure of the float.

2. By indirect action through a lever, which multiplies the pressure available to hold the valve shut.

3. The valve may be loaded, so that it shuts off the gasoline by its own weight. The float in that case operates to open the valve when the gasoline level falls, rather than to force it shut when the level rises. This device has the advantage over the preceding, that vibration of the float is not so likely to be communicated to the valve, and the latter is more likely to hold tight.

4. The valve may be closed by spring pressure instead of simply by its own weight. This makes it still more secure against opening from vibration. The float acts as a counterbalance as in case 3.

5. The valve may be weighted and spring tension added to steady it. This is perhaps the best system of all.

By noting which of the above devices is used in his own carbureter the reader will be able to judge whether leakage is due to imperfect seating of the valve or to a fault inherent in the valve's design.

DO WE SEE OURSELVES AS OTHERS SEE US?

By JAMES S. MADISON

WHEN the average motorist, like you and me, has returned from a trip of 100 miles, or one of greater or less distance, in talking it over with his friends or family, he devotes, consciously or unconsciously, a certain proportion of his remarks to the "other fellow."

It is clear that the other fellow does many things he ought not to do and leaves undone many things he ought to have done, and in the slightly modified words of the prayer-book, there is no health in him. Whether the proportion of the remarks devoted to this subject is large or small, depends upon the mental attitude of the speaker and upon the behavior of the other fellow.

It is undoubtedly true that many of us have ample cause for annoyance, just as there are many of us who are quick to take offense and quick to resent real or supposed violations of our rights. There are also many of us who are thoughtless and inconsiderate and who undoubtedly give cause to the non-motoring public for condemning automobiles and their drivers in general.

Judging from a somewhat extended acquaintance among motorists, I do not believe that as a class they are more selfish, or less courteous or considerate of others, than any other class of persons. But as in other cases, the whole membership suffers for the acts of a few. No sane person thinks of condemning the whole legal fraternity because he knows of a few unprincipled lawyers; or the whole medical profession because he is aware of the existence of incompetent doctors. There is equally good reason for not condemning the motoring world in its entirety, because of the acts of a small portion of it.

DUTY OF ALL MOTORISTS TO HELP

Each member of this world, every person who sits behind the steering wheel, no matter what his color or how humble his station, has it in his power to do a real kindness to many people —autoists and non-autoists—every time he goes out on the road. He has it in his power to increase or lessen the prejudice existing in many localities against the automobilist. Every time he drives through crowded streets, he has the opportunity of showing whether he is a thoroughbred or a scrub; of making friends or enemies.

If we could all decide before starting on a trip, that we would not only avoid injuring any animal, property or person, but that we would not interfere with any creature's rights, pleasure, or comfort, we would all be happier. Our cars would run more smoothly, more sweetly, for courtesy is the best lubricant on the market and the "other fellow" would soon disappear.

I have been impressed with the fact that motorists are often thoughtless when passing other cars, horse-drawn vehicles or pedestrians on a dusty road. If one is going along at any speed above 16 or 17 miles, he is leaving a dense cloud of dust behind him and if he meets another automobile coming from the opposite direction, he may feel absolutely sure that the occupants will get the full benefit of it. If he has any doubt about this, let him turn around the next time he passes anyone on a dusty road and see for himself. It may be that owing to the size of the tires, shape of the car's body, etc., his car may not raise much dust at the speed mentioned. If it does not, so much the better, but should he increase his speed to 20 or 25 miles, he will bring into existence a cloud of dust that will fill eyes, nostrils and lungs and cover entirely the person of any one unfortunate enough to encounter it.

PRACTICABILITY OF THE GOLDEN RULE

To the occupants of automobiles it is bad enough, although they are exposed to it only for a few moments, but to those of our fellows who are on foot, or are riding behind horses it must be maddening. By far the worst of it could be avoided by slowing down to a non-dust raising speed. Every driver ought to know at what speed his car raises dust. If he does not, he ought to find out the next time he encounters a dusty road. If he will make a few simple observations on his car's ability to raise dust, he will probably get a new conception of what a pest he may be under certain conditions.

I never feel like blaming the farmer, driving horses which are drawing a heavy load, for not showing any great enthusiasm or alacrity in turning out at the sharp honk of the horn. It may be that he has already turned out two or three times in a mile and if the distance is five miles to his home, probably he has been honked at ten or fifteen times. If the road is dusty and the day windless, he has been enveloped in ten or fifteen clouds of irritating dust. Is it any wonder, then, that when he reaches home he is in a belligerent frame of mind? My plea is that each of us should remember him and contribute as little as possible to his discomfort.

Personally, I think it is courteous and therefore good policy to give some sign of appreciation when passing the man who has turned out for me. A friendly nod, informal salute or a simple wave of the hand creates good feeling. While it is true that the law requires him to turn out, that is no reason for unwillingness to acknowledge the fact that he is obliging us at some inconvenience to himself.

Another factor in bringing us ill-will is the warning signal with which the cars are equipped. This is due to the kind of signal, our manner of using it, or both. In order to demonstrate that the signalling devices possess the property of rousing one's ire, let a car owner select any road much traveled by automobiles and run his car over it for several miles at a low speed. He will find that the metbods used by his brother motorists when they wish to pass him, vary widely.

VARYING MESSAGES OF THE HORNS

Some signal in loud peremptory tones; some will toot the horn a dozen times; some only once or twice. Some will seem to say: "Will you please turn out for me?" Others, "Turn out," while still others seem to say, "Get out." I favor a musical, deep-toned horn and I am sure that a much larger proportion of the public will heed it willingly and promptly than they would the rude demands of some other kinds of signals. Many of us use our horns too much. We could get the same results with greater satisfaction to all concerned, by a little more thought and a little less rapid driving. We should follow the example of the careful expert who uses his horn sparingly. Much tooting is the prerogative of the beginner or the fussy driver.

Have you ever seen a two-ton touring car with six or seven passengers driven by a big muscular chauffeur, bearing down a decrepit old man or woman or a frightened child, tooting his horn like a fiend? What do you think of it?

Some of us also use the muffler cut-out too frequently. It has of course, a legitimate use, but it should be employed only rarely. Many drivers will open the cut-out in preference to opening the throttle, not fully appreciating the fact that it is a device that produces a highly objectionable sound. We should all realize that the cut-out, so used, is a nuisance. In some instances the driver probably thinks it is an evidence of smart driving to cause his car to gain rapid headway by opening the muffler. It is much cleverer to attain the same result by an almost imperceptible touch of the throttle lever or accelerator, unless indeed the car begins to slow up on a hill and the driver wishes to avoid changing gears.

The responsibility of helping to remove the prejudice against automobilists and of doing something definite to render the highways of the country safe and comfortable to all users, is a personal one and should be so considered by each of us.

The application of the Golden Rule in motordom will produce golden results.

PAINTING AND FINISHING THE AUTOMOBILE

By M. C. HILLICK

APART from the propelling mechanism of the automobile and the lines upon which it is built, no feature connected with its appointments contributes more directly to the comfort, pride and happiness of its user than the painting and finishing of the vehicle. While good painting and finishing do not rectify mechanical defects, nor in the least way conceal them, they do relieve angularity of lines and design and very often confer upon an unfortunate sample of designing a distinction to which, apart from the selection of color and the luxury of finish applied, is quite undeserving.

In other words, the painting and finishing of the automobile to-day has resolved itself into one of the most essential and important features of the work involved in the manufacturing and marketing of the horseless carriage and in maintaining its appearance in active service.

In painting and finishing the automobile, there are at least three highly important—well-nigh indispensable—factors to be considered. First, durability; second, choice and distribution of color upon the surface; third, quality of finish.

It is important, admittedly, that the structure of paint and varnish, built up with such an infinite capacity for taking pains, should prove durable. Even the man with wealth to "tear down his barns and build greater," is looking for the paint and varnish for his automobile that will stand out with tenacity in the face of the most rigorous service.

In the matter of appearance, color brilliancy and disposition of color upon the surface with reference to developing all its possible charms, are advantages which even the most calloused user of the automobile will be quick to admit. An individual pride has developed along the line of creature comforts and satisfaction, as a part of automobile experience, that is creating an increased demand for all that is finest and best in color, harmony and contrast.

Apparently, it is a case in the most part, of the owner trying to outdo his neighbor in getting all the color possibilities which the painter is capable of showing and the late New York shows are in evidence to prove that the painter is developing some wonderful color effects.

Without the right quality of finish, however, all these things —quality, color magnificence and striping combinations—must prove only transitory and of small moment. With this clear knowledge of the fact, automobile buyers are daily becoming more critical, more exacting and more insistent in their conclusions as to the character of the finish belonging to the surface of the car.

No more delicate or sensitive medium is employed in connection with the construction and completion of the automobile than the varnish—the protector and beautifier of all the materials entering into what may be termed, the paint structure. That this material should be of rare quality, of a worth beyond the mere measure of dollars and cents, goes without saying. Hence it is not a question of price, but one of quality that must be taken into account in making a final estimate of the elements entering into and making up the finished product, to-day accepted as an example of the painter's art.

Of systems employed in painting and finishing the automobile there are many, although in the opinion of experts, the chief varieties may be counted upon the fingers of one hand. In point of service, as in degree of importance, the oil and lead system, with modifications making it conformable to latter day requirements, is decisively a leader. Since the ancient days, linseed oil in its absolute purity has been considered to be the life of paint, no less than it is the life of varnish. White lead, the pigment with which it serves to furnish a combination of unsurpassed merit in developing a surface upon which to lay the fields of color, is in itself a pigment in density of atoms, in fineness of body and capacity for laying close and firm and surfacing to a satiny finish, that is without a rival.

However, in response to a demand for a surfacing medium quicker in its action, harder and if anything, more economical in its surfacing qualities, there has come into the markets and into large use, patent surfacers worthy of confidence and strictly eligible in every way.

The reader may be assured therefore, that no hard and fast rule exists to govern either the car owner or the painter in making a choice of systems with which to build up the pigment structures. The main thing is to employ materials that are above suspicion and qualified to furnish a service of wear and good looks, satisfactory to all parties concerned.

The automobile with a wood body, for first class work will receive as a rule, at least fourteen coats of material to carry it through to a finish. For a finish of lesser quality, there is a system of correspondingly fewer operations, graduating down to as few as half a dozen coats, for what might be regarded as a "cheap" finish.

There is, of course, a certain class of car and a certain type of man, each of which demands cheapness, and the system referred to is designed to meet such a demand.

Of the metal bodies, aluminum, sheet steel, etc., the painter is having his full share and while the paint structure over such surface is built up from fewer coats than required upon wood, such painting must be most carefully adjusted and balanced out to a nicety and made to fit the negative surface upon which it is applied. There is a lack of receptiveness in metal, either aluminum or steel and a lack of the porous qualities of wood, both of which conditions the painter must study to counteract by special methods of mixing and application in order to realize satisfactory results in his work.

The art of painting and finishing, is one demanding the utmost attention to detail as well as general basic principle. Imperfect work in this respect has a distinct negative effect.

AUTOMOBILING AND BICYCLING COMPARED

That persistent question of whether the automobile industry will be forced to cut down its production like the bicycle makers receives a new and sensible treatment in an editorial in the March issue of *Machinery*.

"A good many manufacturers of machine tools and supplies who are selling from fifty per cent to one hundred per cent of their product to the automobile trade are asking themselves how long the demand will continue, and if it will drop off as suddenly as the bicycle trade did. We think not.

"Bicycle riding was a craze that went through a family like the measles. There were five members of the writer's family and we had five wheels. That was ten years ago, and since then a new generation of children has grown up, but they don't ride wheels. The industry is now reduced to a commercial basis, and not one rider in a hundred uses his wheel for pleasure.

"Bicycling as a fad began to expire when it became commercialized, and all sorts of people took to wheeling. The future of the automobile industry, as we all agree, lies in the adaptation or development of cars to commercial uses—not accomplished yet because manufacturers so far have been unable to supply the demand for pleasure cars, and also doubtless because of the smaller margin of profit between a luxury and a strictly commercial proposition.

"After the existing and projected automobile works are equipped, we shall have some let-up in the demand for machine tools for that purpose, but the skill of our mechanics probably will develop the automobile industry gradually and conservatively until it becomes as safe and permanent as any other."

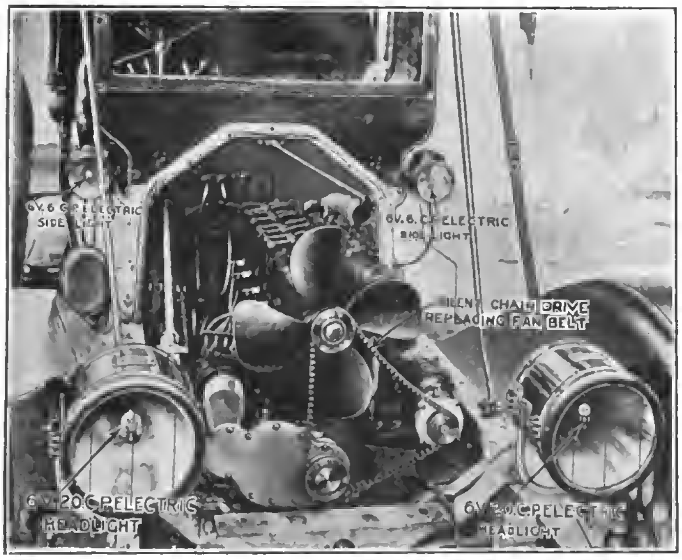

Fig. 1—Dynamo and fan driven by a silent chain taking power from a pinion which extends out on the half-time gear shaft

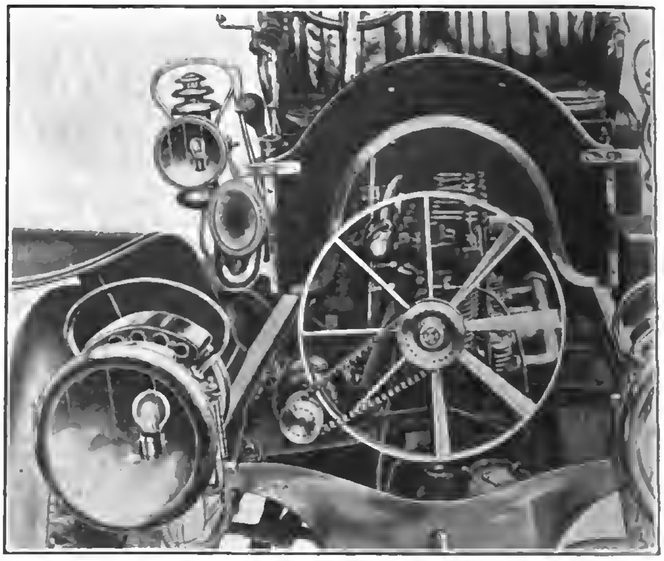

Fig. 2—Lighting dynamo driven by a silent chain taking power from a pinion which is fixed upon the fan spindle

APPLICATION OF THE APPLE ELECTRIC LIGHTING SYSTEM

TUNGSTEN lamps in view of their high watt efficiency, are the means at hand which overcome the formidable difficulties involved in the process of utilizing electric lighting in automobile work. Despite the high economy of the tungsten lamps, it is considered distinctly advantageous to float the battery on an electrical circuit which takes its energy from a charging dynamo. The dynamo is driven by the automobile motor, and is so designed and installed that the variable speed, which is essentially a feature in conjunction with the motor which drives the automobile, is compensated for with a view to delivering a substantially constant voltage of the dynamo, thus rendering it potent, either for charging the battery, or for furnishing the electric energy to the lamps direct, utilizing the battery however, as a form of stability inducer.

In the Apple system, as it is being employed at the present time, a new form of load regulator offers certain specific advantages, which is tersely described by the Apple Electric Company as follows: "As soon as the dynamo generates sufficient voltage, an automatic cut-out connects the dynamo circuit through the voltammeter to a large capacity storage battery which acts as a reservoir to accumulate the surplus current, and it supplies automatically the current for either the ignition or lighting." This arrangement permits of utilizing the energy from the battery when the dynamo is shut down.

The various methods of driving the lighting dynamo are extremely interesting, and the illustrations here afforded offer four methods in vogue, in which Fig. 1 shows the dynamo resting on an arm of the motor, and the driving chain of the silent type, meshes with a driving pinion, which is on a stub spindle, projecting out from the half-time gearcase.

In Fig. 2 it is shown that the dynamo is driven from a chain pinion which is fastened onto the fan spindle. The fan in this case takes its power from a separate source.

Fig. 3 shows the lighting dynamo driven by a silent chain, which engages a chain pinion fastened onto the shaft, which is placed to drive the magneto.

Fig. 4 shows another and very excellent variation. The lighting dynamo is driven by a silent chain, and the driving chain pinion is on the crankshaft extension which leads out to the starting crank.

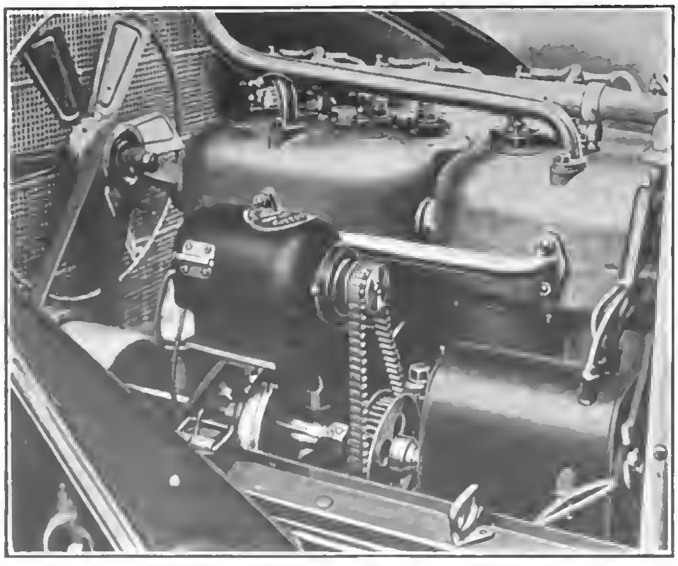

Fig. 3—Lighting dynamo driven by a silent chain taking power from a pinion which is fastened to the shaft which drives the magneto

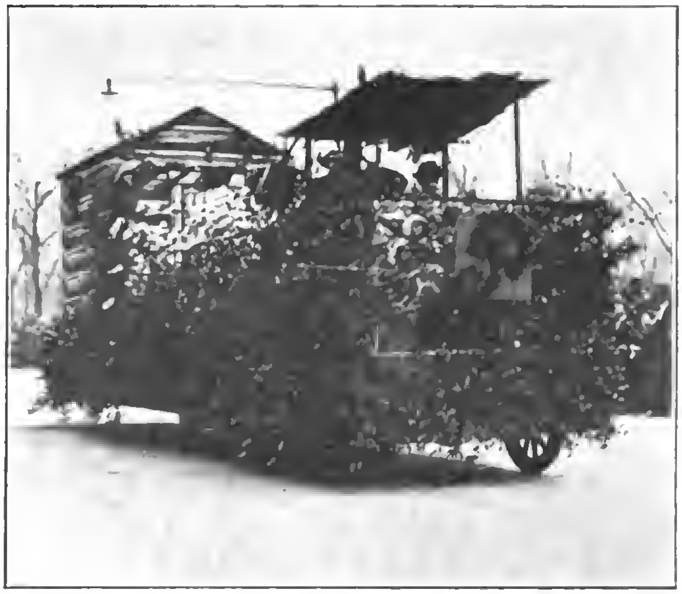
Fig. 4—Lighting dynamo driven by a silent chain which in turn engages a pinion taking power from the crankshaft direct

First Prize Car, a Chalmers Entered by Louis G. Deschler



One Premier Entry as It Appeared in the Floral Parade

HOOSIER OPENING WEEK EXCELS ITS RECORD

INDIANAPOLIS, Apr. 2—Surpassing its former efforts in the line of making its annual motor car opening week an event of importance, the Indianapolis Automobile Trade Association eclipsed its record this week. The floral parade which took place last Wednesday was one of the most striking features of the opening and the artistically decorated cars showed to great advantage.

The Packard truck and the Premier exhibits were unusual in their finery. The truck was arranged like a white battleship, armed with American Beauty roses and carrying a full brass band. The Premier car was the groundwork of a plantation scene. The Hupmobile represented a locomotive.

Each year it has been the custom for local members of the motor car trade to set aside a week for a formal opening, each concern exhibiting in its own salesroom or factory, but participating in various public events. These individual exhibitions are necessary by reason of the fact that there is no building large enough to accommodate such a combined exhibition as there would be, if all should decide to show together.

The extent of the local industry may be seen readily from the fact that more than 90 concerns are identified with the trade. There are 45 agencies representing 80 different makes of cars. There are also an even dozen factories for the manufacture of cars, and numerous concerns for the manufacture of parts and accessories, besides branch tire houses, etc.

Each year the practice of awaiting opening week before purchasing is growing in popularity and as a result the public interest in the event this year was greater than ever before. It has been estimated that 200 cars were sold.

Monday and Tuesday were devoted exclusively to the display of cars in the respective salesrooms and factories.

There were a number of gymkhana contests at the Indianapolis Motor Speedway Thursday afternoon, the speedway management having donated the grounds and no admission fee was charged. Contests were limited to stock gasoline cars with full catalog equipment. The event was in six sections.

Another event of considerable interest and importance was the review, or parade of 1910 models.

The opening concluded Saturday evening with a banquet at the Denison Hotel.

L. G. Deschler's Rapid Delivery Wagon in the Flower Event

Pittsburgh Show Proves An Eye-Opener

PITTSBURGH, Mar. 26—The fourth annual Pittsburgh automobile show opened in the spacious Duquesne Garden to-night. More than 4,500 persons viewed the $1,000,000 display. It was in sharp contrast to the scattering exhibitors who "made" the first show four years ago.

Instead of a "baker's dozen" cars on exhibit there were actually 125 models shown on the floor of Duquesne Garden, varying in cost from $450 to $7,000 and in size from the 10-horsepower runabout to the magnificent 70-horsepower touring car. Where four years ago there was not a truck shown, to-night the enterprising merchant and manufacturer had the pleasure of viewing 11 different types of commercial delivery wagons, which are fast revolutionizing the transportation methods in this hilly city. Fifty firms were on the floor with splendid exhibits of accessories, where at the first show hardly a booth was devoted to this purpose. Progress in automobiledom was evident.

Quite as striking was the wonderful advancement made in the show settings. This year the committee, composed of F. D. Saupp, chairman, G. P. Moore, James R. Newell and W. N. Murray, was diligent to make the 1910 exhibit far ahead of any other automobile show ever held in the Keystone State. Profiting by past experience they first arranged for the making over of certain parts of Duquesne Garden so as to afford more space for exhibits. As a result 40 more booths were provided than last year and even with this number nearly 60 prospective exhibitors were refused space this week. Money and pains without stint were spent on the decorations of the big Garden. Thousands of yards of gold, canary and white draperies and hundreds of bay trees and palms and monster hanging baskets of flowers gave the place a splendid Eastern appearance. High above the multitude that promenaded between the lines of costly machines hung the famous Curtiss aeroplane. In front of every exhibit hung an art glass, bronze electric light dome, suspended by massive wrought-iron chains and having emblazoned on it the name of the exhibitor.

The 1910 committee has acquitted itself most creditably in another particular. This show has been advertised. Instead of a few scattering meager notices which were easily overlooked by readers of daily papers, a campaign of publicity has been successfully waged for a month. News features were devised which made advance notices attractive reading. Every paper in Western Pennsylvania was asked to help along in the work of bringing to the notice of the general public the tremendous growth of automobile-sentiment west of the Alleghanies. As a direct result many exhibitors from the big and wealthy country towns applied for space. Dozens of dealers from these places were present the opening night and assurances received from them show that during the coming week thousands of half dollars will be turned into the show till, by automobile owners and prospective buyers who are eager to grasp this chance to inspect at a small outlay of time and money the great variety of 1911 models shown, for the majority of the cars on exhibit are next year's types.

The Standard Automobile Company had on exhibit a car, the usual brass parts of which were gold plated, giving the visitor a glimpse of dazzling automobile beauty. Racing cars were frequent in the exhibit and the latest wonders of mechanism stood alongside battle-scarred veterans which boasted of many a hard victory on the race track.

Away above all other features in the way of comparison is the exhibit of trucks at this show. The motor truck until last year never found a place at Duquesne Garden. The 1909 show boasted of two or three exhibits, which were well received, but were not strong enough to force any large measure of attention from the crowds. This year it is different. A variety of trucks is shown which rivals the exhibit of cars although the number is of course smaller. The entire front of the big hall is taken up with these exhibits, which include 11 different models.

The largest exhibit is that of the H. Lange Wagon Company, of Pittsburgh, which has the following trucks, all the property of well-known firms of Greater Pittsburgh, on show: Thirty-five-horsepower two-ton truck, $2,750, used by E. M. Diebold Lumber Company; 60-horsepower four-ton truck, $4,500, used by W. A. Hoeveler Storage Company; 45-horsepower four-ton truck, $4,500, used by Ohio & Pittsburgh Milk Company; 50-horsepower three-ton truck, $3,700, used by Edward E. Rieck Company; 35-horsepower 1,500-pound truck, $2,200, used by Edward E. Rieck Company; 30-horsepower one-ton truck, $2,100, used by Charles

Montreal Coliseum during the Recent Show, with Four Prominent American Makes Represented in the Foreground

P. Mungle & Sons; 30-horsepower, one-ton truck, $2,200, used by Wenzel, the caterer, of Braddock.

On the other side of the front entrance the Standard Auto Company shows the big Packard truck now in use by the wholesale firm of Arbuckle & Company. It is a 24-horsepower three-ton truck with a bed especially built for the Arbuckles by A. McClinton, of Pittsburgh. The Packards put their first truck into use in Pittsburgh last March. Now they have 11 in use here and are building four more to contract.

Adjoining the Packard display are two types of the White truck, the agency for which has just been established here. They are a $3,000, ton and a half, gasoline truck, which may be fitted with a wide range of styles of body and their three-ton gasoline truck with standard platfrom body, selling for $3,850. At the other end of the hall near the orchestra, the Overland 25-horsepower truck, seating two and selling for $1,100, is shown by the Keystone Automobile Company, of Pittsburgh.

Increasing interest in automobile matters is shown not only in the attendance at the show but also in the number of agencies which have been placed within the past week and most of which were making their initial bow to the Pittsburgh public to-night. Some of the most important of these are the following: Reliance truck, which will be handled by a new company composed of H. C. McMasters and P. K. Soffel, of the Wabash-Pittsburgh Terminal Railroad Company, and others; the Overland truck, with the Keystone Automobile Company; the White Company's truck agency; the new Whiting-Pittsburgh agency; the Abbott-Detroit, which will be handled by the Forbes Motor Car Company; the Sebring-Pittsburgh agency; the Krit car, to be sold by the Forbes Motor Car Company, and the Hygay electric outfit.

Following is the list of cars exhibited:

Abbott-Detroit, Atlas, Autocar, Baker Electric, Brush, Buick, Chalmers, Columbia, Corbin, Courier, Croxton-Keeton, Elmore, E-M-F, Flanders, Ford, Franklin, Hudson, Hupmobile, Enger, Inter-State, Jackson, Kline, Knox, Krit, Locomobile, Marmon, Maxwell, Mitchell, National, Otto, Overland, Parry, Paterson, Packard, Peerless, Pierce-Arrow, Pittsburgh Six, Pope-Hartford, Premier, Pullman, Rambler, Rauch & Lang Electric, Regal, Reo, Sebring Six, Speedwell, Stearns, Stevens-Duryea, Studebaker, Studebaker Electric, Thomas Flyer, Waverley Electric, White, White Steamer, Whiting, Winton and Woods Electric.

List of accessory exhibitors: Ætna Insurance Company, Airtight Steel Tank Company, Atlantic Refining Company, Automobile Accessories Company, Banker Wind Shield Company, Brictson Manufacturing Company, Buick Motor Company, Pittsburgh Branch; Cleveland Chain and Manufacturing Company, Doubleday-Hill Electric Company, Ernst Flentje, Gasoline Motor Efficiency Company, James L. Gibney & Brother, L. Giesenkamp, Sons & Company, Hydraulic Oil Storage Company, Greater Pittsburg Auto School, Kent-Bell Company, Kerr-Griffin Vulcanizing Company, Kilgore Manufacturing Company, Motor, Miller Rubber Company, Mutual Manufacturing Company, Petroleum Products Company, Pittsburgh Auto Tire and Equipment Company, Pittsburgh Rubber Company, Reinforced Brazing and Machine Company, Rogers Printz & Company, J. A. Salman, Standard Auto Company, Star Rubber Company, E. J. Thompson Company, Westinghouse Electric and Manufacturing Company, Joseph Woodwell Company, Wright Wrench Company and N. H. Wishart.

List of truck exhibitors: H. Lange Wagon Company, Standard Auto Company (Packard truck), White Company (Pittsburg agency), and the Keystone Automobile Company (Overland truck).

Canadian National Show Held in Montreal

MONTREAL, Apr. 2—The Automobile and Boat Show of the Automobile Club of Canada closed to-night after a week during which former attendance records received a severe shock. No attempt has been made to give the Coliseum the appearance of an apple orchard or rose garden; the decorations were simple and businesslike. Draped bunting concealed the roof beams and was festooned along the sides of the hall, and three rows of signs of the severest uniformity traversed its length.

The exhibits were more international in character than usually seen. Of course American makers were in the majority, both those imported from across the line and those made in Canadian factories to escape the duty. Among the latter the McLaughlin-Buick and the Canadian Regal were prominent. Packard, Knox, Franklin, Maxwell, Oldsmobile, Simplex, National and Hupmobile all were extensively represented by their agents.

The native Canadian industry was represented by the Russell and the Comet, both cars of creditable workmanship, and following European lines to a considerable extent in their design. Charron and Renault represented the French industry, and several English makers turned out to seek the colonial trade. Along the sides of the hall, where the accessory dealers exhibited their wares, one might have thought himself in the New York or Chicago shows, so completely had the American makers monopolized the spaces. The show is regarded as a complete success from the financial and commercial points of view, and the show committee and E. M. Wilcox, the energetic manager, are receiving many congratulations.

Another View of the Montreal Show; Renault, Packard, the Canadian Buick, and Russell, a Home Product, Appear

SHARP FIGHT ON AUTOMOBILE CLUB OF FRANCE

By W. F. BRADLEY

PARIS, Mar. 28—After having had undisputed control of the automobile industry of France and also possessing a powerful influence over the national clubs of Europe, the Automobile Club of France has now to fight for its existence. For eleven consecutive years it has organized the brilliant exhibitions in the Grand Palais, looked upon by other nations with respectful awe; it has had complete control of the racing situation, has decided under what conditions races should be held, and merely by its decree has brought all racing to a stop throughout Europe. In France it was impossible for any move to be made or any scheme of importance to be put on foot without the approval of the Automobile Club.

Now its authority is being disputed everywhere, and curiously, the manufacturers who formed its committees and are still among its members, are the most active in fighting the oldest established automobile organization in the world. After a very severe fight the club has had to abandon the annual show held in the Grand Palais to a joint committee of manufacturers. The club announced an exhibition as usual, but the makers banded themselves together and refused to take part in any exhibition other than one held entirely under their own management. After a long fight the club has to agree to withdraw with the meagre satisfaction of patronizing the makers' show and appointing the honorary president. It will have nothing to do with the management and will have no share whatever in the profits of the undertaking.

The Automobile Club of France is now being attacked by the aeronautical manufacturers, who accuse it of a policy of grabbing after aeronautical control. In a letter just sent by Robert Esnault-Pelterie, president of the Aeronautical Manufacturers' Association, an ultimatum is presented to the club to cease to occupy itself in any way whatever with aerial navigation. In very vigorous language Esnault-Pelterie declares that the Automobile Club of France added an aero section to its Salon in 1908 merely to get control of the field, that in 1909 it did its best to oust the aeronautical manufacturers, and that this year it has just been baffled in an attempt to run an aeronautical show.

Before the Automobile Club was defeated in its recent fight with the manufacturers, the latter had entered into an agreement with the aeronautical men to join them in a joint aero-automobile show in the Grand Palais, as a rival to the one promised by the club. The club having withdrawn its show, and given its patronage to the constructors' exhibition, these latter asked to be freed from their contract with the aero men. Esnault-Pelterie replied that he was quite willing to set them free from their contract, but only on condition that the Automobile Club of France should cease to have any further connection with the aeronautical industry. "You are an automobile club; stick to your automobiles," he declares, "and leave us, who know something about flying machines, for we risked our lives in them while you sneered at us, to develop aerial navigation according to our own views."

An immediate reply has been asked for, but up to the present the club has not taken any official notice of the letter.

AERO ACTIVITIES INCREASING IN GERMANY

BERLIN, March 28—In response to a general demand, the German Wright Company has begun to fit wheels to its aeroplanes, as it is far easier for a novice to learn on an apparatus with wheels than without. The principal drawback of the earlier method was the necessity of taking the first flights with an instructor, and as the number of experienced teachers is very small compared with that of the pupils, many of the latter were forced to wait an undue time for their turns.

German aeronautics have suffered a great loss in the death of Lieutenant-Colonel Moedebeck, who on retiring from the army nearly fifteen years ago started the first aeronautic magazine in Germany, which he edited to the time of his death. He was the writer of various valuable handbooks and treatises, and it is largely due to his unflagging activity that aeronautics of all kinds have spread so generally throughout Germany. Colonel Moedebeck was a member of several international commissions.

Two resolutions have been unanimously accepted in the German parliament concerning the erection of an Imperial Institute for Aeronautics and Aero Technic at Friedrichshafen. Although this city is the scene of the Zeppelin activities, the institute will naturally be open to all makes and types of aeronautic apparatus. An imperial commission is to be called by the Government to debate on ways and means. Count Zeppelin has declined the presidency owing to pressure of business.

FARMAN PUPILS OUTSTRIP THEIR MASTER

RHEIMS, FRANCE, Mar. 28—Van den Born, formerly racing cyclist, later aviation pupil, now instructor at the Farman school, has surprised his master by making a cross-country flight from Mourmelon to Rheims and return, a total distance of nearly 40 miles. The outward trip passed without incident, and when the suburbs of the champagne city were reached the military quarters were selected as the most suitable place for a descent. After lunch the return journey was commenced, but it was not long before the pilot discovered he had hopelessly lost his bearings. A landing had to be made near a village which proved to be the name of Prosnes; villagers assisted in the unusual task of starting the Gnome motor, and with directions as to his route a safe return was made to the aviation ground.

Georges Chavez, another Farman pupil, with only six lessons to his credit, has succeeded in creating a record of 1,670 feet in height over the Mourmelon aerodrome. The height was recorded by a registering barometer. Chavez, who is a young athlete of Peruvian origin, declares that he will go after the records for altitude now held by Paulhan and Latham. He has already made a cross-country flight of 1 hour 47 minutes in duration.

ROUGIER'S FLIGHTS STARTLE RIVIERA

Monaco, Mar. 28—Henri Rougier, one of the most brilliant of automobile race drivers of the Gordon Bennett and Grand Prix period has startled the Riviera by flights over the Mediterranean and the mountainous coast of Monaco, Monte Carlo and district. A year ago valuable prizes were offered to the aviators who would fly across Monaco Bay and return, a distance of less than five miles. Although about 30 entries were received not a single machine ventured forth, owing to the exceptional difficulty of making a start and coming back to earth. Monaco nestles on the edge of the Mediterranean at the base of a cliff rising almost vertically to a height of 3,000 feet; Monte Carlo adjoining it, rises tier upon tier on a picturesque mountain side. In the whole district there is not an acre of level ground, and the only level street is the *quai* about 300 yards in length, with the castle promontory rising up perpendicularly on one side and a well filled harbor on the other. It is necessary to make a start on this, with the certainty that if the machine runs to the left it will drop into the harbor, if it deviates to the right it will smash itself to pieces against the granite walls of the castle, and if it does not rise rapidly it will collide with the sea wall forming a barrier across the end of the jetty.

Rougier believed that with his Voisin biplane and Gnome motor he could rise from this ledge and fly over this mountainous coast. He proved it. His machine was brought from Heliopolis, where strong winds had made flights over the desert a difficult matter. It was erected, the motor tested, and there being no place available for a trial flight, sent away for a trip across the sea. After a run of less than 200 yards the machine was in the air, had cleared the sea wall 30 feet high with a safe margin, and was directly over the Mediterannean at a height of 300 feet. In a few minutes he had reached Cape Martin, on the opposite side of the bay, rounded it, returned and flown over the town of Monte Carlo, steered out to sea, described a curve in order to get in line with the jetty, and descended on the ledge at the door of his shed with remarkable ease. On the two following days a strong wind prevailed, making flights impossible. During this interval, and while testing the motor, the mechanic lost the tips of two fingers, chopped off by the whirling blades of the propeller. On three successive days flights were made across the bay under practically the same conditions as on the first occasion.

Then Rougier prepared for a more sensational exploit. He got away from the *quai* side, flew over the bay in an easterly direction and began describing wide circles until he had attained a height of almost 3000 feet. He was then but a speck against the bold outline of the mountain range and from below appeared to be almost level with the top of Mount Agel, 4,000 feet above sea. Following the range of hills dominating the bay he continued eastward, passing over the Turbie, up which he had many a time raced in hill-climbing competitions, then reached the French fort on the top of the Tête de Chien, a mass of rock rising almost vertically from the sea to a height of 2000 feet. By the aid of field glasses it was possible to see the soldiers standing on the fort waving their hats to the aeronaut passing over their heads. By reason of the wild nature of the country it is a matter of two hours to travel by automobile from Monaco to the fort, only 2,000 feet away; by horses the journey occupying four or five hours. Rougier, on his Voisin biplane, flew over the fort within twenty minutes.

The descent was a matter of a few minutes. the aeroplane sweeping down over the town, passing out to sea again, flying over the Prince of Monaco's palace as it did so, then coming inwards in a line with the jetty. On the next occasion a trip was made along the coast in the direction of Italy, the aeroplane flying over the sea until the port of Mentone was reached. This was rounded, the return trip commenced and when near Monte Carlo the aeroplane swept to the right to pass directly over the casino and gardens. While in this position the motor was stopped for a few seconds, to the consternation of the spectators, who believed that a serious accident had happened. But the current was switched on again before the aeroplane had dropped far, and five minutes later Rougier had landed with the remark that he had just been taking a little trip for the sake of his health. These flights are regarded as the more remarkable for the reason that the Voisin biplane has neither *ailerons* or plane-warping to secure stability, and has always been considered a fair-weather machine.

LENGTHENS LIFE OF OLD TIRE COVERS

Paris, Mar. 28.—Since the day when the Davies Brothers put the Stepney emergency wheel on the English market there have been numerous copyists in various parts of the world. Most of these have merely sought to produce a spokeless wheel which, as in the case of the Stepney, would allow the car to be run home without work on the tires, after a puncture. The Houdaille, just produced by a French firm, claims to have a wider field of usefulness, for as it is secured to the outside of the rim, and not hooked to the inside, it can be attached whether an inflated or a deflated tire is in position. This allows it to be used temporarily where a non-skid is required on a car, the four wheels of which are shod with smooth tires.

It allows of twin tires for the rear, when a temporary. heavy load, has to be carried, and it further allows old covers to be used up in pairs for town work, which would certainly burst if run singly over country roads. The makers attach considerable importance to the device as a commercial accessory, for on delivery vans it frequently happens that a car has to be overloaded in a manner that is apt to be injurious to its tires. If the Houdaille wheel is added with the extra load, the weight is carried better and the covers do not suffer.

As in all other devices of this nature, the Houdaille consists of a steel rim, without spokes, on which a fully inflated tire is mounted ready for use in case of emergency. Its individuality lies in the method of attachment. There are no permanent lugs to the rim, with jaws for clamping to the road wheel, but in its place a steel tube triangle, at each angle of which is a forged steel wedge of special shape. Two of the wedges are pivoted to the angle of the triangle, while the third is secured by a strong bolt screwing through the body of the frame, and entering into the wedge.

The shape adopted for the wedges is such that one half presses against the inner face of the movable rim, and the opposite half against the corresponding portion of the fixed steel rim.

It is shaped in such a way that it enters between the spokes of the wheel and surrounds the wooden felloe. When in position and screwed up by means of an ordinary spanner, pressure is applied to the two rims at three different points on their circumference. A couple of studs project from the face of the spokeless rim and thus act as an additional guard against the wedges slipping.

In reality the rim becomes a wheel with three spokes, and is almost as solid in construction as one of the car wheels. When once the pressure has been applied it is impossible for the wheel to slip unless the pressure is relaxed, and this is prevented by a suitably shaped plate fitting over the head of the bolt, secured there by two springs, and further held by a thumbscrew. When not in use, the spare wheel can be attached to a special triangular carrier designed for that purpose and secured to the side of the car, or the triangular attachment may be dismounted, and the whole carried in the same way as a dismountable rim.

New Idea in Carbon Removal

Editor THE AUTOMOBILE:

[2,214]—In the February issue of "Motor," under the title of "An Original Carbon Remover," appears an article by A. D. Hard, in which he advises the placing of a small steel ball, about 3/16 inch in diameter, in the cylinder above the piston. He claimed that the bombarding action of this ball would serve continuously and effectively to keep the combustion chamber, the end of the piston, and the exposed surface of the valves completely free from carbon deposits without any further attention. This appeals to me a very simple remedy for the carbon trouble, if no damaging results could come of the loose ball in the combustion chamber. I am the owner of a Maxwell Model E touring car, and would like to give this method a try, if in so doing I would run no risk of damaging the engine. Would you kindly advise me through the columns of "Letters Interesting Answered and Discussed" of your paper? A. R. L.

Bay City, Texas.

Best of all ways to solve this is the method of trying it. There is something in what the writer says about the action of the gases and the position of the ball at the time of valve opening which tend to keep the ball in. The only danger you would be exposed to would be the destruction of your valves through the ball getting to the seats and sticking there. It may be that this cannot happen, as the writer of the article in question says. On the other hand, this would be noisy in a multi-cylinder engine.

Proper and Improper Tire Pressures

Editor THE AUTOMOBILE:

[2,215]—Since January 1st, when I became a subscriber to "The Automobile," you have several times spoken of the advisability of keeping tires pumped up hard, that is, to a uniform and proper pressure, but I have never seen an article which gave the specific tire pressures for different tires, under maximum loads. My car is a Ford Model T, with tires 30 by 3 on front wheels and 30 by 3½ on the rear. The maximum load carried on the tires is about 2,050 pounds. Please let me know through your column of "Letters Interesting Answered and Discussed" the proper pressure for these tires: also, if an extra weight of 150 pounds could be carried without overloading tires as small as these. CHAS. B. FOSTER.

Water Mill, N. Y.

Tables of tire pressures have frequently been published, but the pressure and carrying capacity of this sized tire will be given again. Thus, one maker recommends for 30 by 3 tire 65 pounds pressure and give it 350 pounds carrying capacity. For 3 1-2-inch tires the pressure figure is raised to 80 pounds, while the carrying capacity rises to 450 pounds. This would make the whole carrying capacity of your four tires amount to two times 350 plus two times 450 or 700 plus 900, a total of 1,600, which would then allow you much more than 150 pounds overload.

Wants Address of Runabout Maker

Editor THE AUTOMOBILE:

[2,216]—Will you please inform me through "Letters Interesting Answered and Discussed" where I can secure a complete description of the "Billy Four," or give me the address of the maker or of some agency from which I could get the information?

Lyons, O. F. H. CARPENTER.

The "Billy Four" is made in Atlanta, Ga., and is sold by the American Sales Company, of the same city. You will find a description of it, in tabular form, in the tables of specifications in THE AUTOMOBILE issue of February 3.

Getting Into the Automobile Business

Editor THE AUTOMOBILE:

[2,217]—Will you kindly give me some advice through "Letters Interesting Answered and Discussed"? I have made a careful study of the automobile and am familiar with every bolt or piece of mechanism in one. I am eighteen years old and have a good education; have had some experience at driving and some at repairing and am prepared to do anything of the kind. What would you advise me to do in order to obtain a permanent foothold in the automobile world? READER.

Hudson, Mich.

The automobile industry is large enough for a man to make a success in it in a number of different ways, each requiring talents of a different sort. What you should do to gain a foothold naturally depends on which of these lines you wish to enter. Do you wish to be a designer, a factory manager or superintendent, or a salesman?

For the automobile designer a college education, leading to a degree of M. E., may be regarded as essential. Although automobile design in the past has been largely a matter of rule of thumb, it is rapidly becoming more scientific, and the man who wishes to make a success at it should have the best possible engineering training. Another way of beginning, which would more naturally lead to the position of factory superintendent, would be to start at the bottom as an apprentice or helper in some automobile factory.

The natural way to become a salesman is to sell cars, by securing a position in that capacity with an agency or selling branch. Starting with a position in a small agency, a man of the requisite ability would soon rise to positions in larger cities, in branches controlled directly by the manufacturing company, and from there would graduate into the organization of the company itself.

Presidents of companies come both from the manufacturing and from the selling ends of the business. Sooner or later, the man who possesses the executive ability to handle a large business will get an opportunity to show it, and recognition will follow, whether he be a designer, or a salesman. If he should have the training of both, so much the better.

Formula for Heat-Resisting Paint

Editor THE AUTOMOBILE:

[2,218]—Will you kindly give me through "The Automobile" a formula for a fireproof paint that will resist the heat on the exhaust manifold of my engine? H. L. LANG.

Staunton, Va.

Although there are many formulas which could be used for the purpose, all require a disproportionate outlay for the ingredients, besides the trouble of mixing. The most satisfactory paint for such purposes, all things considered, is ordinary stove polish, such as can be purchased at any hardware store, or can probably be found in your kitchen closet. If the exhaust manifold is badly rusted, the rust should be cleaned off with a stiff-wire brush, or by scraping with the back of an old knife. The polish will also be found to improve the appearance of the whole cylinder castings.

Relation of Power to Speed

Editor THE AUTOMOBILE:

[2,219]—To settle a dispute, will you please state, in "Letters Interesting Answered and Discussed," if an ordinary gasoline motor develops its maximum power at its maximum number of r.p.m., or when running at a lesser speed. H. STEINER.

New Haven, Conn.

The exact answer to this question depends entirely upon the torque curve of the engine, and this curve varies with each and every different engine, so that it would be necessary to have a large number of them in front of one, before even an average answer could be given. Speaking very generally, the maximum power does coincide somewhat closely with maximum speed although there are numerous instances to the contrary.

Estimated 1910 Car Production

Editor THE AUTOMOBILE:

[2,220]—Will you please tell me the six greatest manufacturers of automobiles in the United States, and the production of each per annum? What is the best automobile on the market.

Cleveland. ERNEST VOLGER.

If you have reference to quantity, approximate figures on the 1910 production of some of the largest American producers are as follows:

Ford, 20,000; Buick, 20,000; E-M-F, 18,000; Willys-Overland, 15,000; Maxwell-Briscoe, 22,000; Reo, 12,000; Cadillac, 8,000; Jackson, 6,000, and Mitchell, 6,000.

The above figures are of course approximate, for it is impossible to obtain a correct and exact estimate of the number, as the manufacturers themselves seldom know to within a hundred or so of the number of cars which they will produce.

As to the best car, that depends entirely upon the price, and even knowing the specific price you wished to pay, it would be a very hard matter to determine. Picking the best car is like selecting the best location for a house, or the best kind of a house to put on the location, when the latter is selected, or many other things in which personal prejudice may enter. In short, it is only a relative matter, what would seem best, at any one price and in any one class, would probably not suit your neighbor at all.

Remedy for Trouble with Soot.

Editor THE AUTOMOBILE:

[2,221]—In referring to the December issue of "The Automobile," page 1049, in which F. N. P. is having trouble from soot in his two middle cylinders, I wish to suggest that he is likely using a single carbureter for the four cylinders. The two middle cylinders being nearer to the carbureter than the end ones would get a higher mixture, thus causing carbon deposits. Would suggest using two carbureters. W. H. HARRIS.

Morris, N. Y.

The cure is worse than the disease, that is, there would be more trouble experienced with the adjustment and use of two carbureters than is the case at present. If the above is the true source of trouble, a better and cheaper way would be to design and have cast and machined a new inlet manifold which would not have a differing distance from the carbureter in the four cylinders. For this purpose, the loop shape is much favored, and is being slowly used more and more.

On six-cylinder engines, in particular, the matter of proper charge distribution has been investigated with great thoroughness, makers going so far as to construct and try out all possible shapes which could have a good influence. Some of these had no direct result, while others showed merit by an increase in the amount of power developed, in speed, and otherwise.

Basic Carbureter Patent

Editor THE AUTOMOBILE:

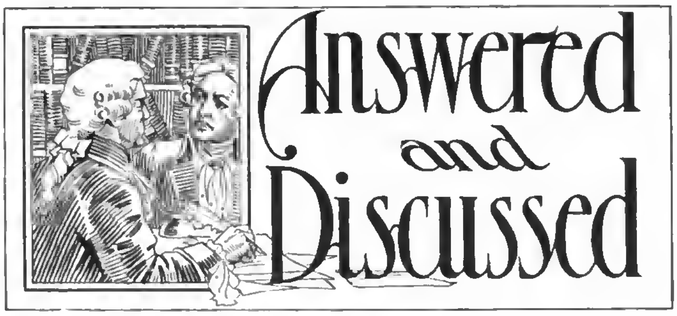
[2,222]—I would like to know if there is a patent still in force which controls in any way the using of floats in carbureters? Would also like to know the name of some firm manufacturing floats. Please answer in your Questions column. R. S. HILL.

Des Moines, Ia.

No, there is no basic patent now in force on the use of a float in a carbureter. This may be reasoned out by inference, from the fact that all carbureters have floats, while nearly all companies making them are competing with one another. Obviously this could not be the case if one held a basic patent on the use of a float.

To secure a basic patent, it is necessary for one to have either a new and decidedly different idea, or else, a new and decidedly different combination of old ideas. Since the first carbureter, that of Maybach in 1884, had a float, it was impossible for anyone to patent its use after that time.

You may obtain cork floats from the Armstrong Cork Company, Pittsburgh, Pa., while nearly any tin shop will make copper floats for you.



Flywheels and Gyroscopic Force

Editor THE AUTOMOBILE:

[2,223]—I will be greatly obliged if you will answer the following questions in "Letters Interesting and Instructive":

1. Would it be possible to run a 60-pound vanadium steel wheel 22 inches in diameter (weight concentrated at the rim as far as possible) between 4,000 and 5,000 r.p.m.? Would it be safe?

In your issue of January 20, 1910, you state that the safe rotative speed is $\frac{6{,}000}{\text{circumference of flywheel in ft.}}$ for cast-iron. My reason for writing is that I have been unable to find out the relative strengths of cast-iron and cast-vanadium steel.

2. If the above wheel is running in a vertical position how much pressure (in pounds) would have to be applied at the end of a lever 15 feet long to move it towards the horizontal plane? If there is a formula for this please state it.

New York City CHARLES E. JONES.

The strain on a flywheel rim due to centrifugal force is expressed by the formula $S = .00005427WRN^2$, in which S is the strain in pounds, W the weight of the wheel in pounds, R the mean radius of the wheel in feet and N the number of revolutions per minute. The formula you quote is derived from this by finding the strain per square inch of sectional area of a cast-iron wheel, which would be $S_1 = .000027V^2$, in which V is the velocity of the rim in feet per minute; it has been found that a tensile strength of 10,000 pounds is all that can be reasonably assumed, and taking a factor of safety of 10, $1{,}000 = .000027V^2$, whence $V^2 = 1{,}000 \div .000027$, and $V = 6{,}085$.

Taking into account the greater weight of steel, the strain per square inch of a steel wheel would be $S_1 = .000029V^2$. The determining quantity is then the tensile strength of the steel which you wish to use, divided by a reasonable factor of safety. Your 22-inch wheel turning at 5,000 revolutions would have a peripheral velocity of 28,800 feet per minute, which by the formula above would give a strain per square inch of 24,000 pounds. Whether this would be safe or not depends of course on the steel. "Vanadium steel" is a rather indefinite term, as vanadium is frequently used in combination with either chromium or nickel, or with both, resulting in considerable differences in the properties. However, you should be able to get a tensile strength of 100,000 pounds.

Your second question is not clear. A gyroscope, for as such you evidently wish to consider the flywheel, tends to keep its axis paralled to its original position; it offers no opposition to any movement which would not have the effect of changing the line of the axis. Thus, when a gyroscope is rigidly fixed in a car or boat with its axis vertical, it resists any swaying movement, but not forward or backward or up and down movement.

Editorial Note.—Many letters intended for use in these columns are received without a signature or anything to show by whom they were written. In the future, such letters will not be answered unless accompanied by the true name of the writer. If desired, this name will not be published, and a nom de plume will be used. Nor can the letters be used in the immediately following issue, for the supply on hand at all times is such as to preclude the possibility of this, unless some were used out of the order in which they were received. Obviously this would not be fair to all those concerned.

Concerning Pending Federal Legislation

By XENOPHON P. HUDDY, LL.B.

A BILL has been introduced in Congress by one of the prominent automobile organizations providing for a Federal automobile license, such as is indicated above, and this bill proceeds on the theory that interstate travel for pleasure by means of an automobile constitutes interstate commerce. Another automobile association has also introduced a Federal bill which does not include the traveler for pleasure. Since most of the interstate automobile travel is for pleasure it would be practically useless to have a Federal law if this class of travel is not taken care of. How can this be done?

Of course, if Congress is to enact legislation of this character the power to do so must be clear, since our national legislative body will not enter upon the business of passing statutes of doubtful validity. It is claimed that since interstate automobile travel for pleasure constitutes interstate commerce, the power of Congress undoubtedly exists. It is agreed that the Supreme Court of the United States has practically established the law to the effect that interstate transit or intercourse or communication comes within the constitutional provision granting to the Federal Government exclusive power over interstate commerce. It is conceded that the telegraph, the telephone, the steamboat, the railroad train and other instrumentalities of communication between the States have been held to constitute means by which interstate commerce is carried on. It has also been decided that persons walking to and from their homes and places of business morning and night over a bridge spanning a river separating two States are engaged in interstate commerce. It is obvious, however, that in all the decisions of the Supreme Court of the United States, the facts in each case had something to do with business or showed something done in pursuance of the execution of something pertaining to commercial activity. Our highest judical tribunal of the land has not gone so far as to say that a mere stroll or ramble across the boundary line of a State constitutes interstate commerce. Moreover, this never will be the law any more so than insurance is interstate commerce. This latter proposition the Supreme Court has decided. So it will be seen that to frame a Federal automobile license law on the theory that interstate touring constitutes interstate commerce is radically a wrong foundation to base such a proposed enactment on. There is another method, however, by which the same end may be gained.

It is conceded that Congress has jurisdiction over the actual interstate commerce carried on over the highways and roads leading from one State into another. That there actually exists such commerce must also be conceded. Trucking is constantly carried on over interstate highways. Stage coaches are being run. Express companies operate their vehicles. Mail wagons carry the mail. Delivery wagons from stores deliver packages. Electric trolley cars carry passengers and freight on many roads which run from one State to another.

It may be asked whether the interstate commerce which concededly is to be found on the ordinary land highways of travel running from one State to another may be protected by the United States Government. Most certainly it can be. Any interstate or foreign commerce, not only may be protected by Congress, but it may be controlled. We need not dig into the law reports to support by authority this proposition. Admitting that we have established the existence of interstate commerce on the public highways and the proposition that Congress may protect it, we will now develop our argument and ascertain further what might be done by Congress in surrounding this commerce with protection. I may add that the mere fact that interstate commerce may be found, or perhaps I would put it a little stronger, might reasonably and probably be found on any interstate way, would give Congress the power to legislate against any other traffic which might injure or affect that commerce coming in contact with it.

The fact that interstate travel for pleasure by means of the automobile does not constitute interstate commerce, prohibits Congress from directly granting a Federal privelege to an automobilist. But the fact that an automobilist runs his motor vehicle on an interstate highway where interstate commerce is actually being carried on, will not prevent Congress from enacting legislation, regulating the automobilist so that he is compelled to drive his vehicle so that interstate commerce will be protected.

We will assume that there is a certain road leading from one State directly into another. We will also assume that on this road a great deal of trucking is being carried on, a trolley road is carrying passengers throughout the day, express wagons are running and store delivery wagons are constantly driving back and forth across the boundary line of the State; at the same time, we will also assume that on this public road motor vehicles pass by the hundreds every day and that the occupants thereof are out for pleasure. It makes no difference whether the vehicles are propelled by power or drawn by animals, if any vehicle on that road which is being driven for pleasure should run into and damage one of the vehicles which is being operated for the purpose of commerce (which is likely to occur) it can readily be seen that Congress would possess the power to regulate a certain class of vehicles which travel for pleasure over interstate highways so as to insure protection to other vehicles which are engaged in interstate commerce.

The present bill of the American Automobile Association permits an automobilist who is duly licensed in his home State to obtain a Federal license. He is not restricted. He obtains an additional privilege. He gets this not because Congress desires to protect interstate commerce, but because the American Automobile Association says that automobilists who are engaged in interstate travel for pleasure are carrying on commerce. If such a proposed law provided that the automobilist must obtain a Federal license and carry a Federal tag, which would identify him in case he committed injury to any vehicle engaged in interstate commerce on an interstate highway, then the law would be valid and constitutional, since it seeks to protect interstate commerce. It is upon this theory alone that a Federal registration bill can be constitutionally enacted. The same results practically would be accomplished as sought in the American Automobile Association's bill. With the mandatory requirements would be conferred the interstate license as an incident.

Great care should be taken in framing a bill of this character. The proposed law should define what constitutes interstate highways or roads. It should be provided that all public highways and roads which directly lead from one State into another are interstate highways for the purposes of the act. The term interstate highways should also include all other streets, roads and highways which lead into any main or direct interstate highway running from one State to the other, and which are necessary or convenient in the use of said main or direct road or highway. Congress once having declared what constitutes interstate highways will then have the power to control travel thereon fully. It must not be forgotten that a person is engaged in interstate commerce if he is traveling wholly within the limits of a State or within a municipality thereof, if he is at the time engaged in a general business which is interstate in its character and his traveling is a necessary part of that business. I will make this assertion and I feel confident that I can back it up by authority, that, if I drive a wagon in the city of New York continually for four days in a week collecting packages which I expect to deliver and sell in the city of Paterson in the State of New Jersey, I am engaged in interstate commerce while I am so driving in New York City and Congress may protect me from injury which might be done to me by automobilists traveling on the city streets, compelling them to take out a Federal license.

Manufacturers' Opportunities the World Over

WASHINGTON, D. C., Apr. 4—The following report covering the market for automobiles and traction cars in Portuguese East Africa, transmitted by Consul George A. Chamberlain, of Lourenço Marquez, contains interesting information concerning the conditions which prevail in that colony and the cause why American cars are not in more general use in foreign markets:

Up to a few years ago the streets of the city of Lourenço Marquez, the capital of Portuguese East Africa, were mere rivers of sand, and transportation by automobile seemed as far off as aerial navigation. The white man was hauled laboriously through the sand in rickshaws, and women went shopping swung from Kaffir-borne poles in hammocks known as *mechillas*. During the last decade, however, wonderful changes have taken place, so that to-day Lourenço Marquez has 40 miles of macadam streets, with promise of more to follow. Sand is the curse of Portuguese East Africa. It blocks the rivers and harbors and stretches in a vast sea toward the interior, effectually cutting off the coast towns from the highlands. Besides, it makes the problem of transportation the bugbear of the planter.

The stone for macadamizing the streets of Lourenço Marquez was brought 50 miles by rail from the borders of the Transvaal, and the hauling from the local station to the place of application cost more than the quarrying, crushing and transportation by rail put together.

The transport problem of the district is further complicated by the diseases that have decimated the cattle and horses all along this coast. He who buys a horse takes an 8 to 1 chance of burying him within a year. Horse sickness defies the most careful nurture, and is still, in every feature, a mystery to science. It is said that only 2 per cent. of the stricken recover. As to cattle, the danger of loss is no less, as the mere fact of the infection of a district condemns a farmer to the disposal of his entire stock. The situation resolves itself into a choice between automobiles and donkeys, and in Lourenço Marquez and vicinity the automobiles are winning. Of the automobiles already here, one is of American make and would cost at home about $750, but so strangely do our manufacturers arrange their export business that the middleman's commissions and duties brought up the cost of the car to the local purchaser to about $1,400. During the present month—November, 1909—four automobiles have made their appearance on the streets of Lourenço Marquez, and a truck of very special construction is on the way to start the battle against the 18-inch sand of the suburbs. The truck was ordered by the local government from a European firm. The contract is most interesting. The purchase price is fixed at about $15,000, to be paid in three installments, as the car succeeds in performing the various feats of the guaranty. This guaranty assures, among other things, a carrying capacity of 4 tons through 18-inch sand at 8 miles an hour, a hauling capacity of 8 tons, and the performing of a trip under test conditions to the suburb of Marraquene, 19 miles out.

DEMAND FOR CHEAP CARS

There is a limited market here for a cheap grade of car suitable for running around town. Four have come in this month, and it is safe to predict that next year will see this number increased by twenty. The market for traction, freight, and agricultural cars, if properly worked, is unlimited. Horse sickness and tick fevers will prove unfailing allies to the manufacturer.

Some American car manufacturers have seen fit to sell their export business to New York commission houses. The manufacturer reasons thus: It costs him $800 to turn out his car. A big commission house agrees to give him $1,000 per car if it be made sole export agent. He thus makes a solid profit and is free from the trouble of studying export and founding an export department. He signs a contract and thinks he has made a successful deal, but that contract is to a large degree the destruction of his export business. The commission house takes over the car at $1,000, and contracts agencies with established firms all over the world, fixing the retail price at $1,500. The agency gets a net sum of $75 per car sold. Charges, insurance, freight, and duties, say, $225. The commission house pockets the difference, $200, just what the manufacturer made on his car.

LIMITED AGENCIES DESIRABLE

Anyone can see the dire effects such a line of procedure will have upon American competition abroad. Our medium-priced cars are wonderfully suited for the capture of new markets if they can be sold as medium-priced cars. The only way to assure this is by the establishment of direct limited agencies and undertaking the local advertising. The latter stipulation is unusual, but most important. In the first place, the American conception of advertising is just sifting into the outer world. In the second place, a foreign agent is interested in American goods solely through his pocket. He is swamped with agencies for things that would sell with a little pushing.

Unlimited agencies are a purely American invention which has entrapped many a careless firm. From a business point of view they are often disastrous. The other day one of our most solid and famous manufacturing firms—not of automobiles—conceded to one man the agency "for territory south of the equator" for a new line of manufacture.

Much Activity in and Around Boston

BOSTON, Apr. 2—In twelve weeks since the new Massachusetts automobile law, which includes a graded horsepower registration fee and an annual operator's license fee, has been in effect the receipts of the State from this source have been nearly equal to the total amount received during the year 1909. The receipts of the automobile department of the Highway Commission from January 1 to March 17 inclusive of this year were $166,681, while for the fiscal year of 1909 the total receipts were $169,973.54. For the corresponding 17 weeks from January 1 to March 17 of last year the receipts were $56,484.

So far there have been registered this year 13,058 cars against 9,100 for the corresponding period last year; 647 motorcycles against 403, and 488 manufacturers and dealers against 380. Original operators' licenses have been granted to 800 persons against 671, and 11,212 licenses have been renewed. Original chauffeurs' licenses have been granted to 493 persons, against 443, and renewed chauffeurs' licenses to 1165, against 851. As there were registered about 24,000 automobiles last year it is confidently expected that the income of the State from the automobile department this year will be considerably in excess of $300,000.

The recent automobile show and the good weather that has prevailed have stimulated the registration of cars, and the past week has been the busiest so far this year at the offices of the automobile department of the Highway Commission. Nearly 1200 cars were registered in six days and about an equal number of operator's licenses were issued. The influence of the show is seen in the registration of thirteen new dealers since the doors of Mechanics' Hall were closed.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

The old automobile will have to be brought out from its Winter hibernation, and, in order to obtain the best results from it, nothing remains but to give it the thorough overhauling it was promised last year. The temptation will be to trade it in for a new one, and the wisdom of choice will depend upon the condition of the car from a mechanical point of view and the state of the owner from a pecuniary standpoint. In any event, considering cost, it will be necessary to determine whether or not it will be less costly to purchase a new automobile than it will be to repair the old, and, in thus discriminating, good judgment must be fortified by keen perception.

If the car in hand is promising, and it should be unless it is several years of age, it should be held immune from the machinations of the novice who thinks big and does little; many an automobile has been ruined by just this class of the genus novice. The repairing of an automobile, if the work is properly done, is a prosaic undertaking, full of sad experiences, even to the man who is accustomed to this class of work, and it demands a fair display of horse sense, some skill as a mechanic, and the entire absence of anything like a desire to reform the plan of the maker.

The man who thinks he can build a better automobile than the one who may be responsible for the car that is to be repaired, should know better than to hamper his good ideas by planting them in an old automobile; they will shine better if they are contained in a positively new production, and the old automobile will not then be ruined in the undertaking.

System is everything in a repair job; it takes time to hunt for and find the parts after they are cast carelessly about, and it is even a question if the artisan will hunt for them after they are mislaid. Cleanliness is worth much, and after the parts are thoroughly cleaned they may be inspected for the purpose of determining their competence to render fit future service. It is something of an undertaking for a man of no experience to observe with certainty the value of a used part, and it may even be a job for an expert to ascertain if the structure has been rendered crystalline in service.

If the results of service do show on a part, and if the metal has "aged" up to the condition showing a crystalline structure, the best way, perhaps, is to purchase for use a new part. The crystalline structure may be corrected if the facilities for heat treating are available, provided the workman is sufficiently skilled in the art to know what to do.

♣ ♣ ♣ ♣

Large combinations are suspected of the people, but this attitude is not always justified. The automobile business has had an unusually rapid growth; so rapid, in fact, that there has been no semblance of competition, but, today, it is fast approaching a stage where production is so close to demand, that makers will soon come into competition one with the other. When that time comes, in the near future, as come it must, that manufacturer or group of manufacturers which is best fitted to get out good cars will get the full share of the business, while the makers with less complete or less able equipment will have to take what remains.

Equipment may mean in this connection, not alone factories, supplies on hand and connections which will yield further suitable supplies, but also men, both the men higher up and the workingmen. From the point of view of the buyer, or, as he is usually called, the ultimate consumer, such group of makers is far more satisfactory to do business with, not alone from the fact that the very size and bulk spell permanency, but also from the point of view of ability to supply the desired article, which a less well-equipped firm would not be able to furnish. These two ideas taken together mean satisfaction, first, for the immediate present, and, second, for the more or less remote future.

As to equipment, that factory is best equipped which possesses the largest number of new and suitable tools, which has the best shipping facilities, which has old and seasoned workmen tuned up to that company's class of work through many years of service, which is closest to its market, nearest or most closely connected to its source of supplies, and which is best equipped as to factory and selling organization. In a group of makers, allied for mutual advantage and betterment, it is possible to improve on some of these items, however well they may have been taken care of in the past. Thus, to cite an item, one can buy, not alone more cheaply, but also better in every other way, for 5,000 cars than for the much smaller number of 500. In this and other ways a group of makers in close touch can serve better than the same number of makers acting independently and competing somewhat with one another.

More News Jottings from Motor Center

DETROIT, MICH., Apr. 4—Among the most recent American concerns to invade the Canadian field is the Anhut Motor Car Company, of Detroit, which has purchased the Chatham Motor Car Company, of Chatham, Canada, and will devote the plant to the production of Anhut Six cars. The capital stock of the company has been increased from $150,000 to $300,000 to take care of this expansion.

The Stuart Commercial Car Company has been incorporated at Detroit, with a capital stock of $300,000, of which $65,000 has been paid in. The concern will manufacture power wagons.

There is no better indication of the growth of the automobile business than to watch the increasing output of drop forgings, and the effect this product is having upon the plants devoted to this class of work. The Anderson Forge & Machine Company, of Detroit, Mich., reports that it is now putting out 1,000,000 pounds of steel per month in the form of drop forgings, and that a new plant, which is now under way, will be complete and ready for occupancy by July 15.

The Detroit-Dearborn Motor Car Company has increased its capital stock from $50,000 to $100,000.

The Commercial Motor Car Company, of Detroit, has been incorporated with a capital stock of $30,000.

The capital stock of the Detroit Carriage Company has been increased from $50,000 to $100,000.

Wisconsin State Endurance Run Insured

THE Milwaukee Sentinel has donated a trophy, valued at nearly $1,000 as an award to the winner of a reliability or endurance run, open to Wisconsin owners and dealers. The prize will be held by the winner for a year and will be competed for annually. The winners' names will be inscribed on the cup.

George A. West, treasurer of the Wisconsin S. A. A. has been selected as chairman of the contest committee which will have charge of the annual event upon which the award will be based.

Plans for the run this year have not yet been completed, but it is certain that the tour will cover a large part of the State and may require from three to six days. A tentative plan formulated by President M. C. Moore of the W. S. A. A., contemplates a run of six days, extending from Milwaukee to Madison; Madison to La Crosse; La Crosse to Eau Claire; Eau Claire to Merrill; Merrill to Appleton and back to Milwaukee.

It is probable that the run will be made in July, although a definite date for it has not been set. Wisconsin motordom is highly interested in the event and inquiries from various parts of the State indicate that the entry list will be representative and likely to exceed in point of size anything of its kind ever given in the Northwest.

Coming Events in the Automobiling World

Apr. 6-9..........Watertown, N. Y., Automobile Show, Watertown Automobile Dealers' and Manufacturers' Association, in the State Armory.
Apr. 6-9..........Duluth, Minn., Armory, First Annual Duluth-Superior Automobile Show.
Apr. 7-9..........Kalamazoo, Mich., National Guard Armory, Automobile Show, Kalamazoo and Southern Michigan Automobile Dealers.
Apr. 9-16.........Elmira, N. Y., State Armory, Automobile Show, Elmira Chamber of Commerce.
Apr. 11-16........Harrisburg, Pa., Kelker Bldg., Automobile and Sportsman's Show, Harrisburg Automobile Dealers' Association. B. R. Johnson, Manager.
Apr. 11-16........Erie, Pa., Meyer Block, Automobile and Motorcycle Show.

May 2............Flag to Flag Endurance Contest, Denver, Col., to City of Mexico.
May 5-7..........Atlanta, Ga., Track Races. Atlanta Automobile Association.
May 9-11.........Harrisburg, Pa., Fourth Annual Reliability Contest to Atlantic City and Return.
May 21-22........Bay Ridge, L. I., Club's Endurance Contest Around Long Island, Crescent Athletic Club and Long Island Automobile Club.
May 30...........Bridgeport, Conn., Hill-Climb up Sport Hill, Automobile Club of Bridgeport.
June 11..........Wilkesbarre, Pa., Annual Hill-Climb up Giants' Despair, Wilkesbarre Automobile Club.
June.............Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, through the Southwest.
June.............Worcester, Mass., Hill-Climb up Dead Horse Hill, Worcester Automobile Club.

Foreign Shows and Races

Mar. 31-Apr. 8....French Spring Wheel Competition.
Apr. 2-24.........Turin, Italy, Automobile Show.
Apr. 27-28........Brooklands, England, Two-Day Meeting.
May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.
May 28-June 9....St. Petersburg, Russia, Automobile Exhibition.
May 29...........Copa Catalunya, Voiturette Race of the Royal Automobile Club of Spain, near Barcelona.
June 2-8..........Prince Henry (German) Touring Competition.
June 13-18........Scotland, Scottish Reliability Trials.
June 20...........French Voiturette Race.
June 21...........French Stock-Car Race.
June 22-July 5....Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.
June 27...........Speed Trials at Kiev, Russia.
July 12-18........Ostend, Belgium, Automobile Week.
July 20-25........Boulogne, France, Automobile Week.
Aug. 1-15.........Ardennes, France, Meeting.
Aug. 15-Sept. 15..French Industrial Vehicle Trials.
Aug. 21...........Salon, France, One and Five Kilometer Trials.
Aug. 28...........Mont Ventoux, France. Hill-Climb.

A.C.A. RULES FOR CERTIFIED MOTOR TESTS

DETAILED rules to govern certified tests under the jurisdiction of the Automobile Club of America have been formulated by the Technical Committee of which A. L. McMurtry is chairman. The rules have been framed to cover tests of the merits of motor vehicles generally and all their material accessories.

Special stress is laid upon the use of such tests as advertising and publicity matter by the entrants and a definite agreement is insisted upon by the club that the entrant shall accept the official record and agree to the publication of such by the Technical Committee and he is also required to submit proposed publicity and advertising matter based upon the club certificate to the committee, prior to publication.

The rules are as follows:

1—**Object:** The object of the tests is to determine the merits of a motor vehicle as a whole or in part, or an accessory, under various conditions.

2—**Certificates:** The Club will give a Certificate of the actual performance during the test and official representative or representatives are to be provided for the test, by the Committee. The certificate shall be a record of the test, containing such details of the motor vehicle or part thereof, under test, and any observations the Committee may find desirable. A copy of the results shall be published in the Club Journal.

3—**Interpretation of Rules:** The interpretation of these rules shall rest entirely with the Technical Committee which, may, from time to time, alter, add to, or omit from them, and may, in the case of any particular test, modify the rules to suit a particular case.

4—**Postponement:** No test shall be postponed or abandoned without the consent of the Committee, except that on the day of the test the Committee's representative or representatives may order a postponement on account of the weather, road conditions, illness, or contingencies beyond the control of the Committee.

5—**Time of Test:** Unless otherwise specified, a day's test shall consist of eight hours' duty, at the expiration of which time the motor vehicle shall be placed under lock and key and subject only to the inspection of the Committee. Time of starting the test shall be determined at least forty-eight hours previous to the start.

6—**Supervision:** The motor vehicle shall be under the supervision of the Committee, from the time at which it is presented for trial until released by the Committee.

7—**Extension of Test:** The entrant may, at any time before the completion of the test, give notice in writing to the Committee, that he wishes to extend the duration of the test, subject to the approval of the Committee.

8—**Adjustment and Repairs:** All manipulation, adjustment or repairs shall be carried out only by the entrant or his employees.

9—**Entries:** Every entrant shall state the nature of the test and the number of days to be occupied. The entrant shall, with the consent of the Committee, be entitled to alter the duration of the test on paying the additional fees. After receipt of the entry the entrant will be notified of the day fixed for the commencement of the test. The Committee reserves the right to refuse any entrant without giving a reason or to limit the length of any test at its discretion.

10—**Withdrawal:** The entrant may, at any time before completion of the test, give notice to the Committee that he wishes to withdraw from the test, and shall state his reason. In the event of such notification the motor vehicle shall remain under the supervision until the cause thereof has been investigated and the motor vehicle released by the Committee.

11—**Inspection:** The Committee shall notify the entrant when an inspection of the motor vehicle or parts thereof, under test, is to be made, so that the entrant may have a representative present during such inspection.

12—**Foul Practices:** The Committee shall stop immediately a test of a motor vehicle the entrant or employee of which shall be guilty of misbehavior or unfair practice in connection with the test.

13—**Advertising the Test:** The entrant agrees to accept the official records of the Committee and authorize the Committee to publish them in such manner as the Committee thinks fit. The entrant may publish only the full and complete certificate issued by the Club. In the event of his desiring to publish by way of advertisement or otherwise, any other matter relative to the test, he shall submit proof of such matter to the Committee before its publication and he undertakes not to publish any such matter until he has received the written authority of the Committee. In which case he may use the words "Published with the authority of The Automobile Club of America."

14—**Responsibility for Damages:** An entrant shall have no recourse against The Automobile Club of America, the technical committee of the Automobile Club of America or any of its officials, employees or representatives under any circumstances.

15—**Fees:** Fees for the test shall be determined by the Committee in accordance with the nature and duration of the sest, and under ordinary circumstances will not exceed $25 per day.

Application: Every application for a test shall be made upon an official application form of the Committee and shall state the nature of the test, the number of days to be occupied and the name of one member of the Club guaranteeing the account.

Certified Fuel Consumption Tests—Regulations

1—**Object:** These tests are to ascertain and record the fuel consumption of a car.

2—**Rules:** These tests will be held under the Rules for Certified trials.

3—**Certificate:** The Committee reserves the right to add to the Certificate a record of the run, or any other observations concerning the test. (Such as weight and make of car, horsepower of engine, bore and stroke, type of carbureter, i. e., automatic auxiliary air supply, hand-regulated air supply, mechanical fuel feed, etc., method of control of engine power and speed, including whether governed, controlled by accelerator pedal, variable valve lift, or by the independent throttling of one or more cylinders, gear ratio, type of body, wind area, make and size of tires, and average speed of car in miles per hour.)

4—**Running Time Per Day:** A day's Road Test shall not exceed 150 miles, except in the case of a continuous run exceeding twelve hours' duration.

5—**Passengers:** The full complement of passengers or equivalent ballast which shall not consist of spare parts, shall be carried throughout the test, and the total weight thereof shall amount to not less than 132 lbs. per passenger seat. The entrant shall be responsible for filling all the seats except in the case of the representatives of the Club. The representative or representatives shall have the choice of seats. No extra passenger shall be allowed to ride on the floor or step.

6—**Muffler:** An efficient muffler must be fitted, and is defined as follows: Apart from any question of back pressure, an efficient muffler is one which renders the separate impulses of the exhaust gases from an engine indistinguishable under all ordinary running conditions, at the distance of 30 feet from the side of the car in an open road and which is practically gas-tight everywhere except at the proper outlets.

7—**Postponement:** No test shall be postponed or abandoned without the consent of the Committee, except that on the day of the test the Committee's representative or representatives may order a postponement on account of the weather, road conditions, illness, or contingencies beyond the control of the Committee.

8—**Arrangements** must be made to fit any tank or other device which the Club may consider necessary.

9—**Nature and Quality of Fuel:** A sufficient quantity of fuel may be taken from the tank by the representative for such tests as the Club may consider necessary to ascertain its nature and quality.

10—**Speedometer and Odometer:** A reliable speedometer and odometer must be fixed to the car and checked for accuracy on the Club dynamometer.

11—**Makes of Tires:** The car must be fitted with the regular tire equipment as specified in the manufacturers' catalogue. If the tire equipment is optional the Committee will select the make of tire as fitted to the largest number of cars of that make and type.

12—**Tire Pressure:** The air pressure in the tires must not be greater than specified by the tire manufacturer.

Certified Tests of Motors

1—**Object:** The object of the test is to subject a motor to a test of comparatively short duration, representing the equivalent of a considerably longer period in ordinary use.

2—**Rules:** The tests will be held under the Rules for Certified Tests.

3—**Number of Cylinders:** These Regulations shall apply for any motor, irrespective of the number of cylinders.

4—**Fuel and Oil:** The fuel will be supplied by the Committee, the quantity and quality to be noted. Lubricating oil may be supplied by the entrant, the quality to be recorded.

5—**Temperature:** The temperature of the cooling water shall be recorded and the water supply must not be less than 120 degrees Fahrenheit.

6—**Certificate:** The certificate shall show the results of the following tests:

(a) The fuel consumption on the dynamometer.

(b) The output of the motor as specified by the entrant maintained for a period of two hours, or any multiple thereof (at the declared number of revolutions), obtained without interruption of the test.

(c) The minimum B.H.P. which can be obtained for 15 minutes below some limiting speed to be declared by the entrant.

(d) The B.H.P. which can be maintained for the same period at one-half the limiting speed declared by the entrant.

(e) If required by the entrant, the mximum B. H. P. at 5 or more different speeds between and inclusive of the B.H.P., determined at the declared maximum and minimum speeds. These results to be those obtained with no other carbureter regulation or variation than the adjustment of air supply.

(f) A record of all repairs and adjustments which may cause stoppage of the engine.

(g) Bore, stroke, offset of cylinders (if any), weight of motor, normal speed, maximum speed, ignition system and make of carbureter, and any other observations the Committee may find desirable.

ANNUAL ELECTION OF A.C.A. APRIL 12

The Automobile Club of America will hold its annual meeting and election of officers, April 12 at the clubhouse, 247 West Fifty-fourth street. The following candidates have been nominated: President, Henry Sanderson; first vice-president, John E. Borne; second vice-president, Robert Lee Morrell; third vice-president, Edward Shearson; treasurer, Finis E. Marshall; governors (to serve four years, from April, 1910), Dave H. Morris, Albert R. Shattuck and E. H. Gary. Governor (to serve in place of Cornelius Vanderbilt, resigned, until April, 1912), Alfred Ely; governor (to serve in place of Horace Porter, resigned, until April, 1913), George Moore Smith. Widespread interest has been aroused, and an unusually full attendance is expected.

THOMAS B. JEFFERY DIED SUDDENLY IN ITALY

THOMAS B. JEFFERY, president of Thomas B. Jeffery & Company, manufacturers of the Rambler, died suddenly at the Grand Hotel at Pompeii, Italy, Saturday night. Mr. Jeffery was touring Europe with his wife, having left Kenosha, Wis., January 21, planning to spend at least four months abroad for rest and pleasure.

He was born at Stoke, Devonshire, England, February 5, 1845, and came to America when eighteen years of age. He located at Chicago and entered his trade, that of making astronomical and other instruments of precision.

He was the maker of the patent office models of the railway velocipede and later manufactured that device. In 1878 he joined the late R. Phillip Gormully in the manufacture of the Rambler bicycle, under the firm style of Gormully & Jeffery until 1897, when the business was sold to the American Bicycle Company.

Prior to this sale, Mr. Jeffery had been experimenting with the automobile and about ten years ago he purchased the old Sterling bicycle plant at Kenosha and commenced the manufacture of the Rambler automobile. He was the inventor and patentee of the clincher pneumatic tire.

Mr. Jeffery was married to Miss Kate E. Wray, of Chicago, in 1874. Besides his widow, he leaves two daughters and two sons, the latter being Charles T. Jeffery, who will succeed his father as head of the company, and Harold W. Jeffery. Charles T. Jeffery has been manager of the concern for several years.

The remains of Mr. Jeffery will be shipped back to this country and interment will probably be at Kenosha.

Thomas B. Jeffery, Maker of Rambler Automobiles, Who Is Dead

RICH PRIZES FOR ATLANTA WINNERS

ATLANTA, GA., Apr. 4—The card of events is out for the Atlanta Speedway races which will be held May 5, 6 and 7 over the two-mile Atlanta track.

The list contains only two long races, both at 200 miles and both for trophies of an advertised value of $10,000.

One is the "Atlanta Speedway Trophy" and is for cars of 301 to 450 cubic inches displacement. The other is for the 451 to 600 class cars and is called the Atlanta Automobile Association trophy and has added prizes of $1,000 and $500.

The one mile time trials have been made better worth while than ever before, with $150 for the car making the best time, $500 for the car breaking the present track record and making the fastest time, and $150 for every other car breaking the present record. The only other novelty is an Australian pursuit race.

The program includes twenty contests ranging all the way from a single mile dash free-for-all; ten, twelve, twenty, forty, fifty and sixty mile races, to the 200 mile-events. About $6,000 in cash and eleven cups and medals will be distributed.

VANDERBILT CUP RACE OCTOBER 1

Preliminary announcement has been made of the sixth annual competition for the Vanderbilt Cup, which will take place on the Long Island Motor Parkway Saturday, October 1, starting at 9 o'clock a. m. The course will be the same as that used in 1909 and will be 12.64 miles, with four turns, all well banked. Twenty-two rounds will be made, the total mileage being 278.08. The race will be run rain or shine. In addition to the cup, there will be a purse of $2,000 and a bronze placque by Tiffany, awarded the winner. The entry fee is $500 a car.

W. W. WALLACE, ADVERTISING MAN, DEAD

W. W. Wallace, who has been advertising manager of the Berger Manufacturing Company of Canton, Ohio, for many years, died March 29.

SAVANNAH-JACKSONVILLE ROAD RUN

SAVANNAH, GA., Apr. 6.—Twenty-one of the twenty-two entrants in the Savannah-Jacksonville tour completed the run today, a distance of 98.1 miles. No serious accidents marred the sport. The roads were in excellent condition except for three miles south from Darien and at King's Ferry.

Mrs. L. W. Hazard drove her ten-horsepower Maxwell over the course with a perfect score. Besides Mrs. Hazard, those who secured perfect scores were as follows: J. L. Highsmith, Maxwell; Chris Jacobs, Hupmobile; H. B. Flanders, Buick; L. R. Akin, Buick; W. H. Towle, Maxwell; Darwin B. Hull, Buick; The Rev. Francis Alan Brown, Maxwell; Henry A. Brantley, Maxwell; W. C. Thompson, E-M-F; W. C. Adams, Maxwell; R. S. Brown, Cole; Robert Brockett, Maxwell; Harvey Grander, Lancia; Eugene Maner, Acme; N. G. Brown, Packard and A. W. Solomon, Stevens-Duryea.

ART POSTER FROM MAGNETO FIRM

Beautiful just describes the art poster which is now being distributed by the K-W Ignition Company, Cleveland. This poster is 14 1-2 inches wide by 35 inches high and a work of art.

The idea of the spirit of the K-W magneto is carried out by a beautiful female form which rises in vapory outline from the spark-plug cables connected to the magneto. The figure continually grows stronger until it stands out against a starlit sky in all its beauty of line and color, while the red flame which the magneto produces and which is shown jumping between the two forefingers casts a warm glow down on the face and rounded shoulders, the beauty of which is hard to describe.

SALE OF WINTON OFFICIALLY DENIED

The rumor generally circulated last week that the Winton Motor Carriage Company had been sold to the United States Motor Company is officially denied by Alexander Winton, president of the Winton company.

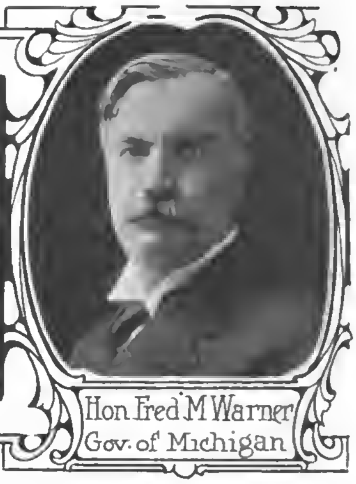
FIRST ANNUAL BANQUET



Hon Fred M Warner Gov. of Michigan

THE Hon. Fred M. Warner, governor of Michigan and the chief speaker on the list of those who will address the assembly, at the first annual dinner of the Association of Licensed Automobile Manufacturers, Thursday evening at 7 o'clock at the Hotel Astor, was a particularly happy and appropriate choice for that duty.

Governor Warner is the chief executive of the State in which over half of all the motor cars of the country are made. The industry in Michigan, is one of leading lines of endeavor of the citizens of that State. There are thirty-seven manufacturing plants devoted to the making of motor cars in Michigan. The annual product of the State is approximately 150,000 cars, valued at $190,000,000. In addition to this stupendous amount, over half of the accessory product of the country is utilized in the building of Michigan motor cars, thus adding the financial, economic and industrial potentiality of over 150 manufacturing establishments to the grand total.

Thus when Gov. Warner speaks about the automobile, his words will have a peculiar significance. The guest of honor traveled from Detroit in a private car and was received with formal ceremony as well as enthusiastic informal welcome.

The banquet hall of the Hotel Astor was magnificently decorated for the affair and a short time before the lists were closed, it was announced that practically the full number of guests expected, would be present, in all about 200. Acceptances of the invitations had been received from three-quarters of the members. Governor Warner is an optimistic conservative and his address is awaited by the manufacturers with something more than curiosity.

Job Hedges, the toastmaster, is one of the noted wits of New York and is a radical in his treatment of many interesting subjects, including the automobile. William H. Edwards, another of the speakers, head of the street cleaning department of the metropolis, is a forceful talker whose ideas have proved to be notably interesting. Col. Charles Clifton, president of the association is a careful speaker whose words carry much weight and influence and Arthur Brisbane, most widely known for his writing, is unusually brilliant in the field of oratory.

The banquet will undoubtedly become a regular feature of the activities of the A. L. A. M. In one sense such gatherings are diversions, despite the importance and vital interest of the topics discussed. They give the opportunity for social contact and acquaintance under favorable conditions. The tone of such a function as the first annual banquet of the A. L. A. M. is of the highest class, being almost formal and official in its character.

The membership of the association includes eighty-three of the leading motor car companies and under the plans of the committee in charge of the banquet arrangements, only three invitations were sent to each member. The object sought was to make the attendance representative of the whole association, to as large a degree as possible. This plan will have the effect of eliminating anything like a dominating influence, based upon a large local attendance.

The dinner itself has been planned upon the most complete lines of the celebrated hostelry where the function will be held. The menu will be especially elaborate, and all the details set in harmony with it.

The general trend of the addresses will be the past, present and future of the automobile and in that wide scope, the speakers will have an opportunity to touch upon a thousand and one subjects of direct moment to the industry.

Aside from the regular list of speakers there will be several impromptu addresses and discussion of the topics treated in the formal toasts.

The tendency toward centralization, which has been impressively shown by the trend of events recently, will undoubtedly receive a considerable amount of attention. The trade generally is much interested in the gathering on account of the representative character of the men who will be here, particularly in connection with the idea of the reported mergers and rumors of mergers in the industry.

A.A.A. GIVES OUT 1910 GLIDDEN RULES

(Continued from page 672.)

438—A seal broken in the day will be replaced the evening of that day at the garage by the promoter's technical committee.

439—Breaking Seal—There will be no penalty for breaking a seal.

440—Lubrication—At the completion of each day's run—except the final day—after the cars are garaged, ½ hour will be given each contestant for lubricating all parts of the car, such as crankcases, filling and turning of grease cups, motor, transmissions and other parts. This will be done under the supervision of the observer and a member of the promoter's technical or contest committee. Seals will be broken to permit of properly lubricating the car during this half hour.

DRIVERS

441—Drivers may be changed as often as desired, but report of same is required to be made to the referee and the regular and substitute drivers shall be named in the entry blank. In case of illness, emergency drivers may be used. Drivers shall report at the official garage or park ½ hour before the announced starting time for the day and they, together with the observers, will be placed in charge of cars, whereupon they will immediately proceed to the starting line and take their proper places ready for the start. Drivers must not rely upon information obtained from the observers as to the route to be followed or as to any question regarding penalties.

OFFICIAL HEADQUARTERS

442—There shall be an official headquarters where all announcements shall be posted on a bulletin board before and after a contest.

443—Before the start of any contest, all drivers, observers and entrants shall attend a meeting held for the purpose of instruction as to the intent of these rules. This meeting shall be in charge of the referee.

444—When the contest exceeds one day in duration an official bulletin board shall be displayed at a known headquarters each night, giving such additional information as may be required. Failure on the part of drivers, observers or entrants to attend the meeting of instruction and to consult the official bulletin board displayed at the headquarters shall be at their risk.

START

445—The time of starting shall be announced by posting on the bulletin board, or otherwise, the evening previous to each day's start. Cars will be started each morning at the hour announced the evening previous, the different cars starting at one minute intervals.

446—Cars shall start in the order of their presentation at the starting line and without regard to classes or divisions.

OFFICIAL NUMBERS

447—Each car shall have its official number prominently displayed on each side of the hood, painted on the radiator in front, and if possible, on the rear of body.

448—The name of the car in letters 4 inches high may appear upon the sides and upon the front and rear.

PACEMAKER

449—Each day's contest shall be preceded by a pacemaker; and by any entrant or representative thereof who passes the pacemaker shall be disqualified. The referee shall go with the tour in the pacemaker's car in order that he may be accessible to contestants at the end of each day's run. If the pacemaker's car breaks down or is compelled to travel at a rate of speed so slow as to impede the progress of the tour, his flag shall be transferred to the first suitable car overtaking him, which car shall thereafter become the pacemaker's car, subject to the same conditions, until such time as the official pacemaking car can again perform the duties.

CLASS A AND DIVISIONS

Competing cars shall be divided into the seven divisions of class A, as follows: Rule 400.

Division 1A	$ 800	and	under
Division 2A	801	to	$1,200
Division 3A	1,201	to	1,600
Division 4A	1,601	to	2,000
Division 5A	2,001	to	3,000
Division 6A	3,001	to	4,000
Division 7A	4,001	and	over

DAILY RUNNING TIME

450—The following average speeds shall be maintained by the cars in the respective divisions of class A:

Divisions 4, 5, 6 and 7	20 miles per hour
Divisions 2 and 3	18 miles per hour
Division 1	16 miles per hour

451—All cars to avoid penalty will arrive at checking stations as per their schedule, plus additions, if any, to the running time for delays on account of tire troubles. Rule 420.

452—The referee may, if the necessities of the weather or road conditions demand, vary the speed schedules, announcement of any change being made by the starter previous to the start of the day's run to which the change shall apply, or during a day's run at any checking station by the checker at the designated station where the change is made, due notice being given to all contestants who shall acknowledge receipt of such notice by signing the checker's card.

CONTROLS

453—The official station established at the end of each day's run where the cars are officially checked, shall be known as the night control. The official stop for luncheon on each day's run—if there be one—where cars are checked in and out shall be known as the noon control.

454—Each contestant shall be ready each morning to check out at the time announced. Checkers shall be at their stations at that time prepared to start the cars. The time of departure each day shall be entered on the observer's card.

455—Each entrant, or official representative of such entrant, upon starting each day's run, shall sign a statement submitted by an official of the contest fixing the time of his departure, and shall be given a card indicating such time, which card shall bear the signature of said official. Failure to comply shall result in disqualification.

456—Controls and checking stations will be indicated by a flag with a white field and diagonal bar of red.

457—The referee may establish such checking points as he may deem proper. Each car shall be checked upon passing the established checking points and if ahead of time at the noon or night controls may immediately check in.

458—No car will be checked either in or out without its observer.

459—There shall be established at the close of each day's run a parking station, in which all competing cars shall be stored. The station shall be in charge of an official representative of the promoter's technical committee.

460—No work may be done on the cars while in the official garage or parking station, except lubrication during the half-hour allowed at the end of each day's run. See Rule 404.

461—Following the registration at each night control, each car shall be delivered into the custody of the officials of the tour at the official garage or parking station to be by them held at the owner's risk, and kept under direct charge and supervision of such officials or their agents until the time for starting on the following morning. Immediately after registration at night controls and before delivery to the official garage or parking station, the car may deliver the occupants—other than the driver and observer—and baggage at hotel and then must immediately proceed to the parking station. The observer must not leave the car until it is parked.

462—Passengers and baggage may be taken on at the parking station after the car has been delivered to the driver and observer but before checking out in the morning, or at the hotel after checking out when no time shall be allowed.

INTERMEDIATE CHECKING

463—Checking stations shall be established in so far as may be necessary to stop speeding. Each driver shall receive a card when checking out in the morning which shall name the checking stations and the time the car is due at each station, so that he may estimate his running time during the entire day. There shall be no appeal from the time registered by the official watches; drivers and observers shall be required to rectify their watches each morning with the official time.

464—Cars cannot check in ahead of time, except at the noon and night controls.

OBSERVERS

465—Each entrant shall furnish at his own expense one official observer for each car entered by him. All observers shall be acceptable to and subject to the instructions of the promoter.

466—The entrant must arrange for the care and keep of his drivers and observers and pay any expenses connected therewith. He must also carry during the contest the baggage of each observer furnished by him.

467—If the entrant is a motor car manufacturer or dealer, or in any way connected with the manufacture or sale of motor cars, each observer furnished by him shall be:

A—A person who has been regularly and exclusively employed by the entrant by whom he is nominated for a period of not less than 3 months immediately prior to the contest, or

B—The entrant himself or an officer or director of his business, or

C—A dealer in the car made by the entrant, or

D—As owner of a car by the entrant.

468—If the entrant is not a motor car manufacturer or dealer, the observer furnished by him shall be satisfactory to the promoter.

469—Each observer shall be assigned to a car and shall ride each day in a different car and no person shall serve as an observer on any car in which he has any direct or indirect pecuniary interest.

470—Observers shall report each morning at the official garage or park ½ hour before the announced starting time for the day, and take charge of the cars to which they have been assigned.

471—Each observer will be responsible for the tools of each car, as per rule 417.

472—Each observer must note the length of time in minutes and fractions of each stop made; if the motor is stopped or if any work is done, and also record what work was done on the car during the stop, how many persons were working, tools used and how long each person was working. See rules 485 and 521.

473—In case of breaking a seal, the observer will note the seal broken and must report how many times thereafter access was had to the part or parts protected by the said seal.

474—The observer must see that the running car is stamped or marked by the checker at each control or checking station and that his car does not pass a control or checking station before the time marked upon the running card, except at the noon and night controls, and also that the route is followed.

475—The referee shall be empowered to suspend any observer who neglects, is incompetent, or for any other reason fails to fulfill the duties assigned to him, and to provide a suitable substitute at the expense of the entrant by whom the suspended observer was nominated.

476—It shall be the duty of each observer under all conditions and without evasion of this rule for any reason whatsoever to remain with the car until he has been relieved by the chief observer or obtained the driver's signature to a statement that he has withdrawn from the contest and to report every detail of the performance of the car to which he is assigned, and all persons who operate, repair, assist or perform any action connected therewith.

477—If an official observer shall desert a disabled car without first obtaining the driver's signature to a statement that he has withdrawn from the contest, the entrant who appointed such observer shall be disqualified and must either withdraw from the contest altogether or continue as a noncontestant. By desertion is meant leaving the car without taking with him the driver and passengers. This rule will disqualify but one of the cars of an entrant in case of multiplicity of entries.

478—In addition to the surveillance of the cars in which they are riding, observers shall be required in so far as possible to make note of any other car which may be laid up alongside the road and whether the work being done upon it appears to be done on the tires or on the machinery and on what part af the car.

479—At the end of the day's run, the observer must remain with the car throughout the half hour allowed the driver in which to oil his car, rule 440, and when this is done, leave the car at the same time and in company with the driver—and deliver to the chairman of the technical committee or his delegated representative the running card, after obtaining the signature of the driver upon said card and signing same himself. The driver shall in no case be permitted to return to a car without the observer.

480—Should any objection be made by the driver to the record, a report may be immediately made to the chief observer and by him it may be referred if necessary to the referee for settlement. In the event of a dispute as to facts the referee may require the driver to state his objection in writing. The record may also be inspected by any other properly authorized representative of the entrant, who shall also have a right to register an objection and submit proof in support thereof.

481—At a checking station, or at any regular stop, should the observer wish to leave the car he must not do so until relieved by some official of the contest, who, at the same time, must appoint a relief observer, who shall remain with the said car until the regular observer returns to it. After he returns to the car, the regular observer must receive a report, orally or otherwise, from the relief observer as to whether anything was done on the car during his absence.

482—Observers must not interpret rules for entrants or drivers and cannot say what work may or may not be done without danger of penalization, their duties being solely to record what is done and the exact length of time consumed in doing it.

483—In case of a tire repair when the engine is running the observer shall sign and hand to the driver a printed form on which is filled in the time consumed and see that the time is added to the running time, as provided for in rule 420.

484—In the event of sickness or an accident to an observer, which shall make it an impossibility for him to remain with the car, or secure a substitute properly authorized, he shall select one of the passengers of the car as a substitute observer, who shall perform all of the duties pertaining to the position, and shall, in addition thereto, have his record signed by all the occupants of the car during the time he is on duty.

485—When any work whether under penalty or non-penalty conditions is being done on different parts of the car, making it impossible for the observer to properly watch each operation, the observer may compel one of the workmen to stop until such time as he can properly watch him.

ROAD REGULATIONS

486—Entrants and official representatives of entrants shall conform to all laws, ordinances and rules of the road, and any entrant or official representative of such entrant violating any of the provisions of these rules, or who shall fail to show due consideration to the officials or other participants in the tour, or other users of the highways, may be disqualified or penalized, at the discretion of the referee.

487—Any car whose owner or driver shall be arrested for a violation of speed laws, or of any law or ordinance, may be disqualified or penalized, at the discretion of the referee.

488—When road conditions are so bad that a car cannot get sufficient traction to move, or is ditched, and reasonable effort has been made to extricate it, towing or other external means may be used to relieve the immediate distress only, but under no circumstances shall a car enter a night or any other control except under its own power. During such work of extrication the passengers need not necessarily remain in the car and may assist in the work. When towing or assistance from any external source shall have been received by a car its observer shall make a full and complete report to the referee, giving time, place, conditions, distance of tow and any other details. The sense of this rule is not to permit the towing of a car for any considerable distance.

489—All replacements, adjustments and repairs shall be done only during the daily running time.

490—The pacemaking car shall precede the contestants not less than 15 minutes ahead of the first car and with instructions not to exceed the running time of division 7 between any two checking stations. Where local conditions are factors, modifications of this rule may be made by the referee, due notice of same being given to contestants.

491—Contesting cars must not pass the pacemaking car unless it is running behind its schedule. Should a contesting car pass the pacemaking car it takes the pacemaker and his flag and must set a pace not in advance of that which the pacemaking car should have set.

492—Should the contesting car fail to maintain the proper pacemaking pace, it must surrender the pacemaker's flag to the next car that is suitable to take up the pace.

493—The pacemaker's flag shall be a navy blue field.

494—Cars unintentionally leaving the course must return to it at the point whence they left, under penalty of disqualification.

495—Cars intentionally leaving the course to make repairs may be disqualified, at the discretion of the referee.

NON-PENALTY ALLOWANCES

496—At noon or night controls, tanks for lubricating oil, gasoline and water may be filled without penalty.

497—For replenishments of oil, gasoline or water at any other places the penalty is 3 points for each occurrence.

498—Oil or grease may be added to or may be drawn off the various cases when necessary without penalty during the half hour allowed for oiling at the end of each day's run. Rule 440.

499—Recharging of batteries will be allowed at any time, but all work in connection therewith must be done in the presence of the observer.

499A—Brakes may be adjusted without penalty at Memphis, Tenn., and St. Joseph, Mo., under official observation.

499B—Carbureters may be adjusted for air or gasoline at night controls during ½ hour.

499C—Spark plugs may be charged without penalty at night controls during ½ hour allowed for oiling.

TIRES

See rules 419 and 420.

PROTESTS AND DISQUALIFICATION

500—A written protest may be filed with the referee by any participant in the tour, but must be accompanied by the sum of $25. If the protest is not sustained, this sum will be forfeited to the contest board; but if the protest is sustained the protest fee will be reurned to the person making such deposit. No protest not conforming to the above requirements will be considered. Each protest will be acted upon at the earliest practicable moment.

A—Any protests as to unfair rulings, foul driving, routes, etc., shall be made within 12 hours after the occurrence.

B—Any other protests may be made during the tour or within 24 hours after the tour is concluded and before any award is made.

501—No entrant or his official representative shall be disqualified until he shall have been notified of the act complained of, and if the act be denied, he shall be given a hearing, after which a decision shall be rendered. Upon notice of disqualification, the referee may compel him to cease to run in the contest and in that event the official numbers shall be removed from his car, and such entrant shall not receive any certificate, but shall be mentioned in the records as having been disqualified, and no entrant of any car that may be disqualified shall have any claim of any kind or nature whatsoever against the promoter or against the American Automobile Association or any members of any committee or any official of the contest, because of such disqualification, or the publication thereof, or failure to mention the performance of the disqualified car prior to its disqualification.

FINAL OUTDOOR OPERATIVE TESTS

502—The following tests are imperative at the completion of the contest in grades 1 and 2:

503—Brake Test—The car under test approaches a line across the roadway at its competing speed in the contest, one set of brakes is applied and the distance measured in which the car comes to a stop. The other set of brakes are similarly tested.

A perfect brake stops the car in 50 feet or under; a penalty of one point per foot or fraction thereof is imposed for distances above 50 feet.

504—Clutch Test—The front wheels of the car are rested against a vertical 8-inch curb, the low gear is engaged and the clutch let in. Failure to spin rear wheels, stall the motor or climb curb would be a bad clutch, for which a penalty of 5 points is imposed.

505—Transmission Test—Car must be driven on all different forward speeds and reverse. Failure to drive on any one speed incurs a penalty of 25 points.

506—Motor Tests—A—Gasoline cars, driving with open and closed throttle and advanced and normal spark to test firing. Penalty of 5 points is imposed for each cylinder not firing.

B—Steam Cars—Test to see if motor runs with open and closed throttle; if valve slide action is operative; if running temperature and pressure of steam are possible; if engine simples or compounds; and note if various gauges and controls are operating properly. Penalizations are per penalty schedule.

507—Penalization of Accessories—Speedometers, odometers, lamps, horn, clocks, storm fronts, tops and other accessories shall, at the option of the promoter, be penalized for work done upon them and for breaks and lost parts at final examination, which penalties will not count against the car, but against the accessories carried.

PENALTIES

508—All cars shall start with a clean score.

Any car which for any reason discontinues as a contestant shall be penalized 1,000 points in addition to all previous penalizations.

509—Time—At all controls or checking stations a car is given a 3-minute leeway. If due at a station at 10 o'clock, it has until 10.03 to arrive. The head checker must call aloud, or otherwise announce the time, that waiting contestants can check through during their proper 3-minute leeway.

510—Cars cannot check in ahead of the time marked on the running card, except at the noon and night controls, under penalty of disqualification.

511—After the expiration of the 3-minute leeway, each arrival shall be penalized 1 point for each minute or fraction thereof. See Rule 451.

512—Work—In penalizing for work done on a car, by its driver or passengers, a penalty of one point per man per minute, or fraction thereof, shall be imposed.

513—Penalty for Outside Work—Where work is done on a car by anyone other than the driver or passengers, the penalty will be 2 points per man per minute, or fraction thereof, for each of such outside persons.

514—Work in Running Time—Work must not be done on a car between the time it leaves the official garage and crosses the starting line and between the time it crosses the finishing line and enters the garage at the end of the day's run.

515—Replacement—A—Where a replacement is made by the driver or passengers, the penalization is 2 points per man per minute or fraction thereof.

B—Where a replacement is made by workmen other than the driver or passengers, the penalization is 4 points per man per minute or fraction thereof.

FINAL EXAMINATION PENALTY

516—At the close of the contest, each competing car, after being properly washed, shall be delivered to the technical committee, who shall record all adjustments, replacements or repairs necessary to place in car in a safe and satisfactory condition, and penalties therefor shall be imposed in accordance with the fixed penalty schedule as given in detail in "The Automobile" for March 24, 1910. In this list of penalties, the following heads were used under which the penalties were prescribed for many specific accidents: Lubrication, carburetion, brakes, running gear, cooling, ignition, steering, machinery parts, and steam. These penalties vary from 1 point upward to 500, which is the provision for a broken frame side member, a broken cam, or a broken crankshaft.

Parts of cars not enumerated in the schedule, which are discovered to be faulty, impaired, lost or loose, shall be penalized in due proportion to those therein enumerated.

517—Front and Rear Axles—No penalty shall be imposed when the spread between the two front or two rear wheels, measured at the ground, is ¼ inch or less. When the spread exceeds ¼ inch, the penalty shall be 5 points for each ⅛ inch or fraction thereof.

518—Springs—A sag of 1 inch is permitted without penalty. For each additional ⅛ inch or fraction thereof, 5 points.

519—Motor Stops—Motors may be stopped at controls and while gasoline is being taken on. Other stoppages of motors between the starting and finishing of each day's run will result in a penalty of 1 point per minute or fraction thereof for time stopped when no work is done on car.

No penalty, however, shall be charged for a motor stop during the time occupied by a replacement or work on a car for which replacement or work a penalty is imposed.

520—The use by a contestant of any part which may be carried by any other car accompanying the tour as a contestant or otherwise, or which constitutes a part of its make-up or equipment, shall cause the disqualification of the car.

521—In recording time to be penalized, the operator of the car and the observer must mutually agree as to the time when work commences, which shall be immediately recorded on the observer's card, and as to the time when such work ceases, which shall also be likewise immediately recorded.

NON-CONTESTANTS

522—Non-contesting cars must wear a sign or banner, approved by the promoter, bearing the words non-contestant, in letters 4 inches high on the sides and front, and such cars shall be subject to all road rules and regulations of the contest.

523—A car having withdrawn from the contest will be permitted to continue the run, but without the official numbers, and all banners and numbers must be surrendered to the promoter as soon as the car be withdrawn and the words non-contestant displayed as provided in rule 522.

AWARDS

524—At the close of the contest and after receipt of the report from the technical committee of their final examination, the referee shall post on the bulletin board at official headquarters, rule 430, his decisions as to the awards.

528—Summary of Penalties—Time—1 point per minute, or fraction thereof, late in arrival at any control or checking station.

Work—1 point per man per minute, or fraction thereof, for labor by driver or passengers.

2 points per man per minute, or fraction thereof, for labor by workmen other than driver or passengers.

2 points per man per minute, or fraction thereof, for replacement of damaged parts by driver or passengers.

4 points per man per minute, or fraction thereof, for replacement by workmen other than driver or passengers.

3 points per occurrence for replenishing gasoline, oil or water, outside of fuel controls.

Motor Stops—1 point per minute, or fraction thereof, for motor stop when no work is done. No penalty for motor stop during period when work is being done on car, for which work or replacement a penalty is imposed. See rule **519.**

POWERS OF BOARD COMMITTEE

1. The committee of the contest board shall manage the tour, with full power to enforce the rules, render decisions and do anything else that would be within the province of the contest board of the American Automobile Association.
2. The committee or its representatives shall have power at all times to make such examinations of the cars and their contents as may be deemed advisable.
3. The committee shall have power to disqualify any car for traveling at any speed which it may consider excessive under the conditions existing at the time, and without reference to these rules.

GENERAL

Entrants, drivers and observers shall consult the bulletin board at headquarters each night for additional information; failure to do so will be at their risk. All points not covered directly with these rules will be subject to the general 1910 contest rules.

HOTEL ACCOMMODATIONS

Hotel arrangements will be under the management of competent hotel men who have had large experiences in rooming guests at conventions and other gatherings. These men will take complete charge of the rooming at each night's stop. The committee particularly requests that no individual hotel reservations be made in advance. No preference will be shown in selection of rooms.

BAGGAGE

Each contestant must take care of and handle such baggage as he and his guests may need.

Columbia Plant Was Merged

(Continued from page 667)

The factory is of a peculiar layout, with a large office building, two stories high, and having a large basement, while the main part of the factory proper is three stories high with a high basement making it practically four stories high. This part of the plant has a peculiar shape, consisting of two ells, one of which has the office structure for a top, while the other ell branches out from the side of this, the long part of the latter being by far the longest building of the whole plant, and exceeding 500 feet in length. In addition, an equally long structure of but one-story height, houses part of the immense drop forge shop, the blacksmith shop, the battery rooms, the tin shop, and at the extreme rear, a very large repair shop, where the testers also make their headquarters. All around the rear of the buildings, there is ample space to grow, in unoccupied land the property of the company, while in the front, the power house is located within an angle of the main high buildings. Taken as a whole, the available floor space covers no less than 350,000 square feet, while the land now owned would allow of an addition of an equal amount without crowding or increasing the height of the present buildings.

As to shipping facilities, the factory is served by the railroads through the medium of the company's own siding, well located along the side of the building in which the raw stock is stored as well as that in which the chassis are finished and in which they receive the finishing touches.

In these buildings, not in their present guise however, Columbia cars have been built for the past sixteen years, or since 1895. It is true, that the product did not always have the worth it possesses at present, but viewed from the state of the industry at that time, it doubless was fully as good then as it is considered to be to-day.

Moreover, most of the mechanics who worked on the first Columbia cars of sixteen years ago are still working upon Columbia cars, for the employees of this firm have been well cared for, and have stayed with the firm through many vicissitudes. So, it is not strange in passing through the shop with some officer of the firm to hear that "this man has been with us fifteen years, that man has been here sixteen years, over there is a man who came with us fourteen years ago, etc."

Machine tools are not all new, but those which are too old to lend themselves well to the modern highspeed work are now being removed and replaced by more up-to-date tools, which have been purchased. These additions will bring the plant right up to the minute, and place it in a position to turn out the balance of the projected 800 cars for 1910 in rapid fire order. Following that, the work on 1911 cars will be begun, the present plans including 2,000 of the popular and swift-selling Model 48, and in addition, 1,000 electrics, principally victorias.

Notable among the present tool equipment is the drop forging outfit, which in all fairness is not outranked by any similar outfit in the automobile business to-day. Not alone are there numerous drop forge hammers, but the stock of dies for this work covering many years experience with it, is most full and complete. Camshafts, crankshafts, hubs, all levers, all rod ends, gear blanks, jig and tool blanks, fender irons, body irons, dumb irons for the springs, spring seats, valves, connecting rods, axles; all these and many more are turned out in this most complete shop. In addition to the large number of drop hammers, there are many bulldozers, hand forges, small, and large trip hammers for working over steel required to be of a high quality, while the hardening and tempering outfit is such as to complement the forge equipment. Fully as valuable to the firm as the tools, space they occupy, dies, and small tools to go with them, are the men to operate the machines, the latter all of them old hands. Now-a-days, good hammersmen are very scarce, so much so that men of this calibre are really prizes which farseeing firms keep close and jealous watch upon. In this respect, the Columbia works is well fixed.

Body building and trimming work for automobiles has become a fine art, and in this, no less than in other departments, the plant at Hartford is fitted out with the best. The body department occupies a full floor of the longest building, where the natty runabouts, stately enclosed bodies, and more usual touring cars are turned out in quantities, but with all the care possible.

At the rear end of the ground floor is located the very large repair shop, from which the testers work also. In this room all repairs are made on old cars brought back for renewal, while the aforementioned testers do their work of taking up bearings and such other little things as the outside test—which is always strenuous—has brought to their notice. In the matter of final testing of the complete chassis the company is peculiarly fortunate in its location, this being on the outskirts of the town, so that the main road alongside of the works may be used without giving trouble. This gives room for a test of many miles of diversified testing, which would not be possible on a limited track.

ACCOUNT OF REPAIR OF AN OLD CAR

(*Continued from page* 661)

The peining process consists of holding the rings on an anvil, or other suitable shape, and with a pein hammer, strike a series of sharp but light taps against the inner surfaces of the rings at equidistant points around the inner periphery, thus gently but persistently forcing the lay of the metal in the rings into the shape which will render it persistent and of the new desired diameter. The rings must be poised on the edge of the anvil in such a way that the metal will tend to flow in the direction which will afford the new and larger diameter, but they will be broken if in the process the novice strikes too hard a blow, landing the face of the pein hammer at too great a distance from the point of support.

An examination of the pistons in the figure will show that they are considerably worn at diametrically opposite surfaces as at P1, and show no wear at all at points 90 degrees around from the worn areas, as at P2. This is evidence of deformation of the pistons, due, no doubt, to an inadequacy of design, and contrary to the usual expectation the surfaces of greatest wear are 90 degrees remote from the surfaces of maximum pressure. This is a point which has never before been brought out, and it would seem that when the pressure comes on the pistons buckle, tending to form an ellipse, which formation is restrained due to contact with the cylinder walls, but the pressure thus exerted over a relatively small area of the total piston surface produces the undue wear as indicated in the illustration.

The connecting rods seem to be of sufficient strength for their intended purpose, but the brasses at the crankpin end show wear in such a way as to indicate that there was a considerable amount of side pressure due, no doubt, to absence of perfect alignment and a lack of proper endshake. Going back to the illustration, it will be observed that the least wear came at B1 and B3 of the brasses, and the greatest wear at B2 and B4. It will also be observed that the liners which separate the large end from the cap were not at all uniform in thickness, and in one of the connecting rods there were no liners at all. This state of affairs seems to indicate either a lack of uniformity in the assembling process, or a considerable amount of wear on a basis which was anything but uniform, as between the respective journals.

TIGHT COMPRESSION NOT READILY REALIZED

The very fact that the pistons show wear over two diametrically opposite zones and no wear on the surfaces, which are 90 degrees remote from the surfaces of greatest depreciation, indicates that the bores of the cylinders are not round, and it is scarcely to be supposed that the packing rings, no matter how well they may be fitted, will serve well their intended purpose under such conditions. If the motor is to deliver even a fair proportion of power, considering its original ability, it will be necessary to rebore the cylinders to make them round, or, what is better yet, they may be ground to a new and true bore.

The blackened zones which show over the piston surfaces, presents evidence of the lack of ability of the rings to maintain tight compression, and, if a proper repair is to be made, it is necessary to not only make the bore of the cylinders round by grinding or otherwise, and then, in view of the now larger diameter, it will be proper to substitute new pistons for the old.

SUMMARY OF REPLACEMENTS INDICATED

In a motor of this size, considering the character of the service it is designed to render, the piston clearance at the top of the stroke should be 0.015 of an inch. This allowance will be sufficient to take care of piston expansion due to heat and assure good lubrication. Were the clearance to be much greater the pistons would slap against the walls of the cylinders and a very annoying noise would result. With the new pistons new packing rings would come as a matter of course, and, for a proper repair, under the circumstances, it looks as if the motor should have been benefited by the substitution of new parts as follows:

(A) New pistons machined to the new diameter to compensate for re-boring of the cylinders to make them round.

(B) New piston rings.

On account of the wear of the cams and the battered condition of the tappets, it is more than likely that it would have been worth while to add:

(C) New camshafts.

(D) New lifts.

(E) New supplementary springs for the lifts.

(F) New brasses for the camshafts.

A close examination of the brasses for the camshafts indicated that the repairman who made the overhauling last year was lacking in skill, and in fitting the camshaft brasses he carelessly filed them down so that they will scarcely serve well for the purpose, although the repair, as it is now completed, is very good indeed; the present work is being done by an expert in this line, and by the proper use of liners, after the brasses were properly shaped up, good alignment was realized, and there is a fair chance that it will remain so for a reasonable length of time.

CRANKSHAFT REQUIRES SOME EXPERT ATTENTION

The condition of the crankpin brasses is a sign of uneven wear of the crankpins, and, if the future performance is to be as good as ever, it is necessary to remove and regrind the crankshaft in order to make the pins round. That they are now elliptical is one of the points that a micrometer will very quickly settle, and that brasses will render good service when they are fitted to elliptical pins is a settled impossibility.

Each effort, when it is directed to the more complete repair of a car, adds responsibility; were the crankshaft reground the diameters of the pins would be reduced, and the brasses might have to be re-babbited. It is possible that 0.010 of an inch off the pins would bring them to round. This reduction would have to be compensated for by reducing the thickness of the liners an equal amount, and since the brasses would have to be re-scraped, they would be reduced in radial thickness at least 0.015 of an inch. This does not sound like a very considerable amount, but it is an important difference, and if it is not to be had nothing remains but to reline the brasses in order to realize it.

There are risks to take in a matter of this sort; if the crankshaft is reground, the strength of the same will be much reduced. Considering the fact that the strength of a crankshaft is proportional to the cube of the diameter, a very slight reduction in diameter has a marked influence on the ultimate strength of the same.

In a new shaft this reduction of diameter is a serious matter, but in an old shaft it amounts to a positive risk, it is well understood that the life of every crankshaft is limited; it depreciates in service; the kinetic ability of the metal reduces as sure as kinetic work is done, and, the older the automobile, that is to say, the greater the length of service rendered, the greater will be the chances of crankshaft failure, after the crankpins are reground to make them round and true.

It might be said, why regrind the pins if the danger is so great? The answer is, why repair the motor if the brasses are likely to melt out when the motor is put back to work. Certainly the chances of bearing trouble will be very great if the brasses are clamped up against elliptic pins.

How can the crankshaft be conserved after it is reduced in strength by the grinding process, which is utilized to bring the pins back to round? Let us examine the law and find out. Secondary moments increase as the square of the velocity. The answer is, reduce the velocity in the ratio, which will limit the extreme fiber strain to a safe point in view of the fact that the extreme fiber strain increases inversely as the cube of the diameter.

Since secondary moments increase as the velocity squared, it follows that any method which will limit the speed of the motor will serve as the remedy. A governor, for illustration, answers every requirement. By adding more teeth to the driving sprockets, leaving the number of teeth in the driven sprockets as before, the speed of the crankshaft considering the speed of the automobile on the road, will be lowered, and, a governor, if it is so adjusted that the motor will not speed up when the clutch is removed, will afford all the protection that the occasion requires.

In view of what has been said, if the truth is reflected, an unskilled repair man is in a position to play "hob" with an automobile, and the cost of the play falls upon the owner of the car. In a matter of this sort skilled workmen will do as much or more damage than will follow the efforts of unskilled men. Accentuated skill on the part of the artisan is bound to lead to greater activity and the extra effort, if it is in the direction of the reduction in diameter of the crankshaft in the absence of some method of compensation, will serve as the prelude to a broken crankshaft.

SUMMARY OF CONCLUSION FOR THE CASE IN POINT

Considering the automobile, which is taken as the example in this instance, a summary of conclusions are as follows:

(A) The crankshaft should be centered in a grinding machine and all the pins should be ground round and true.

(B) Since the linings of the brasses are worn down, and the shims are in bad shape, to reline the brasses would be proper. The new shims would then be of even thickness, with takeup available for the future, and, after scraping in, the bearings would then be in as good order as when the automobile was new.

(C) This would leave the crankshaft in a precarious state considering a high rotative speed, and in order to correct this evil it would be proper to apply a governor to the carbureter in order to limit the maximum possible speed after declutching.

(D) On account of the unbalanced condition of the clutch (a construction fault which was mentioned), it would be an advantage to add teeth to the driving sprockets in order to limit the speed of the motor when it is running the automobile on a hard level roadbed, and the steadying effect of the extra load thus imposed, while it would tend to load the motor more than before, would be advantageous because it would limit the speed of the same and minimize the kinetic strains.

(E) By setting the governor for a certain safe speed, the motor would be limited in its ability, and the speed of the automobile on a hard level road would then be kept down to a safe point independent of the ability of the motor from the abstract power point of view.

(F) The noted state of the sprocket wheels and chains is such as to call for a new set, and, as before stated, it would be the height of a fallacy to put a new set of chains upon the old sprockets.

(G) In view of the manner in which the side frame was repaired, and the fact that there is no lateral bracing just where the winding effect of the motor is most pronounced, it would be an excellent idea to re-inforce the frame at this point; this is difficult in view of the location, and to accomplish the purpose it would be necessary to apply a curved cross-member, so shaping the same that it would pass under, or over, the flywheel and fasten to the sidebars at a point just back of the rear arms of the motor, in the plane of the flywheel.

(H) Since it is a fair assumption that the parts throughout the whole automobile, one like the crankshaft, effected by speed, the maximum speed of the automobile on the road should be limited to something less than the original speed of the same when it was new. To accomplish this the governor would have to be set accordingly, and, in view of this possibility it would be safe enterprise to use the larger driving sprockets, making them as large as possible, consistent with hill-climbing ability on the high gear.

In the absence of a governor there are other ways of limiting power, hence, speed of the motor. If the best power, considering speed, is due to the use of a magneto (disregarding other points of design for the moment) for ignition purposes, with the same so timed as to deliver an efficient spark at the best possible angle of advance, advantage may be taken of the fact that the angle of advance should be increased with the speed of the motor for the best results. By fixing the spark so that the angle of advance will be insufficient at the higher speeds, the power of the motor will not increase with the speed, in direct proportion to speed, and at the higher speeds, the power will be below the requirement as indicated by the automobile.

In a word, independent of the inherent ability of the motor, the spark may be so set that the speed of the automobile may be limited to, say 40 miles per hour on a hard level road, and this method of treatment will accomplish the desired result, without interfering with the hill-climbing ability of the automobile, because the spark will be sufficiently advanced to do efficient work at the speed of the motor which is likely to obtain in hill-climbing work.

If it is conceded that the original speed of the automobile was 50 miles per hour on a hard level road, then, by limiting the performance to a speed of 40 miles per hour, the strains will be reduced to about 2-3 of what they were originally, and this reduction will obtain throughout the whole automobile, so that safety will be assured, and the repair will be worth while. It is just possible that it is not necessary to make such a large reducton in speed, but this is a matter which cannot be definitely determined, since it depends (a) upon the quality of the material used in the automobile; (b) the time and character of the service rendered by the same, and (c) the character of the repair work done.

This particular automobile was made in 1906; it has done hard and nearly continuous work ever since, and it has not been properly repaired at any time. The body, while it was not positively light, was by no means heavy, and the automobile was speedy; the owner took advantage of this fact as often as possible.

Considering all the attending facts, it is a reasonable assumption that the possible speed, after repair, should be limited sufficiently to reduce the extreme fiber strain in the parts to approximately 2-3 of the original figure, and this will follow in case the speed is limited to 40 instead of 50 miles per hour. In fixing this limit, the gear ratio must be so adjusted that the crankshaft rotation will be reduced in the same ratio, besides taking into account the extent of reduction of the crankpins in case they are centered and ground to make them round.

OTHER PARTS WERE PUT IN GOOD ORDER

The transmission gear, front and rear axles, and other parts of the automobile not previously mentioned, were put in good working order and demountable rims were placed on all four road wheels. A new "dual" ignition system, including a Remy magneto, was installed, so that, on the whole, the cost of doing the work, as here noted down, was not high. This cost includes new ball bearings in the jackshafts, and a considerable amount of labor in divers ways that cannot well be stated.

COST OF ACTUAL WORK DONE

Substituting a Remy magneto and a dual arrangement of the ignition system for the old multicoil and magneto, eliminating the chain drive for the magneto, and other troublesome details	$55.00
Substituting detachable rims for clincher	20.00
New dashboard	15.00
Refinishing the car (paint)	75.00
Bolts, nuts, washers, etc.	5.70
Miscellaneous cash expenditures	45.00
Salaries paid for work done in dissembling the car, repairing the side frame, overhauling the motor, and starting the final assembling process	180.00
Estimated labor costs required to complete the work	60.00
Total cost	$455.70

WITH THE AGENCIES

Eight Hudson runabouts appeared in line in the parade held in Detroit before the start of the Glidden tour last summer. G. W. Dunham, the chief engineer, is in the first car

J. S. Bretz, president of the J. S. Bretz Company, New York

Recent Wisconsin agency appointments are: Cadillac, Park Hotel Garage, E. A. Kemmerer, proprietor, Janesville, Wis.; Kissel, E-M-F, Maxwell, Stoddard-Dayton, Matheson and Flanders, Baack, Reed & Gage Co., 111-113 North Main street, Janesville, Wis.; Overland, Sykes & Davis Garage, formerly Pierson's, 17-19 South Main street, Janesville, Wis.; Ford, Blodgett & Holmes, Riverside Garage, Janesville, Wis.; Overland, Merrill Iron Works, Merrill, Wis.; Overland, Calumet Auto Co., Brillion, Wis.; E-M-F, Flanders, Collmar's Garage, Baraboo, Wis.; Overland, L. P. Helm, Baraboo, Wis.; Reo, Wilke Garage, Sheboygan, Wis.; Overland, T. H. Jacobs, Wausau, Wis.; Badger, W. T. Schwantz, Lowell, Wis.; Jackson, Fuller, Cochrane & Son, Fox Lake, Wis.; Ford, Mayville Auto Co., Mayville, Wis.

A Baltimore branch for the Washington car has been established at North avenue and Oak street. The Auto Trading and Garage Company has been organized for handling this car here. The officers of the new company are Philip Wenchel, president; Jacob Baumann, vice-president; F. W. Lilly, treasurer, and W. Howard Schweizer, general manager. Messrs. Baumann and Lilly have the State agency for the car, with headquarters at Catonsville, Md.

The recently organized U. S. Auto Company, of Cleveland, has leased a large garage on Euclid avenue for five years and has received demonstrators of the Paterson "Thirty" and the Whiting lines, for which cars the company will act as agents. E. E. Robbins is president of the company, and A. A. Grimes, recently Jones speedometer salesman, will have charge of the sales.

The John Deere Plow Company, of St. Louis, Mo., Southwestern distributor for the Jackson Automobile Company, of Jackson, Mich., has appointed the following Jackson agents in Texas: Eikel Automobile Company, San Antonio, Tex.; Wortham-Shotts Company, Fort Worth, Tex.; Lee, McKallif & Abbey, Houston, Tex.

The Korach-Kraus Motor Sales Company has been organized at Cleveland by E. J. Korach and E. F. Kraus for the purpose of distributing the De Tamble models in Ohio. The company has acquired large salesrooms on Euclid avenue.

A new home for the Pierce-Arrow car is in the course of construction at 812 North Charles street, Baltimore. This store will be occupied after May 1 by the Foss-Hughes Motor Car Company, H. J. Sturdevant, manager.

The Standard Motor Car Company has added to its agency in Nashville the Empire 20 and the demonstrating car is expected to arrive within the next few days.

The East St. Louis Automobile Company, of East St. Louis, Ill., has taken the agency for the Jackson.

The Olds Motor Works' Louisville branch has made arrangements whereby Hamilton & Dodge, of the Phœnix Motor Car Company, of Lexington, become a branch of the Olds Motor Works.

Charles E. Miller recently announced the opening of another branch at 601-603 Baronne Street, New Orleans, La., for April 1. This makes eleven stores that Mr. Miller is operating.

H. A. Reifenberg, formerly of the Detroit branch of the Warner Instrument Company, has been given charge of the new office of that company at Kansas City.

The Toledo agency for the Paterson "30" has been landed by E. F. Lienhard, one of the most enterprising dealers on the banks of the Maumee.

The Davis-Bell Hardware Company of Itta Bena, Miss., has secured the agency in that section for the Maxwell cars.

The Presto-Lite Company has established a branch in Cleveland and a recharging plant. S. M. Paxton is manager.

The Jackson will be represented in Florida this year by C. F. Irsch, at Tampa, and McIver & McKay, at Ocala.

The Deere Implement & Vehicle Company, of Montgomery, Ala., will handle the Jackson this year.

Tuschen Brothers, of Watertown, Wis., have added the White, Waverley electric and Halladay cars.

Bretz Says Torpedo is Passing

J. S. Bretz, head of the J. S. Bretz Company, returned Monday from a flying business trip to Europe. He left New York on March 9. The chief part of his time abroad was spent at Schweinfurt-on-Main, where the F. & S. steel ball factory he represents, is located; at Liège, Belgium, and in London. While in Germany he had an opportunity to see the new types of German cars.

"At the Opel factory they are getting away from the torpedo shape," said Mr. Bretz. "The newest style of body slopes slightly inward at the back, and the radiator comes almost to a point, in an effort to decrease atmospheric pressure.

"I visited Henri Peiper, of the Société Internationale de l'Electricité, at Liège, Belgium, and then returned to London. One of the most interesting things I noticed about British motoring was the almost universal use that is being made of the Rudge-Whitworth detachable wire wheels."

While in Germany, Mr. Bretz witnessed the making of some steel ball bearings, nine inches in diameter, such as are used in the heaviest types of battleships to revolve the turrets.

Owing to the peculiar bungling of a cablegram by a London hotel, Mrs. Bretz failed to meet her husband as planned, and they passed one another on the high seas.

AMONG THE GARAGES

This E-M-F car takes care of the mail service of the Detroit factory of the Everitt-Metzger-Flanders Company. During February it delivered 143,000 pieces of mail satisfactorily

Horace De Lisser, vice-president of the U. S. Motor Company

B. M. Shea, manager of the George C. John Motor Company, New York, says that each year finds a larger volume of all-the-year-around business at the garage of the company. He says that the general use of the automobile has resulted in holding hundreds of business men in New York in Summer, who formerly visited distant summer resorts. The use of the car in their cases, takes the place of tiresome and expensive Summer trips.

The garage of the Warner Motor Company, at 1204 New Hampshire avenue, Washington, D. C., is reported to have been purchased by W. H Wyman. The garage is two stories in height, with a frontage of 70 feet on New Hampshire avenue, and has about 3,000 square feet of floor space. Mr. Wyman will do a general repair and garage business, and also wishes to embark in the manufacture of machines of his own design.

The store-room and garage of the De Dion-Bouton Company at Fifty-first and Broadway, New York, is in course of reconstruction. The partitions that formly cut up the interior of the garage have been torn out and the whole space will be utilized in the near future. The shops and boiler room have been removed to a small building adjoining the garage in the rear, thus affording considerable additional room.

At Marietta, O., Hinds & Bailey will make extensive improvements to their garage and sales agency on Putnam street. An addition will be erected in the rear of the lot, giving almost double space. A new arch entrance will be made on Putnam street and a second entrance will be made on Second street.

Automobile owners in Minneapolis now have all-night service as far as regards the repairing of their automobiles. The Parger garage has started keeping open house 24 hours a day in its repair department, and this innovation permits owners to have their cars washed or repaired at all times.

The Carl H. Page Company, 1627 Broadway, which handles the Chalmers cars, is seeking more room for its garage. Garage Manager James Bell says he sent out 116 new cars during March, but was seriously handicapped by lack of space. No new location for the garage has been selected.

At New Philadelphia, O., Edward Goodwin is remodeling the skating rink into a modern garage, which will be opened at once. The main portion of the building will be used for storage purposes and the rear is fitted as a repair shop.

Eastern Texas will have its first garage when the East Texas Automobile Company opens its quarters in Palestine, Tex. It will be located in the Wainwright Building, on Avenue A, and will be managed by W. H. Brooks.

Work has been begun on the new Packard garage in Portland, Ore. The building, which is located at Twenty-third street and Cornell road, will cost $30,000.

The Woodville Garage Company, of Woodville, Sandusky County, O., was incorporated with a capital of $10,000 by Fred H. Hartman, W. H. Price, Charles A. Kuhlman, William Uschel and J. T. Smith.

A. J. Schnell, the Scranton, Pa., agent for the Pullman, will erect a one-story brick garage, 40 by 74 1-2 feet, at 119 Jefferson avenue. It is expected that it will be ready for occupancy some time next month.

Work on the new Stevens garage to be installed in the Mosgrove block, Urbana, O., is progressing rapidly and will be ready for occupancy May 1.

Brief Personal Trade Mention

Irving H. Manning, recently with the American Locomotive Company, has joined the selling force of the Warner Instrument Company, as special representative. Mr. Manning has been selling cars for twelve years or more. For five years past his headquarters have been New York City.

Walter Schmunk, formerly of Cleveland and for several years identified with the automobile industry, has left the Boston branch of the White Company to return to Cleveland where he will be connected with the sales department of the Peerless Motor Car Company.

Julian G. Kursten, paying teller of the Union Trust Company of Detroit, and assistant manager of the Clearing-house Association, has resigned to accept a position with the selling force of the Anderson Carriage Company, making the Detroit Electric.

John W. Bate, designer of the Mitchell car and superintendent of the works of the Mitchell-Lewis company, of Racine, is enjoying his first extensive vacation trip. Mr. Bate will visit various countries in Europe, especially Italy.

E. J. Bohannon, assistant secretary of the Louisville Automobile Club, has resigned to become identified with a business house. The resignation will become effective May 1. His successor has not yet been appointed.

A. B. Barkman, for over four years connected with the Maxwell-Briscoe interests, and who has been one of the district managers of the company, has been appointed sales manager of the Maxwell organization.

George H. Votteler, for many years prominent in Cleveland business circles has entered the automobile field and accepted an offer from the Sterling Motor Sales Company, Ohio agents for the Sterling.

F. A. Bowers, for the past 10 years master mechanic and designer of pressed-steel stamping tools for the O. A. Smith Company, has resigned. His plans for the future are indefinite.

Office building recently added to the Maxwell-Briscoe Motor Company's plant at Tarrytown, N. Y. The architecture is in keeping with the suburban landscape

Merle L. Downs, secretary of the A. L. A. M. Show Committee

The Continental Motor Manufacturing Company, of Muskegon, Mich., manufacturer of automobile and marine motors, is constructing an addition to its machine shop, 132 feet by 160 feet, and adding two additional floors to its stock warehouse, which will give additional floor space of about 12,000 square feet. An extension, 40 feet by 150 feet, is also being made to the motor-testing building. The additions will give an additional floor space of approximately 40,000 square feet. The construction work is being pushed and it is expected will be ready for occupancy about May 1.

The Mitchell-Lewis Motor Company, of Racine, Wis., manufacturer of the Mitchell, is completing its new testing track, which is one-half mile long and wide enough for two or three machines abreast. A track was built last year, but did not prove adequate because it was built hurriedly. The new track is built to be permanent. The completion of this track obviates the necessity for using any public highways for testing purposes.

The West Milwaukee shops of the Chicago, Milwaukee & St. Paul Railway are turning out from three to five "automobile" freight cars daily, the demand having grown enormously. Manufacturers whose plants are situated along the Milwaukee road lines are not satisfied with the old-fashioned freight car. The new cars are of 60,000 pounds capacity and are marked "Automobile" on either side.

The Kelly-Toledo Tire & Rubber Company has been organized at Toledo with a capitalization of $375,000. Charles F. U. Kelly, for many years identified with the Akron industry as sales manager, will be general manager. The new company will erect a large factory in Toledo, employing 500 men, and will devote most of its time to the manufacture of automobile tires.

Papers have been filed with Secretary of State Thompson of Ohio increasing the capital stock of the Firestone Tire & Rubber Company from $5,000 to $4.000,000. The company, which was formerly a West Virginia corporation, was recently chartered with the small capital to permit of its organization before the capital was increased to the amount desired.

N. Lazarnick, photographer, with headquarters in New York and a branch office at 870 Woodward avenue, Detroit, is making a tour of the principal automobile manufacturing centers with a view to opening branch establishments at Cleveland, Indianapolis, and such other points as would seem to be of sufficient promise to make it worth while.

The National Rubber Tire Manufacturing Company has been organized and incorporated to manufacture automobile tires, non-skid treads, and inner tubes. The company expects to complete arrangements for manufacturing within the next thirty days. The present headquarters is Bullitt Building, Philadelphia, with Clifford R. Skinner in charge.

The Cass Motor Truck Company, capitalized at $300,000, has been organized at Detroit, for the purpose of building commercial vehicles. The incorporators are: John I. Turnbull, George G. Epstean, Alex M. Spater and F. W. Ferguson. The company is negotiating for a site upon which an extensive fireproof factory will be erected.

The Packers' Motor Truck Company has been organized in Pittsburg with a capital of $100,000 by W. M. Zoller and E. K. Callahan, of this city; James F. McGarry, of East Liverpool, Ohio; Geo. P. Pratt, of Buffalo, N. Y., and Albert M. Schenk of Wheeling, W. Va. The company will manufacture two and three-ton trucks.

At a meeting of the stockholders of the Findlay Carriage Company, of Findlay, O., it was decided to increase the capital stock from $50,000 to $150,000 for the purpose of opening a department for the manufacture of automobiles. The first car, a gasoline runabout, has been finished and tested.

C. West & Company, carriage builders, who have been located in Duquesne Way, Pittsburg, since 1847, are opening an automobile department, which will be under the management of W. F. Melhuish, Jr. They will handle the Simplex car, and will also build bodies for the Buffalo truck chassis.

The Lozier Motor Company has purchased 65 acres of land in the east end of Detroit, at an approximate cost of $2,000 an acre, as the site for an immense plant. It is announced that construction work will begin early in April. The location has both railroad and street car facilities.

At the annual meeting of the board of directors of the Keller Manufacturing Company, Philadelphia, the following officers were elected: Julius Keller, president; W. P. Pressinger, Wm. H. Keller, S. W. Prince, vice-presidents; Francis J. Rue, treasurer; C. S. Bell, secretary.

It was rumored last week that the price of the Hupmobile, as made by the Hupp Motor Car Company, Detroit, would be advanced in price to $800 from $750. Later advices direct from the company are to the effect that the price will not be advanced.

The Pierce Motor Company, of Racine, Wis., has already started its engineers and draftsmen on 1911 models. The torpedo style, which is being produced in limited quantities, will be incorporated in the regular 1911 line.

The Franklin Commercial Truck Company has been formed at Franklin, Pa., by Charles H. Sheanley, Charles E. Trace and Harry A. Myers, and will manufacture an automobile truck.

The Consumers Rubber Company, of Cleveland, has taken the agency for Star tires. The Star Rubber Company, Akron, began to make automobile tires a few months ago.

The Hercules Specialty Company, of Grove City, Pa., has secured James McIntosh as superintendent, and will begin the manufacture of motor trucks at once.

The third semi-annual dividend of 3 1-2 per cent. was paid April 1 on the preferred shares of the General Motors Company.

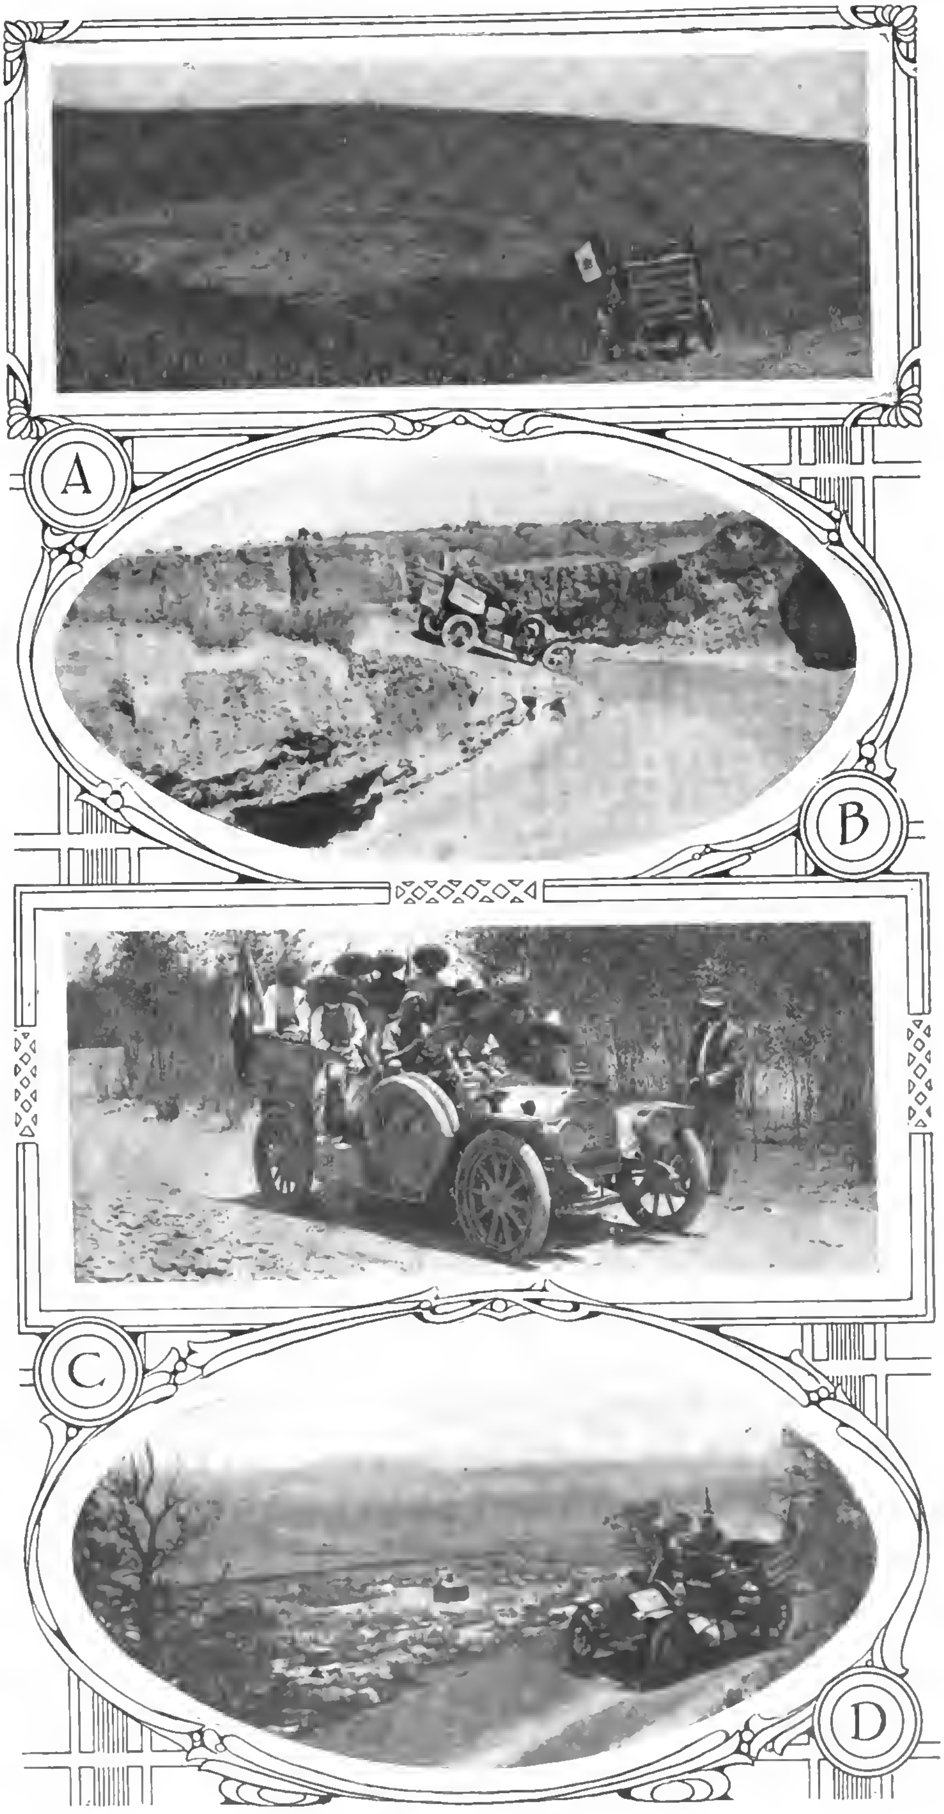
FLAG TO FLAG

With a score or more cars assured of entry in the Flag to Flag Contest for the Wahlgreen trophy, which starts at Denver City May 2 and finishes at Mexico City, the event promises an interesting and valuable trip. The course, as laid out, is about 2,500 miles long and is largely planned through country that is new to the automobile.

The course will be south from Denver, through Colorado Springs, Pueblo and Trinidad to the southern boundary of Colorado. This country is a desert during the greater part of each year, save for the spots where irrigation has served to make it a luxuriant garden. In sight of the route, to the westward, the snowy caps of the Sierra Blancas tower into the Italian blue of the unclouded sky, while the exhilarating air and good roads lend themselves to the enjoyment of the tourist. Crossing the New Mexican boundary, the course leads on through the Raton foot hills and stretching southwestward enters Texas in the rolling Panhandle country. The route touches Amarillo, San Angelo, Kerville, near the center of the State, and then, swinging back, circles through San Antonio. From thence the course is straight to the Rio Grande, crossing at Eagle Pass in our romantic sister republic. The route from the border traverses the State of Coahuila to Torreon, thence south to Zacatecas and Aguas Calientes. From this point, rich in interest for Americans, the route swings easterly through Celaya, San Juan del Rio and Tula to the capital.

It has been estimated that the trip should cost about $5 a day for each man and an allowance of $5 a day for each car should also be made. Gasoline and oil will be furnished free to entrants by the Waters-Pierce Oil Company at numerous supply stations all the way from Denver to Mexico.

The tour is under the management of G. A. Wahlgreen, donor of the trophy, who is assisted by G. A. Blanchard, assistant manager. The aim of the project is largely educational, as the country traversed en route is rich and able to buy large numbers of cars.



A—Road Leading Down Into Raton Valley, a 3,000-Foot Drop
B—Chalmers Pathfinder in an Arroyo, 35 Miles from Trinidad
C—Knipper Giving a Crowd of Mexicans Their First Auto Ride
D—Descending Raton Mountain, with the Town of Raton Below

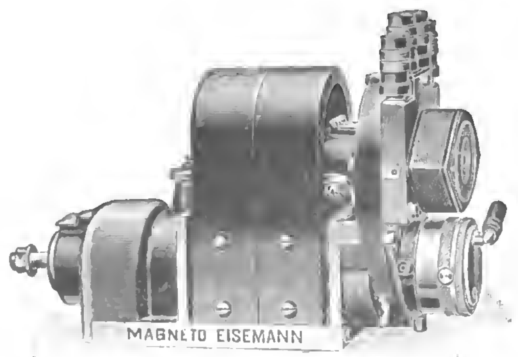
PROMINENT ACCESSORIES

AUTOMATIC ignition timing has frequently been tried on automobile engines, but hitherto has met but a slight measure of success. Although on a number of cars the absence of the usual timing lever may be remarked, the majority of these avoid it by the use of fixed timing. However, no one has ever attempted to dispute the desirability of an automatically timed ignition, if its apparently inherent disadvantages could be done away with; and the announcement of the makers of the Eisemann magneto that they have perfected such a device will be received with the greatest interest by all automobilists.

The device in question is simply a fly-ball governor arranged on the magneto shaft, and built in with the magneto as a unit. The governor balls act through bell cranks to shift a sleeve on an extension of the armature spindle. This sleeve is provided with internal threads of a square section which engage with corresponding external threads on the armature spindle. These threads are of a steep pitch, and as the governor acts they serve to rotate the armature shaft relatively to the governor shaft, through which the driving power is transmitted.

It will be noted that in this system the armature as a whole is rotated, thereby causing the break at the time of the maximum strength of current regardless of the amount of advance. Such a system, of course, gives a spark of equal intensity at a given speed of the magneto, and permits of utilizing the hottest sparks of which the magneto is capable. It is stated that because of this a quarter turn of the crank suffices to start the motor.

Another ingenious feature has been incorporated in this magneto, namely, a device for facilitating setting the armature with respect to the crankshaft. In the rear portion of the regulator housing is a slot into which may be inserted a correspondingly shaped key. The sleeve, which is rigidly connected to the armature shaft, is square and the key will fit into either of two sides of the square. When the key is inserted, the armature is held stationary in the position in which the platinum points of the circuit breaker begin to move away from each other. With this device it is no longer necessary to look at the make-and-break mechanism to determine the moment at which the points are separated. The Eisemann magneto is now handled in this country by the Eisemann Magneto Company, 225 West Fifty-seventh street, New York City. The magneto itself, of French manufacture, is favorably known and is used as standard on a number of high-grade cars. The company is also prepared to meet the requirements of the aeroplane industry, having brought out a lightweight magneto specially designed for use on aeronautic motors, in which aluminum has been freely used.



Eisemann Magneto with Automatic Timing

The Safety Tire Gauge Company, 315 Dearborn street, Chicago, is offering to automobilists the type of tire gauge illustrated herewith. It is a combined pump connection and pressure gauge. It makes a very convenient pump connection, and by means of the protruding rod, which is forced out by the air pressure within the body of the device, the pressure is always indicated. The gauge is stoutly constructed, and will stand hard knocks in the tool box without injury.

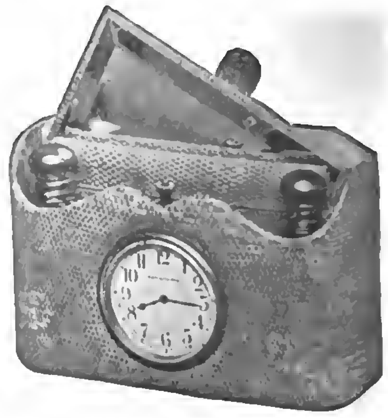
"Safety" Tire Pressure Gauge

If automobile engines ran at a constant speed, the problem of electric lighting and storage would be simple, but as the engine speed varies from zero to 1,500 revolutions a minute, some method of governing the output of the generator is necessary. The latest method of accomplishing this end is by the Ward Leonard system of electric lighting, which has been brought out by the Ward Leonard Electric Company, Bronxville, N. Y., and was specially designed for automobile service.

In this system the generator is a small dynamo mounted on the engine, by which it is driven through a magnetic clutch. When the dynamo speed is such that the dynamo voltage is equal to or slightly greater than the battery voltage, the circuit is established automatically, and the output of the dynamo charges the batteries. When the dynamo slows down, the circuit is automatically broken. The automatic switch also breaks the circuit to the magnetic clutch when the charging amperage exceeds the proper amount. Two storage batteries are provided, one of which is used for lighting, while the other is used for ignition. Besides the usual lamp equipment, the electric system will also provide current for a horn, a reading light, a speedometer light, a cigar lighter and a trouble light.

The Mechanical Instrument Company, 120 Liberty street, New York City, has brought out an instrument under the name of the "Mico reciprocating meter" for registering accurately the total feet of travel of all reciprocating motions. The instrument resembles a large speedometer in appearance, having a circular dial face reading up to 10 feet, on which a hand travels clockwise, and a counter reading up to 100,000,000 feet. It is connected with a crosshead or other reciprocating part by a flexible bronze cable which winds around a drum on the rear of the instrument. This handy little meter will be of the greatest possible value to factory engineers and superintendents, in that it will enable them to check up the operation of steam pumps, and other similar machines with accuracy, while its simplicity makes it easy operable by any employee.

Limousine owners will doubtless fancy the toilet rack watch which screws into the toilet rack or vanity box usually included in the equipment of closed cars. The watch is in three parts, two of which screw together, clamping between them the leather of the case. The back snaps on, making the mechanism dust and damp-proof. The watch may be wound and set without removing from the rack. The watch regularly furnished has seven jewels, Breguet hairspring, cut expansion balance and other standard features. It is made by the New England Watch Company, Waterbury, Conn., and should be warmly greeted by the trade.



"Limousine" Watch for Closed Cars

THE AUTOMOBILE

LOS ANGELES MOTORDROME OPENING

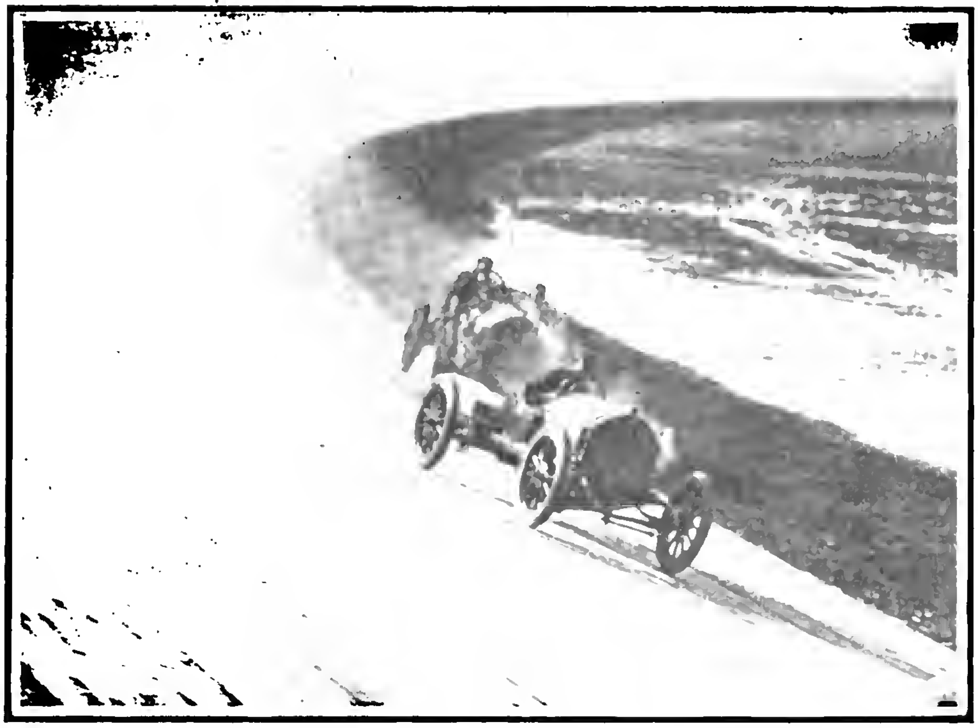
LOS ANGELES, Apr. 13—Racing began at the Motordrome on last Friday under favorable auspices with a scheduled meet of seven days, and from indications, thus far, it is anticipated that the closing on Saturday will be in a blaze of enthusiasm. The Motordrome is more interesting than it otherwise would be, because it is along absolutely new lines, and represents something definite; with the expectation that it will prove out the real capability of the circular track. Heretofore, circular track work was hampered by unavoidable but interfering considerations. Tracks laid out specifically for horse racing offered so many disadvantages that failure to make speed made it impossible for experts to decide as to whether or not the shortage was due to centrifugal force, and other true phenomena, which belong properly to the circular track, or to lack of suitable characteristics of the roadbed.

In this case the track is one mile in circumference. The width of the track available for the cars is 45 feet, and the outer edge of the same is 15 feet higher than the inner edge. The amount of the embankment, therefore, is represented by an elevation of 15 feet in 45 feet. A safety zone is provided around the inside of the track proper, which zone is 30 feet wide, made of dirt. The track proper is built up of 2 by 4 deal timber on edges, supported by a suitable framing which rests on vertical members, with a distance between bents which is regarded as consistent with the load to be supported, considering the ability of the 2 by 4 deal roadbed.

Anticipating a high rate of speed on the part of the racing automobiles, and remembering that casualties are possibilities which increase in the ratio of the speed squared, the design of the track is such that even if the embankment proves to be inadequate for the purpose, a further safety measure is induced through vertical backboard which runs all around the outer edge of the track, provided with T-rails, the first of which is 24 inches above the level of the platform, and the second is 7 inches (centers) above the first. It is anticipated that a car, in the event control is lost, will render a "swipe" below against the T-rails, and skid along for a sufficient distance to dissipate the energy represented in the moving mass, doing the least possible damage in the process.

A SPEED BRUSH BETWEEN BUICK, COLE "30," AND APPERSON AUTOMOBILES ON LOS ANGELES BOARD TRACK

Should a car take fire, which is within the range of possibility, a means is provided for prompt quenching of the fire, and this is deemed of importance, in view of the fact that the track is of wood, and remembering that water is not efficacious as a fire-fighting instrument in the presence of gasoline. For the purpose of quenching any incipient flame, a strip 5 feet wide runs all around inside of the dirt auxiliary track, which strip is composed



A LONG CHASE BETWEEN DE PALMA IN FIAT AND LESCAULT IN PALMER-SINGER

taking advantage of wide experience.

Six repair pits are located in front of the boxes and extend around the circle for a distance of 300 feet; they are situated in a radial direction 40 feet in from the board track, and the space is covered by the same 2 by 4 scantling material as that of which the track proper is made. The repair pits are built in the light of experience under racing conditions, every facility is afforded for prompt and accurate work, and the location is such that the officials, the spectators and the press will be enabled to witness the rapid fire process which is so essential to success under racing conditions, and also to judge of the necessity and the character of the repair work undertaken. The press stand, which is well appointed and sufficiently commodious for the purpose, is located directly opposite repair pits.

of sand in sufficient presence to serve for every requirement, and it is claimed by the track designer that it may possibly serve as a good landing place for a car if it runs wild, provided it travels in the direction of the axis of the circle.

AMPLE ACCOMMODATION FOR THE PATRONS OF THE TRACK

The grand stand stretches for 2,000 feet around the periphery of the track, and a box section for 1,000 feet. The box section is roofed over, and has accommodation for 3,000 people. In the grand stand the seats are six rows deep, and the seating capacity is stated to be 11,000 persons. Safety measures obtain at every point; access to the infield is by subways from without, and an aero club building is placed to one side of the field inside of the track. It includes every facility for the intended purpose. The infield is sufficiently large to afford ample maneuvering space for aeroplanes, and the spectators, from their point of vantage in the boxes or grand stand, could not be better placed.

A CONSIDERABLE UNDERTAKING

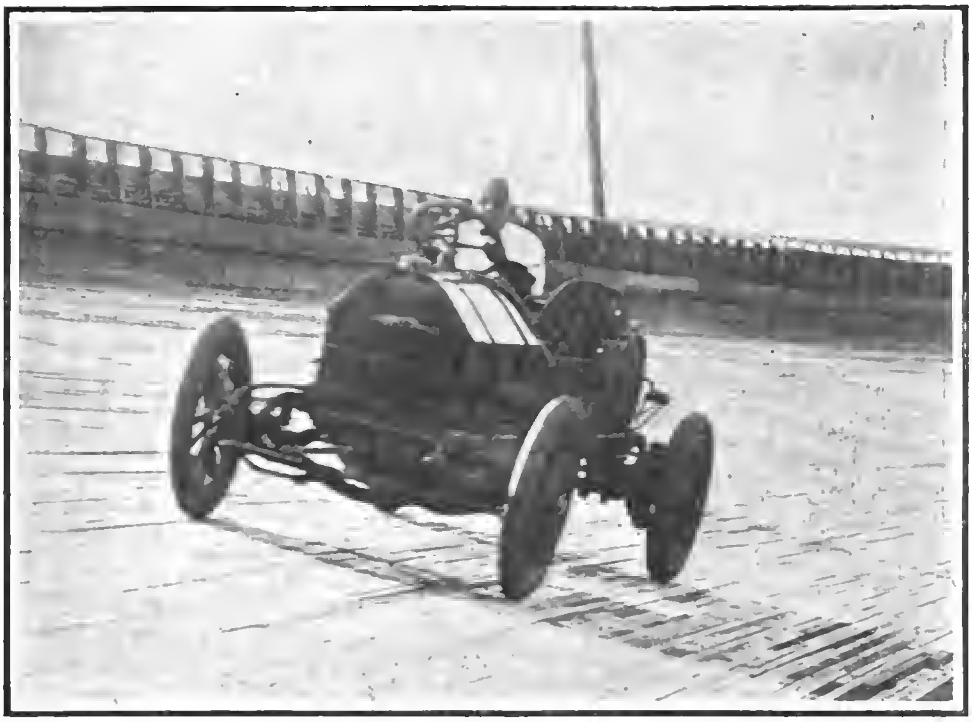
Visitors at the Motordrome will scarcely be in a position to judge of the enormity of the undertaking; they will hardly appreciate the fact that the building of the track called for the use of 3,000,000 feet of Oregon pine, nor is it possible to fully realize what it means to procure this material and whip it into shape within the short time which elapsed from the ordering of the material in December last to the official opening of the track on April 8. The actual work of building the track was started on February 1, and it went forward unceasingly to the finish, due to the foresight of the management, and the completeness of the plans which were made under the direction of Manager Moskovics, thus bringing into play the facility which comes from close application,

LOCATION WELL SELECTED

The distance from the ocean is barely three-fourths of a mile, and to Venice is 1 1-2 miles. Venice is a town with a population of 10,000, and it is 11 miles distant from Los Angeles. The transportation facilities are by means of two trolley lines, one of which is designated the Venice short line, and the other is the Playa del Rey road. A loop enters the outfield of the Motordrome, adjacent to the grand stand and the boxes, so that visitors who may not care to ride in automobiles will find the trolley efficacious, and the scenery as pleasant as the air is balmy. There are a large number of automobile owners in and about Los Angeles; it is the automobile center of the Pacific Coast, barring the rivalry of "Frisco" and vicinity.

The events scheduled for the present meet are, in the main, composed of stock chassis entrants, and the scheduled dis-

HARROUN, MARMON, DOING MILE IN 49 SECONDS PRELIMINARY TO SOME REAL WORK tances are 5, 10, and 25 miles. Added interest is due to the longer distance races, one of which is for 100 miles, and a second is in the 160-230 class, another for the 230-300 class; then comes the 301-450 class, and finally the 451-600 class. The last named is the more formidable, unless it proves that the 24-hour event is, for which the prize is $1,000 in cash for the winner, $500 in coin for the second, $300 for the third, $200 for the fourth, and the right to participate for the rest. It is predicted that the two-hour race for stock chassis in the class having over 600 cubic inches displacement will be of more than passing interest in relation to which a remark or two may not be out of place.



HANSHUE IN APPERSON JACKRABBIT COAXING THE FIELD TO COME ON

SUMMARIES OF RESULTS

Friday, April 8—One-mile trial, Benz (Oldfield), 36.22, new American track record.

One-mile trial, amateur, Fiat (Bragg), 37.56.

Ten-mile trial, Simplex (Robertson), 6.31.37, new American track record.

Two-mile trial, Darracq (Kerscher), 1.18.29, new American track record.

Five-mile trial, Fiat (De Palma), 3.15.62, new American track record.

Ten-mile, Class C, 451-600 cubic inches piston displacement, Knox (Oldfield) won, Apperson (Hanshue) second, Isotta (Marquis) third. Time, 7.49 2-5.

Ten-mile chassis, 161-300 cubic inches piston displacement, Cole (Endicott) won, Buick (Nikrent) second, Firestone (Linthwaite) third. Time, 9.03.25.

Five-mile, free-for-all, Class D, Fiat (De Palma) won, Simplex (Robertson) second, Darracq (Kerscher) third. Time, 3.16.3.

Ten-mile, 230-300 cubic inches piston displacement, Marmon (Harroun) won, Dorris (Siefert) second, Corbin (Livingston) third. Time, 1.25.22.

Saturday, April 9—Five-mile, Class C, 451-600 displacement, Knox (Oldfield) won, Apperson (Hanshue) second, Isotta (Marquis) third. Time, 3.52.20.

Ten-mile, free-for-all, Simplex (Robertson) won, Fiat (Bragg) second. Time, 6.35.6.

Fifty-mile, stock chassis, 161-230 displacement, Cole (Endicott) won, Buick (Nikrent) second, Warren-Detroit (Miller) third. Time, 43.49.69 (National Speedway record).

Ten-mile, stock chassis, handicap, Ford (Hampton) 3.10, won, Stoddard-Dayton (Livingston) 25, second, Knox (Oldfield) scratch, third. Time, 10.10.1.

COLE "30," ENDICOTT DRIVING, IN A RECORD PERFORMANCE ENDING EASY

Sunday, April 10—Fifteen-mile, stock chassis Class C, 160 displacement. Fiat (De Palma) won, Isotta (Marquis) second, Hupmobile (Kelly) third. Time, 17.07.81.

Five-mile, Chanslor and Lyon handicap, Palmer-Singer (Lescault) one minute, won, Stoddard-Dayton (Livingston) 35 seconds, second. Isotta (Marquis) one minute, third. Time, 3.23.16.

Five-mile, 231-300 class, Marmon (Harroun) won, Dorris (Siefert) second. Time, 3.55.97.

Fifty-mile, Venice sweepstakes, 451-600 class, Isotta (Marquis) won, Stoddard-Dayton (Livingston), second. Time, 39.20.69 (National Speedway record).

Five-mile handicap, Simplex (Robertson) scratch, won, Palmer-Singer (Lescault), 50 seconds, second, Stoddard-Dayton (Livingston), 30 seconds, third. Time, 3.29.28.

Five-mile, free-for-all, Fiat (Bragg) won, Simplex (Robertson) second, Darracq (Kerscher) third. Time. 3.15.89 (American record).

FELLOWSHIP was the keynote pervading the harmony that surrounded the first annual banquet of the Association of Licensed Automobile Manufacturers at the Hotel Astor on the evening of April 7. The attendance included about 150 and was composed of representatives of practically all the companies engaged in the making of the motor car under the Selden patents as well as the press.

The function was held in the main dining-room of the hotel and the menu was of particular choiceness and completeness. The fundamental motive in all the addresses was the advancement of the automobile and the subject was treated from a great variety of angles.

The Hon. Fred M. Warner, Governor of Michigan, the leading State in the making of motor cars, was the guest of honor. His address was devoted in large measure to tracing the influence of the automobile as an actual factor in modern development, with particular reference to its importance to the State of Michigan as an automobile center.

Governor Warner prophesied that the Federal Government would cooperate with the individual States at no distant period in advancing the cause of good roads in a practical way to obtain results.

Job Hedges acted as toastmaster and was at his wittiest in his introduction of the various speakers and in making pat comments upon their efforts to entertain and explain.

Arthur Brisbane, editor, made a number of striking statements with regard to the development of the automobile. One of these was as follows: "The automobile does not destroy city pavements. The vast bulk of the damage in this respect is accomplished by the caulks with which the shoes of horses are armed. In the day when the horse shall be no more, I venture to prophesy that the saving in one big city in the matter of paving and repairs in one year will reach a

Scene in the Banquet Hall of Hotel Astor Upon the Occasion of the First Annual A. L. A. M. Banquet

figure that will be of sufficient size to cover the purchase of all the automobiles made in the country during that year."

Other speakers were Joseph E. G. Ryan, of Chicago, and William H. Edwards, Commissioner of Street Cleaning of New York.

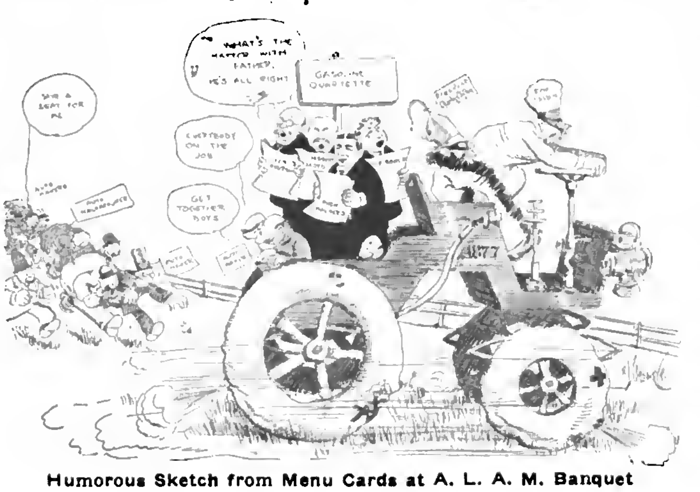
The feature of the affair was the incident attending the presentation of a loving cup to Colonel Clifton and a Steinway Baby Grand piano to Mrs. Clifton, on behalf of the association.

At the appropriate period of the speaking, Colonel Pope arose and said that he had a duty to perform that was a real pleasure. He pointed out that such labor as had been given freely by Colonel Clifton in the interests of the association could not be bought with money.

In accepting the cup, the president said that the basis of presentation would have to be altered before he would be easy in his mind about receiving it. He said that whatever success he had achieved as head of the organization was due to the fact that he had been accorded efficient support by the other officers and members of the association and that credit was due to them, even more than to himself. He made an earnest plea for continued co-operation and said that the only basis upon which he felt justified in accepting the cup was that it should be regarded as a rallying point for the forces of the association.

As he was about to resume his seat amid a volley of applause, Mr. Hedges turned toward Colonel Clifton and, when quiet had been restored, said that every member of the association knew how much valuable time had been given by Colonel Clifton to the association's work. That was in the past and could not be recalled.

But during all that time in which Colonel Clifton labored to build up the motor industry he almost forgot that he had a home. He could not forget his helpmeet and the partner of his joys and sorrows, but if had not been for the free service he gave the association, he undoubtedly would have spent more time in her company. Therefore, while the success of the association was sufficient reward in itself for Colonel Clifton, the association thought this a good time to make some sort of amends to Mrs. Clifton for the loss of her husband's company.



Humorous Sketch from Menu Cards at A. L. A. M. Banquet

R. H. Johnston, of the White Company, composed some amusing parodies that met with much applause.

The full list of those who attended the banquet is as follows: C. B. Ames, John E. Baker, F. A. Barker, J. B. Bartholomew, A. G. Batchelder, Leigh Best, Samuel R. Betts, W. R. Blodgett, Preston H. Breed, Arthur Brisbane, Benjamin Briscoe, Frank Briscoe, Geo. H. Brown, M. J. Budlong, H. P. Burchell, Geo. H. Buzby, Henry Caldwell, Hugh Chalmers, Julian Chase, Coker F. Clarkson, Charles Clifton, H. E. Coffin, Lee Counselman, James G. Cowling, H. F. Cuntz, Duncan Curry, S. T. Davis, Jr., Horace De Lisser, H. F. Donaldson, F. D. Dorman, M. L. Downs, Geo. J. Dunham, Calvin H. Dunlap, W. C. Durant, J. Frank Duryea, Arthur N. Dutton, Hayden Eames, William H. Edwards, C. A. Emise, Hermann G. Farr, T. J. Fay, Frederick P. Fish, Edwin A. Fitts, Harry Fosdick, Geo. G. Foster, Lewis H. Freedman, W. N. Freeman, C. W. Fuller, R. D. Garden, C. J. Giegerich, J. W. Gilson, Charles Glover, Morris A. Hall, C. C. Hanch, L. P. Hardy, W. H. Harrison, M. S. Hart, Elwood Haynes, E. W. Headington, Job E. Hedges, Thomas Henderson, Edward R. Hewitt, C. C. Hildebrand, William H. Horner, Russell Huff, H. L. Humphries, Wm. R. Innis, R. B. Jackson, R. H. Johnston, H. B. Joy, James Joyce, F. M. Kirby, L. H. Kittredge, N. Lazarnick, Frank C. Lewin, Herbert Lloyd, V. A. Longaker, Henry A. Lozier, David S. Ludlum, G. G. Luthy, C. J. McIntosh, Alvan Macauley, J. M. Mack, Steven S. Manes, C. W. Matheson, F. F. Matheson, Walter C. Marmon, W. H. Marshall, J. S. Marvin, J. D. Maxwell, A. N. Mayo, W. S. M. Mead, William E. Metzger, F. L. Mitchell, Guy E. Mitchell, C. J. Moore, S. H. Mora, W. J. Morgan, W. G. Morse, A. C. Newby, M. H. Newton, H. W. Nuckols, Thomas C. O'Connor, R. E. Olds, R. M. Owen, Carl H. Page, I. H. Page, A. P. Palmer, E. F. Peer, John F. Plummer, Albert L. Pope, Harold L. Pope, George Pope, C. F. Pratt, Howard E. Raymond, William A. Redding, Alfred Reeves, Samuel Regar, A. L. Riker, A. W. Robinson, Frank W. Roche, E. H. Rounds, E. F. Russell, R. H. Salmons, P. D. Schenck, Kenneth B. Schley, E. E. Schwartzkopf, George B. Selden, Albert E. Smith, H. O. Smith, F. B. Stearns, Oscar Stevenson, W. S. Stevenson, Walter Stewart, C. G. Stoddard, Geo. H. Strout, Walter Sullivan, William M. Sweet, H. M. Swetland, E. L. Thomas, E. R. Thomas, Thomas H. Thomas, Carll Tucker, W. H. Van Dervoort, R. B. Van Dyke, S. D. Waldon, C. E. Walker, W. C. Walker, Walter Wardrop, Hon. Fred M. Warner, J. W. Wellington, O. H. L. Wernicke, J. C. Wetmore, William T. White, Walter C. White, Windsor T. White, Alexander Winton.

Little daughter of Mr. and Mrs. W. C. Johnson, assistant general manager of The Waverley Company. Mrs. W. C. Johnson and Mrs. W. F. Taylor graced the seat of the Waverley Electric, enjoying the privilege of chaperons to the " Belle," who appeared to appreciate the situation.

RECENT PIERCE-ARROW FACTORY ADDITIONS

Even Winter Weather Couldn't Stop Progress

Panorama view of the Pierce-Arrow plant along Great Arrow avenue. The three-story structure in the foreground is one wing of the original body building, while at the right may be seen one of the four-story 350 by 60 foot wings just added to it. At the left is shown one end of the Administration building.

ENLARGEMENTS of the largest automobile factory in Buffalo, some of them practically accomplished, others under way or planned for the immediate future, and in conjunction herewith a final, long-expected announcement to the effect that the same factory will presently manufacture a heavy-load, high-powered automobile truck, constitute steps in the onward march of the automobile industry which must attract national and international attention by reason of their intrinsic interest.

The factory in question is that of the Pierce-Arrow Motor Car Company, and the public interest attaching to the enlargements of its activities, as referred to, lies rather in the promise of a greater output of a favorite car of high grade than in the encouragement which the company's success must afford for all automobile manufacturers who may wish to adopt its methods, highly deliberate as they have been, yet leading safely and quickly to large production and an eminent position in the industrial world.

The truck which the Pierce-Arrow company will manufacture in one of the new buildings to be erected for this purpose has been on trial for about two years. It was loaned to a tire manufacturing company for five months with a view to giving it the hardest possible usage; namely, such as the tire company found necessary in order to test its own output of truck tires to destination, and, even during its earliest experimental days, the new model truck bore itself as a true prime mover of heavy loads over roads of all descriptions, never requiring outside assistance or roadside repairs. After having observed the progress of truck construction all over the world for a number of years, without feeling quite sure that full value for commercial work was produced anywhere, or that the manufacture of trucks could be undertaken properly in a plant intended for the production of pleasure vehicles, the designers of the experimental Pierce-Arrow truck had the satisfaction, when the time finally seemed ripe for active steps, to find that their observations had rounded themselves into a full-fledged conception of the type of truck most needed and most economically useful, but also most difficult to produce for the variable American road conditions; the truck of a load and power rating far exceeding that of most commercial vehicles in successful use.

The contemplated production of this heavy truck is only in small part responsible for the new enlargements of the Pierce-Arrow plant. The floor space, the mechanical equipment and the number of employees are being increased in all departments, and the fact that this expansion can take place without interfering in the least with the prosecution of the daily routine of work brings in an element of absorbing interest far beyond the automobile industry. The factory, as it was planned four years ago and as it became ready for occupancy in 1907, was laid out with just this

Giving an idea of the size of the new storehouse and assembly building. To carry materials used in the new buildings it was necessary to run two lines of railroad track into the Pierce-Arrow yards. One, with a line of cars on it is shown, the other being in the extreme rear of the site or foreground of the photograph.

The new Pierce-Arrow plant from the rear. On the left are the two almost completed wings of the new body building. The small building, just inside of the fence, is that for motor testing which is to be enlarged. The structure on which work is shown to be in progress is the nickel-plating building, while to the right is the new storehouse and unit assembly building.

possibility of expansion in view and yet without any sacrifice of economic advantage. But it was thought at the time that the facilities provided would be sufficient for a number of years.

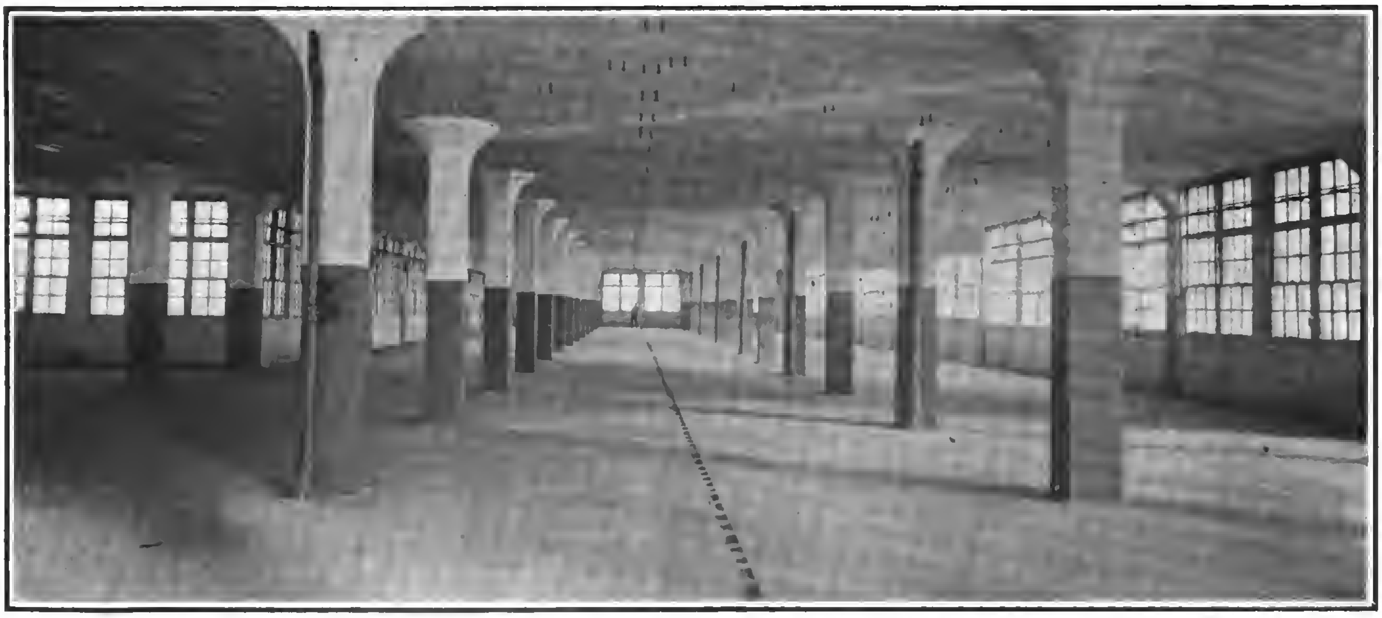
A brief retrospect will give the best idea of the foresight employed and of the value which will flow from it when factory managers from other cities and countries take note of the manner in which the plant has been made susceptible of expansion without any piecemeal addition of incongruous features or buildings.

The Pierce-Arrow plant of 1907 was one of the first great factories in the world built exclusively for the production of the highest grade of automobiles on a large scale and fitted no less for the welfare of employees than for solution of all problems in manufacture and independent research along lines of improvement. The ground plans bore evidence of the importance attached to economical handling of stock and parts. From the freight and express cars, through the inspection department all materials passed with strict reference to the order of the successive processes which they must undergo, before finally reaching the department of assembling. Here improved methods for saving labor and space were well instanced in two traveling cranes, which carried not only whole chassis, but also motors and other units, so that wide aisles for wheeled trucks could be entirely dispensed with. Saw-tooth roofs were used wherever possible and in the higher buildings the combination of steel and glass secured an abundance of daylight, rendering artificial lighting almost superfluous on even the darkest days. This was part and parcel of those provisions for the comfort of employees in which enlightened self-interest meets the demands of humanity, with the understanding that only ideal working conditions will produce the best workmanship. Other features of this nature were the hygienic kitchen, bakery, meat dressing plant, ice plant and laundry and the great dining hall seating 800 persons, as well as the most improved system of individual lockers, bicycle racks and wash bowls with towels and soap.

When this factory was taken into use, Buffalo immediately took great civic pride in it. It became one of the industrial show places which all visitors to the city must see. Men from England, France, Germany and Italy came to see for themselves how structural and production problems had been met. The machinery installed in this plant was all new and designed to give the highest efficiency in the handling of the work and with special reference to the machining of the grades of steel required for select automobile construction. Additions to this equipment have been made since, as machine tools have improved.

For little more than two years this plant has been generally considered a model of modernity and thoroughness, and the enlargements now in progress are bringing out its adaptability.

(Continued on page 735)



Ground floor of the new storehouse and unit assembly building. This floor is now being used for the reception of raw material. The second floor of this building, exactly similar in aspect, is used for finished stock and the third and fourth for the assembly of units such as motors, transmissions, rear axles, carbureters, steering gears, pumps and clutches.

Advanced Methods Obtain in the National Plant

By THOS. J. FAY

QUALITY is induced into an automobile in proportion as the materials are suited to the purpose, the design is wise, and the workmanship is excellent. Let it be taken for granted that the materials are suitable, and that the design is that which will survive, and the field will then be free, leaving it open to the discussion of the remaining important question—the methods employed in the manufacturing plant.

It might appear that the remaining main situation allowing that it involves factory equipment is possible of solution on the basis of an abstract problem. A moment's thought must certainly lead to a sound basis for contending that to simply purchase stock machine tools, and place them in orderly array, in a well-designed building, let it be admitted, would hardly do; the tools would not of necessity be suited to the occasion.

An ordinary lathe, while it may be regarded as capable of doing general work at a convenient rate of speed, is entirely too weak to stand up against alloy steel, particularly when the cutting tools are high tungsten product, and the speed of cutting is all the way from 60 to 100 feet per minute. Lathes as they were designed originally, and as they obtain under conventional conditions, are capable of machining cast iron at perhaps 20 feet per minute for the speed of cutting; they will do this work with excellent accuracy, but the tensile strength of cast iron is maximum at 30,000 pounds per square inch, whereas the tensile strength of many of the grades of steel used in automobile work reaches above 80,000 pounds per square inch, and 100,000 pounds tensility is not unusual. In the case of cast iron, the elongation is normal, whereas in the better grades of alloy steel it is not far from 25 per cent. in 2 inches of a ½-inch test proof, and too, account must be taken of the elastic limit of alloy steel. In some of the product this factor reaches as high as 80,000 pounds per square inch, whereas the elastic limit of cast iron is very low.

Obviously, lathes, or in fact any generic type of tool, which may have been designed to handle cast iron, or even the mild grades of machinery steel, as formerly utilized in structural work, are bound to fall below a fitting requirement when high-class automobiles are to be manufactured. Accuracy, while it is necessary in general machinery, is an absolute requirement in automobiles. The old idea was that accuracy depended upon the skill of the man, and it does to a very considerable extent, when the man takes into account the weakness of the tool and by skill limits output to that which will check with the inherent defect in the tools placed at his disposal.

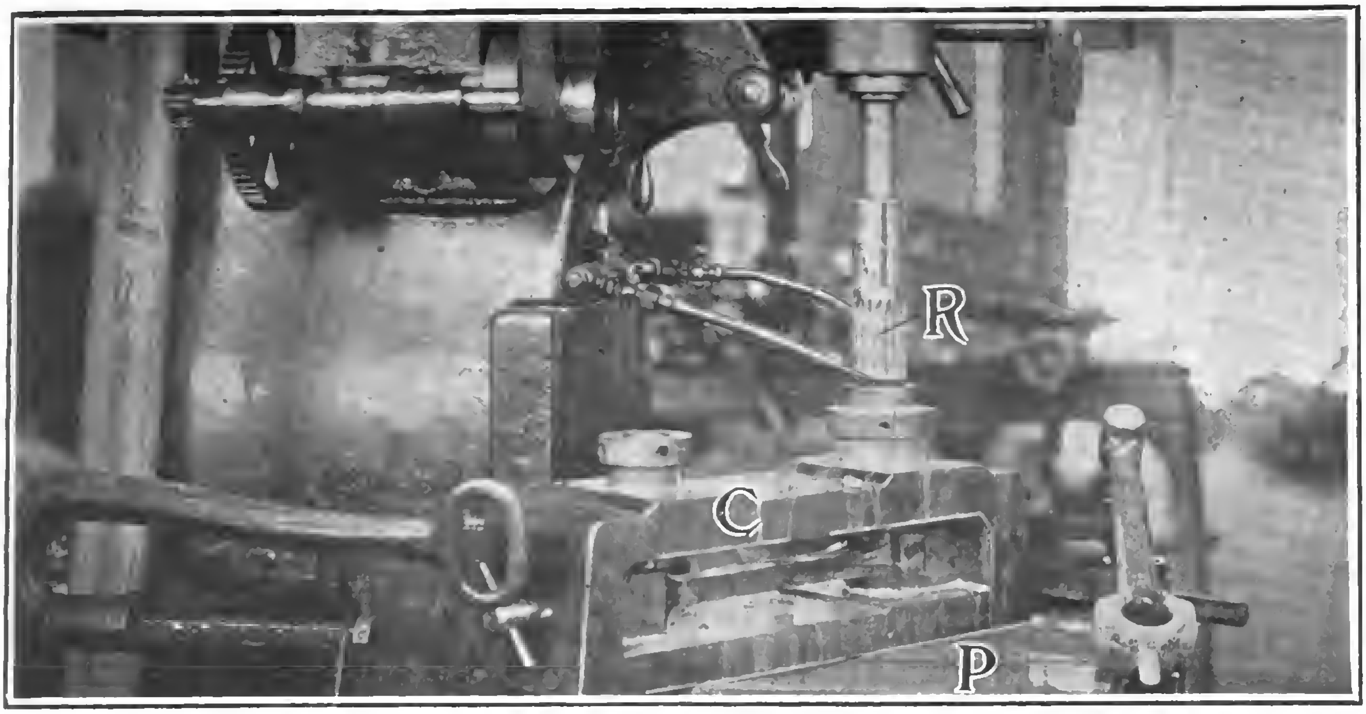
In the early days of the automobile, when ordinary machine tools were all that could be had, men were paid to limit output, and skill on the part of the men was an absolute necessity, because the limit they placed upon the output was that which would induce a measure of accuracy in view of the inherent weakness of the machine tools.

No wise automobile builder will care to go back to the days when skilled machinists were paid to limit the work in proportion to lack of ability of the tools used. No doubt this is an odd way of putting it, but it is in exact accord with the facts as they existed. Automobile work then reflected excess cost and poor workmanship, taking it as a whole. Makers of automobiles were compelled to exact special and more rigid machine tools for the purpose, and in the absence of regular stock products to be had on this basis it became necessary to go in for special machine tools and they, in all probability, considering the respective shops, were designed with a particular eye to the hardness and tenacity of the metal used in the construction of the automobiles.

In the National plant at Indianapolis this phase of the situation was taken cognizance of almost at the start, and the plant equipment is made up very largely of special machine tools, each one designed to do the very work required, and a system of jigs, fixtures, gauges, and instruments of precision is so designed and employed that the antonym of the skill which was formerly sought for on the part of machinists is utilized.

With heavy and well-designed machine tools, fitted with fixtures and jigs, appropriate to the undertakings, skill of the operators is for the purpose of producing the work quickly, a high rate of speed being possible; accuracy is a direct result of the process so that the skill of the workman is not utilized in the act of apologizing for the weakness of the tool.

Fig. 1—General view of machine shop in National Motor Vehicle Company, showing cylinder boring machines working on gangs of engine cylinders. Crankcases are shown in the foreground



No. 2—Fixture used on vertical heavy milling tool to machine connecting rods. The fixture allows the machining of both ends by simply changing the cutter to the proper size

Fig. 1 shows a general view of one corner of the plant with a number of aluminum crankcases in the foreground, and some of the special machine tools in sight. A represents a large and well-designed cylinder boring machine, with a revolving platen on which a fixture is mounted, and the arrangement is such that four pairs of cylinders are in position for work to be done upon them at all times. This type of machine is available for either boring or grinding, and the workman is enabled to swing the platen around as fast as the cylinders are finished, and to replace the finished cylinders with cylinders to be machined as the occasion requires.

In this work the cylinders are rough machined at a high rate of speed, it being the object to remove metal as rapidly as possible, but the final operation, being that of grinding, assures accuracy to the desired limit, and in order to prevent the cylinders from warping in the grinding process, they are maintained at a constant temperature for the time. It is advantageous to rough machine the cylinders at a high rate of speed because the internal strains will be released as the direct result of high speed work, and since the grinding operations take place subsequently, the chances of deformation, due to the release of internal strains, are substantially eliminated.

Referring again to Fig. 1, B presents a multiple spindle tool which is fitted out to do rapid and accurate work on the aluminum crankcases which are of the character shown in the fore-

(*Continued on page* 735)

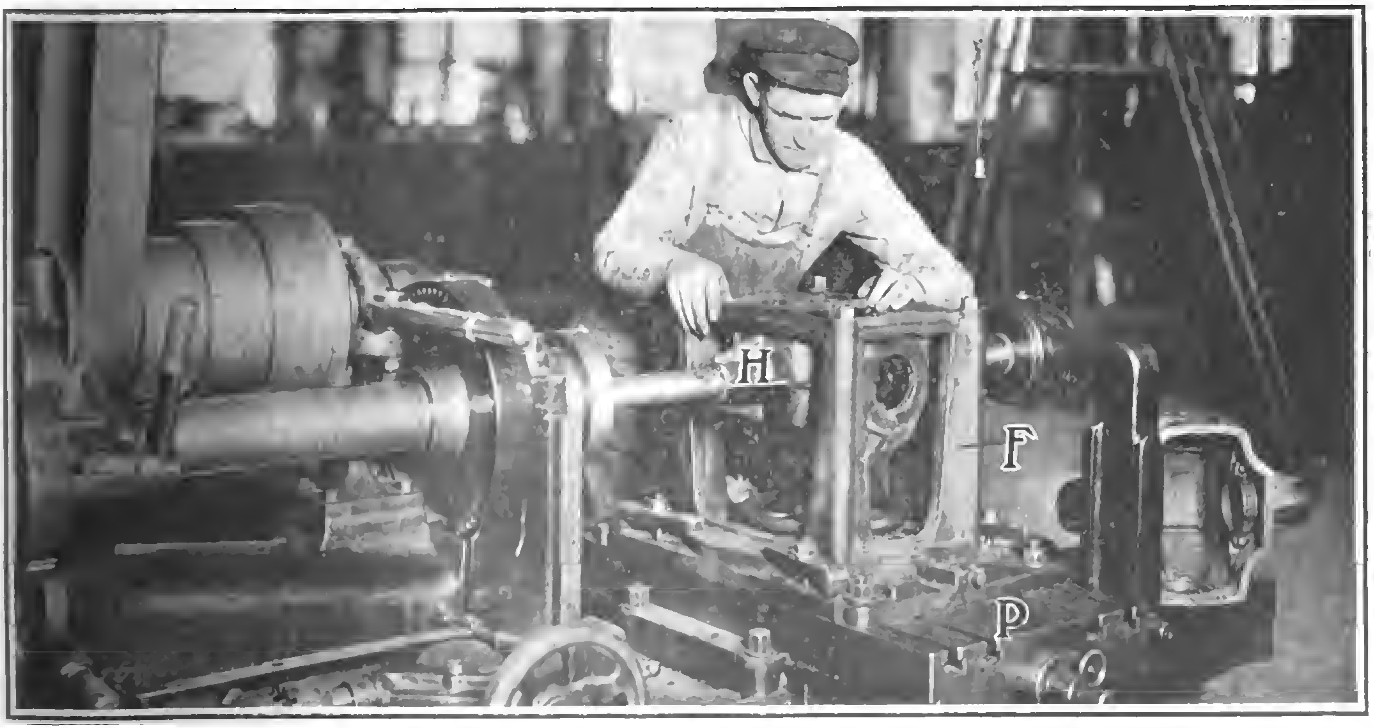


Fig. 3—Horizontal boring machine in National plant working on rear axle and differential housing, the work being held in a special fixture. A finished case is shown at the right

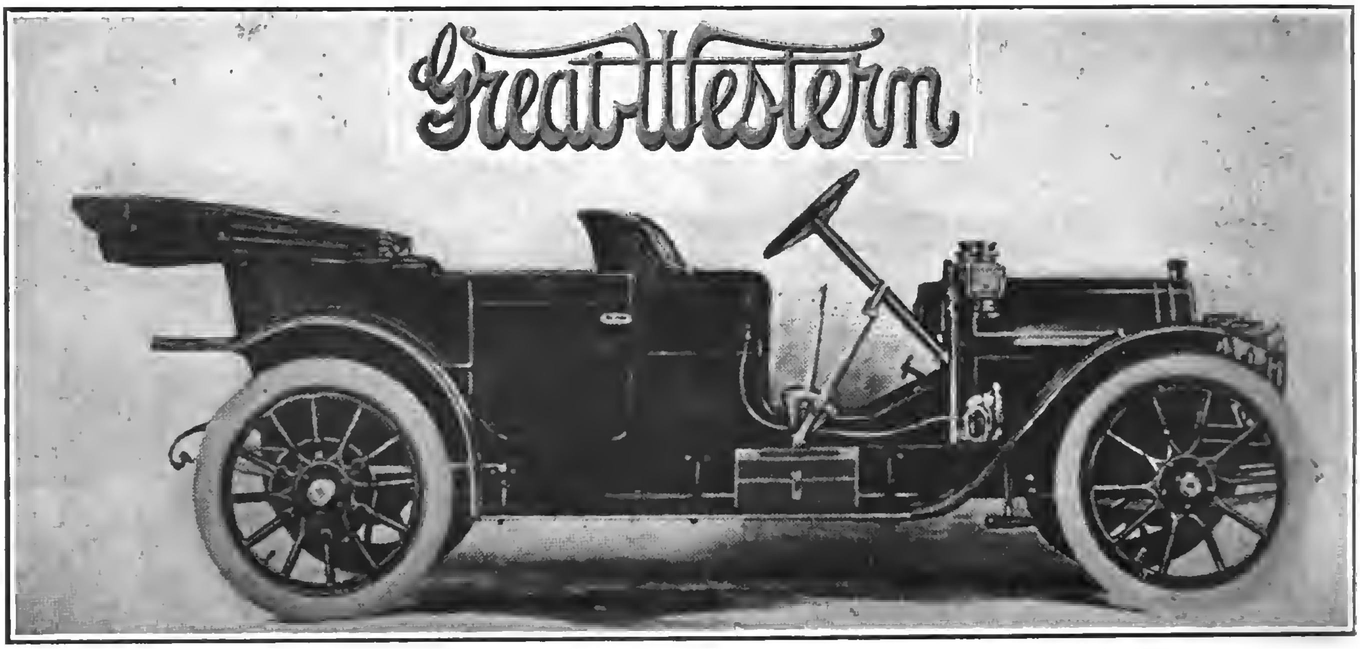
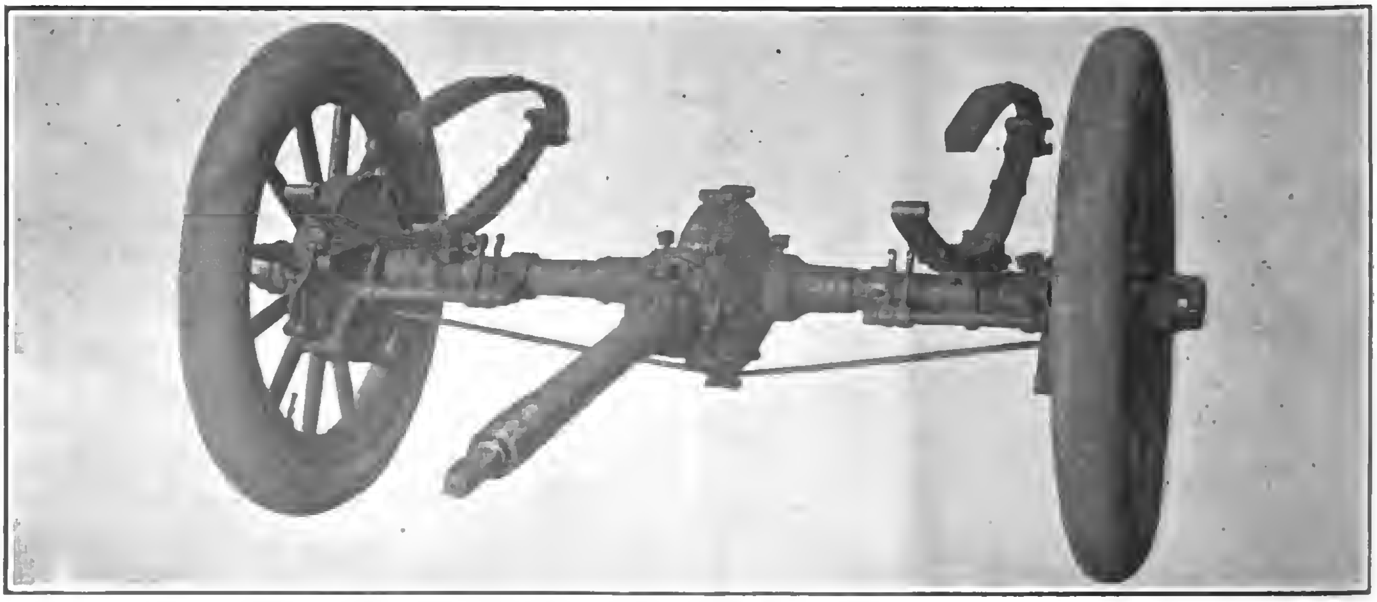


Great Western Thirty With Touring Body Is the Result of Many Years' Experience

FOR 1910 the Great Western Automobile Company, Peru, Ind., previously known as the Model Automobile Company, will continue to build a single type of touring car designated as the Great Western Thirty. This 1910 model has a 4 1-4 by 5-inch motor, with a formula rating of 28.9 horsepower.

Many new features are present in this model, among which are: The enclosing of the timing gears in an oil-tight case, the removal of the magneto from the intake side of the motor to the exhaust side so that the magneto and the water-pump are both operated from the same shaft, and the parts more symmetrically and conveniently placed. This year the fan is supported on an adjustable bracket on the front cylinder; the flywheel is marked for timing; a water-jacketed Schebler carbureter and Remy magneto are regular equipment; and improved water piping is employed in the cooling system. An improved transmission is also claimed for the new model, the gears being now made in the company's factory. The cone clutch is lined with raybestos, with springs underneath to insure easy engagement; and a novelty has been brought forth in the attachment of the pan which hangs under the motor, clutch and gearbox in that it operates on hinges so that it can be lowered by releasing the catches on one side when the car is being washed or adjustments are being made.

The motor is neat and simple in appearance and has a number of the most approved features characteristic of the best modern engineering practice. The four cylinders are cast separately with long spacious waterjackets, the inner walls are ground to the top of the head and the heads are machined to prevent the accumulation of carbon, connections are very direct and quite accessible, all moving parts are adjustable for wear, an absolute interchangeability of parts is claimed, and all outboard bearings not automatically lubricated by the oil circulation in the motor are provided with compression grease cups. The outside features of the motor are clearly shown on the next page. In this, the right side of the motor, the valve mechanisms, which are operated from a single camshaft within the crankcase, may be plainly seen. Note the accessible location of the spark plugs and priming cocks in the intake valve chambers, and the peculiar construction of the intake manifold. This type of manifold construction has been successfully employed by some of the most prominent motor manufacturers. The carbureter, as may



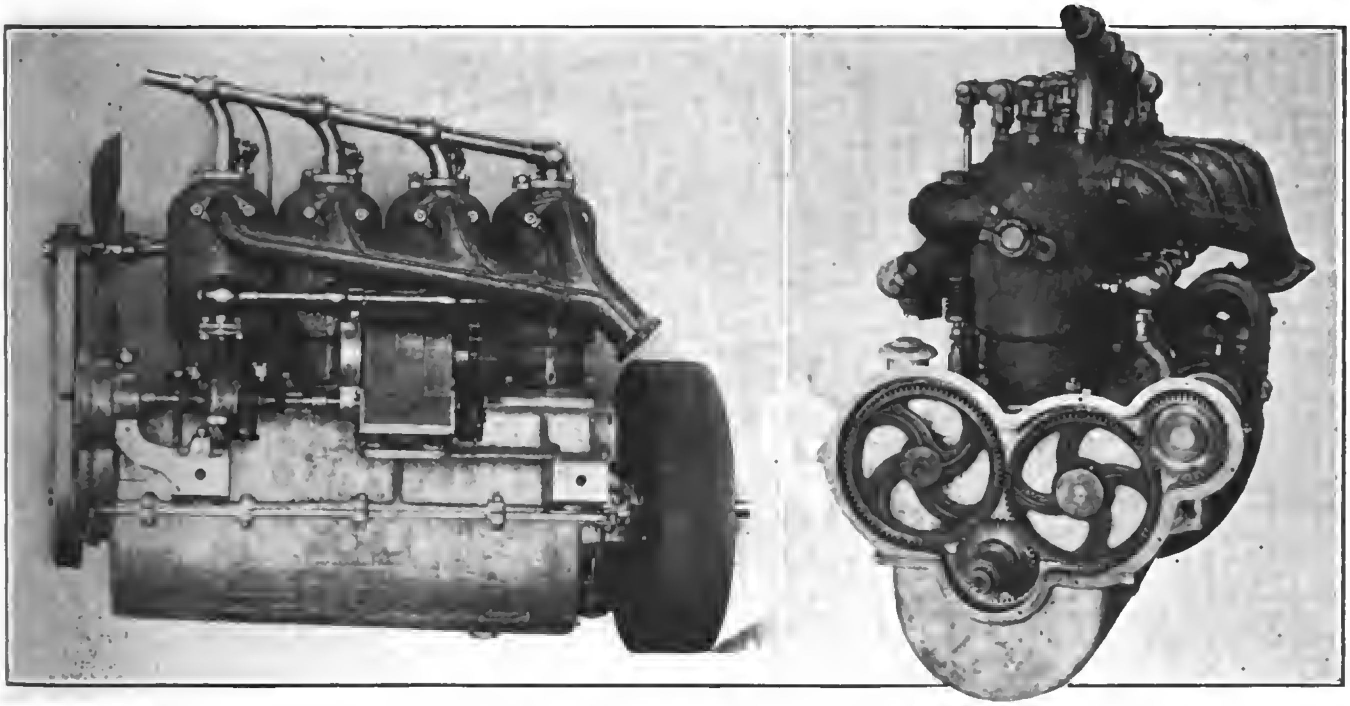
Rear Axle of Floating Type Showing Also Spring Suspension, Driving Shaft, and Wheels be seen, is also accessible, a feature which is greatly to be appreciated by the owner or repairman who has found it necessary on some cars to drop a most unwieldly pan, then try to make adjustments or disconnect a carbureter which is located in a most unapproachable position.

Two large hand-hole plates in the side of the crankcase are provided in order that the contents of the crankcase may be readily inspected; and a vent pipe relieves the crankcase compression. This vent pipe is so constructed that oil cannot possibly be thrown out and yet the compression is released. Between the end of the lower half of the crankcase and the flywheel may be seen the oil pump, which maintains the proper level in the upper portion of the lower half of the case. It is a gear pump, gear-driven off the end of the camshaft through the vertical shaft; and draws the oil from the lowermost portion of the oil reservoir, and forces it into the crankcase proper through the connection.

Turning to the left side of the motor, special attention is called to the construction of the exhaust manifold. It is not only graceful in appearance and easy to remove, but its chief feature is that it has no sharp bends and enlarges gradually toward the rear end so that the gases are so well taken care of that back pressure is reduced to a minimum. The direct connections and rigid supports of the magneto and waterpump are shown in this illustration; the magneto resting on a bracket cast integral with the case, and the water pump bolted to a boss on the leg of the engine. The water, entering the pump at the inlet, passes up into the waterjackets of the cylinders through the manifold, and after circulating around the cylinder walls, valve and explosion chambers, issues from the top of the cylinders and passes to the radiator through the manifold. Each bearing of the shaft which drives the pump and magneto is provided with a grease cup. The metal timing gears are enclosed and run in a bath of oil. The simplicity of the adjustable fan support is also shown in this illustration. Loosening the pinching screw permits the rocking up or down of the bracket to secure the desired tension.

The exhaust valves of this motor are located in the center of the cylinder head, and operated through pushrods and rocker-arms. They are contained in cages and may be readily removed for grinding. The intake valves are contained in outboard chambers characteristic of an L type motor, and operated in a conventional manner from lifters below. All pushrods are adjustable and the entire set may be easily removed for inspection by simply removing the four yokes through which they are clamped down to the crankcase.

All pistons are ground to very accurate measurements and are ribbed for the purpose of reducing weight without decreasing their strength; and to further strengthen their construction and reduce expansion, their heads are convexed. Each piston is annealed to eliminate the unequal strain of the metal when subjected to heat, and then ground to measurement. Four eccentric expansion rings are fitted to each piston and a snap ring is employed to hold the wristpin in place. Oil grooves are also cut into the pistons so that the oil may be uniformly distributed to the cylinder walls, and every piston is machined on the inside to a given weight in order that a replacement may be made without throwing the motor out of balance, should a replacement be found necessary. The connection rods are of drop-forged steel and of I-beam section, with die-cast nickel babbitt bearings at the piston end and split bushings of the same material at the crankpin end. The crankshaft is a solid forging with a flange forged integral with it, to which the flywheel is bolted, and is supported in five die-cast nickel babbitt bearings with a bearing surface of reasonable area. The camshaft, which is supported on three main bearings, is a solid forging with all cams forged integral; and it is so arranged that by loosening the nuts on two of the three bearings the camshaft can be withdrawn. The crankcase is of aluminum alloy, and the motor is so designed that the working stresses of the cylinders do not fall upon the crankcase but are taken up entirely by the steel studs that hold the cylinders and support the crankshaft bearing caps as well.



Exhaust and Ignition Side of Engine, Also End View Showing Timing Gears, Valve Rockers, and Manifold

Transmission from the motor to the rear wheels of this car is conventional in every respect. The clutch is of the regular cone type faced with raybestos, a composition of asbestos and fabric which has been widely adapted as an efficient brake-lining material, and springs have been fitted beneath this clutch facing to facilitate smooth engagement. The change speed arrangement is a sliding gear transmission of the selective type giving three forward speeds and reverse. A locking device is fitted to this mechanism to prevent the gears from sliding out of engagement and it is impossible to bring two sets of gears into mesh at the same time. Drive to the rear axle is by means of a shaft, enclosed in a tubular housing which serves as a torsion tube. The rear axle is of the semi-floating type and the front axle is one-piece nickel steel forging.

Pointers In Repair Work—Referring Specifically to Valves

LAST week in the discussion of the repair of an automobile, it was pointed out, among other things, that the valve grinding process as it obtained through the life of the car had resulted in the valve seats being widened until it became a question as to whether or not tightness could be relied upon. Fig. 1 shows the relatively narrow bevel seats as they obtain in motors when they are new. In some makes of motors the distance across the face of the seat is limited to 3-16 of an inch, and very few motors will be found in which this distance will exceed 5-16 of an inch. Valve grinding has two unfortunate effects, one of which is the face of the seat is increased, and the second trouble is due to the dropping down of the valve to accommodate itself to the new seating, and the timing of the valve is therefore upset because the clearance distance as marked in Figs. 7 and 8 is decreased. This distance may be diminished so much that the valves will not be permitted to seat, in which event they will fail to serve their intended purpose.

Referring to Fig. 2, it will be observed that the seat of the valve is very wide indeed, and this is the condition which was found in the motor referred to above. In this particular motor, the cam wore faster than the amount of the grinding away of the valve seat, so that the clearance, as shown in Figs. 7 and 8, increased instead of decreasing. The result was equally bad, because the timing was upset in any case. It was decided that a good repair could not be realized without reducing the valve seat, and it was suggested that the method as shown in Fig. 3 might be employed to advantage.

Referring to Fig. 3, it will be observed that a wing cutter is inserted in a round hole in a boring bar and the boring bar is then passed through a valve cover opening of the cylinder, after which the guide as shown is screwed down tight in place of the regular cover. It will be necessary of course to slide the guide over the boring bar before the wing cutter is inserted in the hole unless it is found that the cutter can be slipped over from the other end. The length of the wing cutter must be less than the diameter of the valve cover hole, and a measurement must be taken which will permit the repairer to tap the cutter out so that the cutting edge will engage the face as shown by the radius of the dotted line, which is placed to indicate the amount of metal to be removed in the process of reducing the face of the valve seat.

The guide should be quite long, and should extend down in order to support the bar at a point as near the cutter as possible: the larger the bar the less will be the necessity of support. The bar may be driven in any desired way, and a vertical drill press would serve very well indeed. There are certain dangers attached to a process such as this, and Fig. 4 very clearly indicates one of them. It is a well-established fact and known to every foundryman, and those who have to do with cylinders when they are cast from gray iron, that shrink holes abound in the body of the metal wherever it is accumulated, sufficiently to make the rate of cooling lower than the rate in general for the whole casting. The part of the metal which cools off fastest will be the most solid, and it will draw metal from the portions which remain liquid in the process of solidifying. In this way shrink holes are formed and they are very likely to obtain in the metal adjacent to the valve seat unless the design is so contrived as to overcome this difficulty.

In any attempt to re-adjust the seat for the valve, especially if the process as shown in Fig. 3 is resorted to, it will be wise to examine the design and note if there are excesses of metal in the vicinity of the valve seat. If metal obtains there to a considerable extent, there is a good chance of uncovering pockets when the wind cutter engages the metal and takes away any considerable portion thereof. Fig. 5 shows a design which is practically free from trouble of this sort, in which it will be observed that the walls of the forts are not in the same plane as the metal out of which the valve seats are formed. The design has for its basis great uniformity of the thicknesses of the walls throughout, and a further object in thus proceeding is to make the wall thickness back of the valve seat such that water will tend to cool every portion of the seat equally. There are other good teachers to be observed in this design; as, for illustration, the valve stem is in a boss which is water-jacketed for nearly the entire distance, so that the heat which passes down the valve stem from the mushroom is tapped away to the adjacent water, through the stem guide formed out of the boss, which is integral with the metal of the cylinder proper.

It is claimed by some designers that a valve stem bushing is ill advised, on the ground that the conductivity of the joints which form between the bushing and the retaining wall is far below the same property in the absence of joints. The bushing according to this method of reasoning, retards the transfer of heat, and the stems of the valves are then not in a position to tote away the heat which is picked up by the mushroom on the end of the stem, due to its contact at first hand with the flaming products of combustion.

It was observed in the motor which underwent repair, that

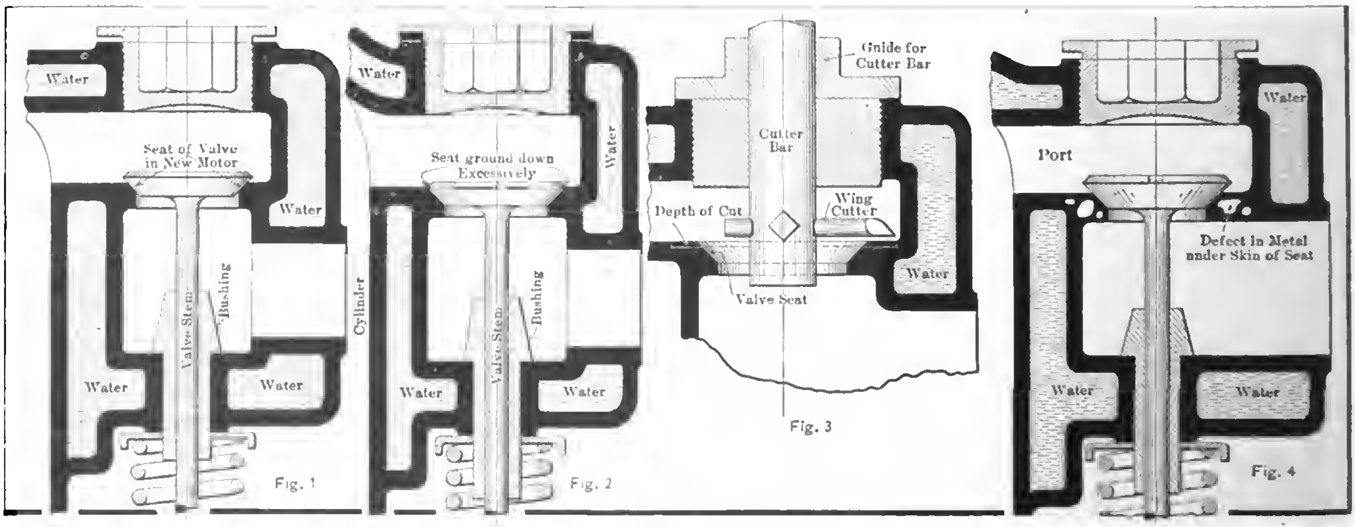


Fig. 1—Showing proper seat as found in new engines. Fig. 2—Condition to be avoided, valve ground down too far into seat. Fig. 3—Wing cutter and guide bar for cutting correct seat. Fig. 4—Unavoidable but troublesome defect in metal just at valve seat

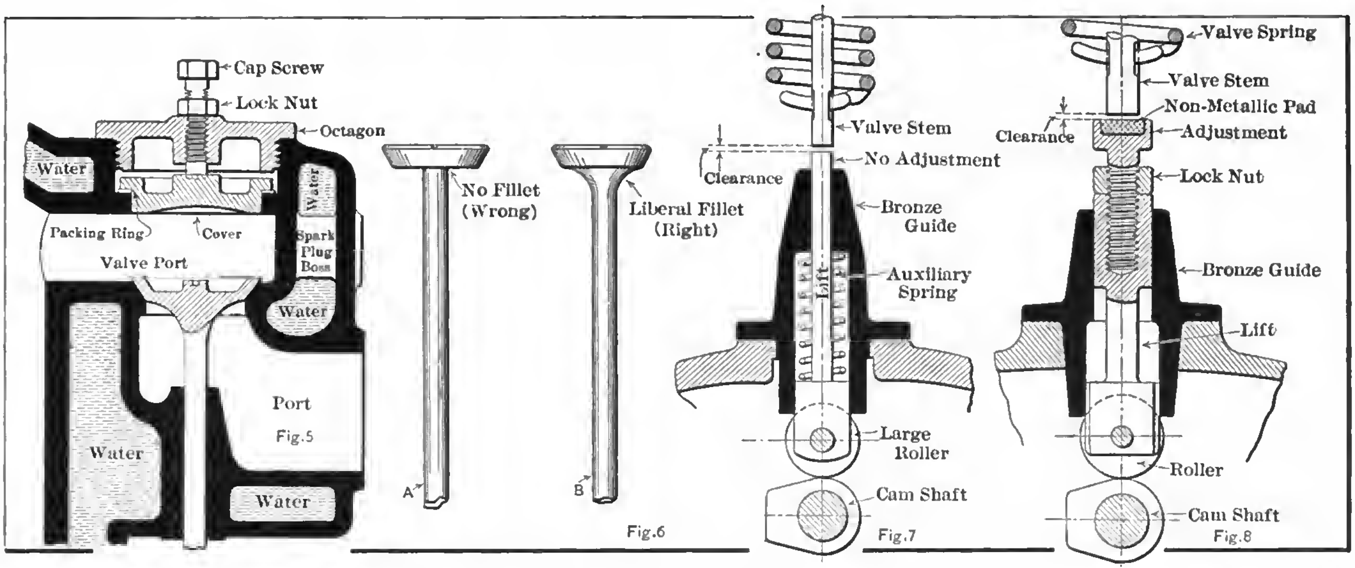

Fig. 5—One method of retaining valve cover in place from above. Fig. 6—Right and wrong way of constructing valves. Fig. 7—Valve construction in which no adjustment is provided for wear, as contrasted with Fig. 8—Proper form of construction with adjustment

the mushrooms on the stems forming the valves were integral, but the joint was made without taking advantage of more than a perceptible fillet. A, Fig. 6 indicates the character of the design, whereas B, is more nearly in accord with the dictates of approved practice. This is an extremely important detail, so it is believed, and tightness of the valves depends upon the rigidity of the relation of the mushroom to the stem. If the point of fastening is only equal to the diameter of the stem, the mushroom will be heated to a very high point relatively to the temperature which will obtain in the stem, so that the stem proper will take on the characteristics of a dog's tail and curl up. The result will be that the stem will stick in the guide unless the guide is provided with excess clearance, and the mushroom will be prevented from lying flat on the seat.

It ofttimes happens that motors perform badly, and credit is given the valves for being mechanically in good order, so that the trouble is blamed on the ignition system or the timing. In divers of these instances, it was ascertained that the valves stuck when they became hot, and the resistance offered was in excess of the ability of the springs. It is not a real remedy to attach stouter springs, and there are disadvantages in so proceeding. The stouter the springs the greater will be the wear on the cam, roller, lift, and the end of the valve stem. If a soft pad is used in the head of the adjusting member, as shown in Fig. 8, it will be pulverized if the spring is too strong; or in the absence of a buffer such as this, the end of the valve stem will broom out. The trouble is due to the curling up of the stem because a means is not afforded for transmitting the heat away from the mushroom, down through the length of the stem, and off to the water jacket, in the manner as before stated.

A very liberal fillet at the junction of the valve stem with the mushroom not only prevents the curling up of the stem by equalizing the temperature throughout, but it also prevents the mushroom from tilting out of its position at right angles to the plane of the stem. There are two reasons apparently for placing a fillet of liberal proportions at the junction, one of which is to impart mechanical rigidity to the mushroom, and its joint with the stem; the other reason is bound up in the greater mass of metal which is available for the transfer of heat. If the maker of an automobile fails to observe these well understood conditions, the repair man, if he appreciates the true situation, is offered a wonderful opportunity to deliver a satisfactory repair and materially improve the actual working qualities.

Should a repair man decide to substitute new valves of his own make for those regularly in use in a given model of automobile, it will be well for him to take into account the proper grades of metal for the intended work. One fabric used for valves is composed as follows:

HIGH CARBON STEEL SUITABLE FOR MAKING VALVES

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.115	.10	.013	.018	.45

It will be understood that these valves will scarcely obtain without variation as between heats, or within adjacent sections in the same bar. Segregation and other variables will defeat the puddlers' attempt, but the carbon should be at least 110 points, and the sulphur and phosphorus should fall below the values given, rather than to exceed them. Manganese and silicon may vary quite a little.

HIGH NICKEL STEEL HAS A WELL-DEFINED VALUE

Nickel	Carbon	Silicon	Sulphur	Phosphorus	Manganese
35.0	.20	.10	.012	.012	.35

Frequently, the high nickel steel mushrooms are attached to carbon steel stems. There is no objection to this if the joint is well made, both from the point of view of mechanical rigidity and in view of the desire to obtain the best heat-conducting ability. The electrical weld seems to be valuable for this character of undertaking, but the welding must be done under the most expert conditions.

When the pressure of the spring is excessive, and the valve stem brooms out in consequence, it becomes extremely difficult to adjust the timing, and a decided loss of power of the motor results. The motor referred to in the repair case was so designed that there was no means of making an adjustment, and as shown in Fig. 7, a large clearance is necessary because the diameter of the roller at the end of the lift as it bears upon the cam is large. An auxiliary spring concentrically related to the lift stem within the bronze guide housing helped to give life to the motion, andto prevent the large roller from bouncing off of the cam. This spring, however, lost much of its life in this service, and offered the further disadvantage of slipping out of place, and in contact with the constantly reciprocating lift, burrowed into the metal. This burrowing process, besides offering evidences of depreciation, also indicated that the motion was not perfectly free to act. A further examination of the mechanism showed that the end of the lift where it engaged the end of the valve stem was broomed out sufficiently to make the clearance in the bronze guide considerably less than that which originally obtained, so that the lift was sticky in the guide.

The repairer wanted very much to attack this problem for the purpose of introducing an adjustment, but the room afforded lent a very uninviting air to the situation, and he finally decided that it was in the path of wisdom to put the parts in good working order, compensate for the increased clearance due to the wearing away of the cam, and take advantage of the fact that the device served for a long time without showing serious

Adjusting the Carbureter—for the Novice

By HERBERT L. TOWLE

IN AN article last week the writer enumerated the four usual adjustments of an automatic carbureter of the auxiliary air valve type. The adjustable elements were as follows:

1. The float valve.
2. The needle valve controlling the spray orifice.
3. The auxiliary air valve spring tension.
4. The auxiliary air valve stop.

As previously intimated, this list varies in different carbureters. The float is always regulated in some manner, but it may be by the crude device of bending the float lever, instead of by a threaded adjustment. Some carbureters have no needle valve in the spray orifice, but instead substitute nozzles with one or another size of orifice to suit different engines. Still others control the size of the primary intake through which air is drawn past the spray orifice. The air valve spring is always adjustable, but the spring itself may be made to act very differently according to the size of the wire, diameter of the coil, and number of turns. When automatic carbureters were new it was not uncommon to find them fitted with springs wholly unsuited to the work in hand, so that the only thing to do was to wind springs experimentally till a suitable one was found. We will first assume that the spring is suited to the carbureter and only needs tension adjustment.

In some carbureters with no needle valve spray adjustment, the auxiliary air valve has two springs, one very light and responsive to slight suctions, the other heavy enough to take care of the suctions due to medium and high speeds. In such carbureters the spray nozzle is correctly chosen at the factory, and the owner adjusts the light air valve spring for low speeds in lieu of a needle valve.

The novice's general instructions for adjusting his carbureter are as follows: Assume that the float valve is correctly adjusted for gasoline. Prime the carbureter, usually by depressing the float, but sometimes by closing a choke valve in the primary air intake to increase the suction. Set the gears in neutral and the throttle valve slightly open and run the engine idle at low speed with retarded spark. Adjust the needle valve, if there is one, otherwise the light air valve spring of the primary air intake, to make the engine run best with the given spark and throttle. Now open the throttle a trifle, allowing the engine to run at about its maximum road speed or a little higher, and advance the spark about half or two-thirds. As the engine is not loaded it will not take much gas, but the auxiliary air valve should open a little. Adjust the air valve spring tension till the engine runs best under these conditions.

Next try the car on the road. Retard the spark and run the car as slow as possible in high gear. Try slightly increasing and decreasing the spray opening and note result. An opening of an eighth to a quarter of a turn of the needle valve is likely to be sufficient. If the engine backfires the needle opening is too small. Be particular to change only one adjustment at a time, otherwise you will not know where you stand. When you get a good adjustment it is well to mark it, so that you can come back to it if an unsuccessful change is made.

Now run the car at medium speed in high gear. Note particularly the pulling power on grades, and the promptness of the response on opening the throttle. If the engine weakens when the throttle is opened it indicates a decided change in the mixture. Try slackening and tightening the auxiliary air valve spring a little and note result. The adjustment previously obtained on the floor should be nearly right, but is likely to need slight changing.

Finally try high speed. If, when running at 20 or 25 miles an hour with the muffler open, the car accelerates smartly on opening the throttle wide, you have a good adjustment. Adjust the auxiliary air valve stop to give a little more or less lift, and note the result. Try slightly changing the spring tension also. Quite likely the same adjustment will not give equally good results at medium speed and high speed. If that is the case, and you do not care to experiment with other forms of spring, it is best to favor the medium speed adjustment as being that most used. Quite possibly a slight further change in the needle valve adjustment may seem advisable. If so, remember that opening or closing the needle valve increases or reduces the gasoline supply throughout the entire range of carbureter action. Increasing the air valve tension, on the contrary, has its greatest effect at

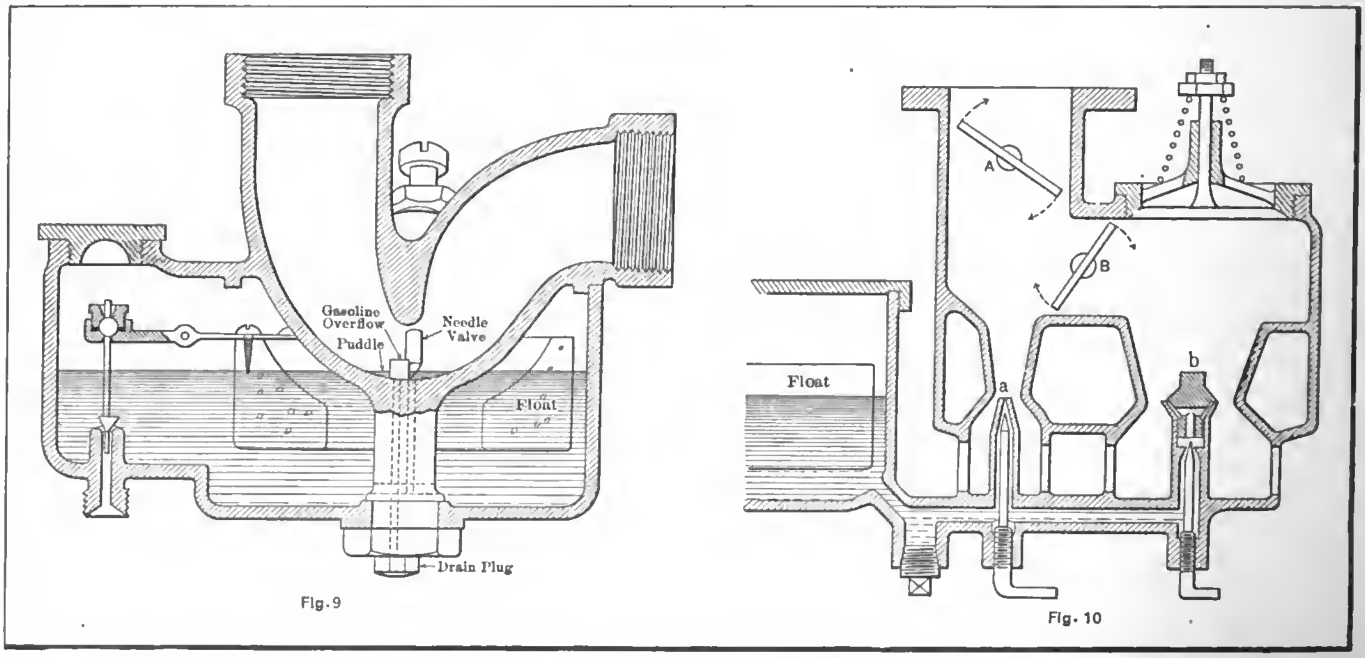

Fig. 9—Typical puddle type carbureter. Either the top or side opening can be used for the outlet. No auxiliary air valve is used. Only the gasoline level and needle valve are adjustable. Fig. 10—Two-nozzle type of carbureter. B remains closed until throttle valve A opens enough to pass as much mixture as the spray nozzle A can furnish.

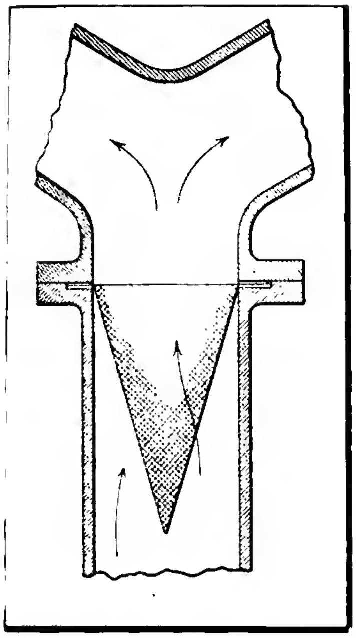

Fig. 14—Gauze cones are sometimes inserted in the intake pipe to break up the gasoline spray

the particular speed or suction at which the valve starts to open, and the effect is relatively less at high speeds. As the spring is always under some initial tension a certain minimum suction is required to start the air valve, and a comparatively slight change in spring adjustment will make a material change in this suction.

In case no combination of needle valve, air valve spring and stop adjustment gives satisfactory results throughout the engine's range, either the carbureter is too large or too small for the engine, or the design is defective at some point. Before abandoning the carbureter it is best to try the effect of changing the spring. To do this intelligently the user must understand something of the action of coil springs. A complete analysis of this subject lies outside the scope of this article, but its most essential points are as follows:

1. The "tension" of the spring (i. e., the force exerted by it under stretch or compression) is the tension of each individual coil composing it, and this tension is directly proportional to the amount that that individual coil is compressed or extended.

2. Consequently, the total stretch or compression of the spring is the strength per coil, multiplied by the number of coils.

3. Inversely, to produce a given stretch or compression, the fewer the coils the greater will be the tension required, and vice versa. To produce a light tension with a given total stretch or compression a spring should have many coils. To produce a strong tension with given compression or extension the spring should have few coils.

4. Extending a spring by merely stretching it has only the same effect as screwing down the retaining nut. It does not alter the character of the spring.

5. A coil with small diameter requires a greater force to compress or extend it than a coil with large diameter, the ratio being inversely as the diameter.

6. The stiffness of the spring is proportioned to the cube of the diameter of the wire.

To show how to apply these principles, let us assume typical cases:

1. Suppose the mixture is correct at moderate speeds, but too lean at high speeds. Adjusting the stop for a smaller lift will correct the trouble if the latter exists only near the limit of speed. If it occurs below the limit of speed the effect of reducing the lift will be to make the mixture again too rich at maximum speeds. This situation calls for a spring which, while exerting some tension at low speeds, has a much greater tension at high speeds. Cut one coil at a time from the existing spring and bend the end square. Adjust to give the same tension as before when the valve opens. The tension at maximum opening will be greater as the number of coils is reduced. If necessary, pull the spring out longer and change the adjusting nut accordingly.

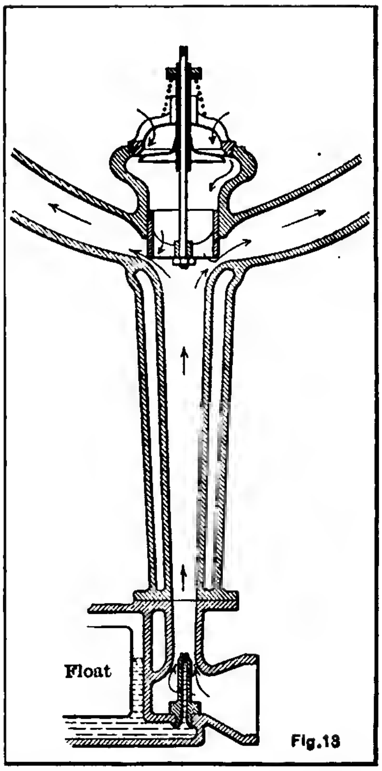

Fig. 13—Carbureter having hot-water-jacketed mixing pipe with throttle at the junction with manifold

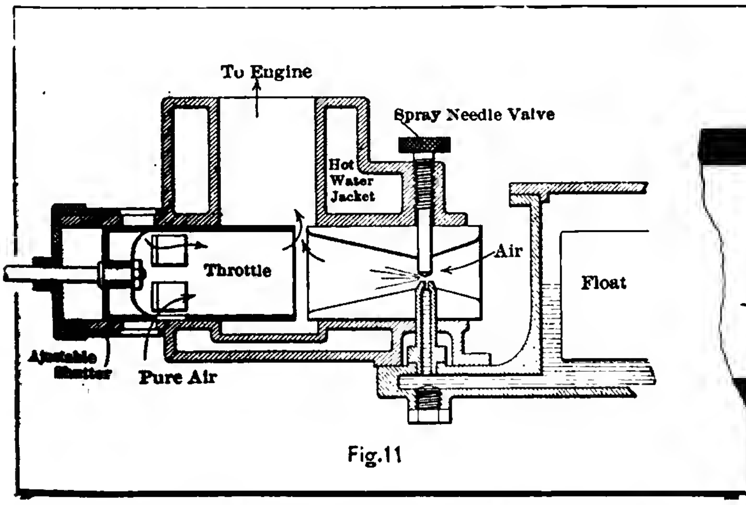
2. Suppose the mixture is much too rich at low speeds, correct at medium speeds and again too rich at high speeds. Probably the spray opening is too large for the engine. Substitute a smaller nozzle if you can. If not, reduce the needle opening, or enlarge the primary air intake so that it is adjustable. If the former is done, the mixture will probably be correct at low and high speeds, but too lean at medium speeds. Increase the tension of the auxiliary air valve a trifle and adjust the stop for a greater lift. Follow the same procedure in case the primary air intake has been enlarged. If the design does not permit any of the above changes, the air valve may have a special light spring for low tensions.

(To be continued)



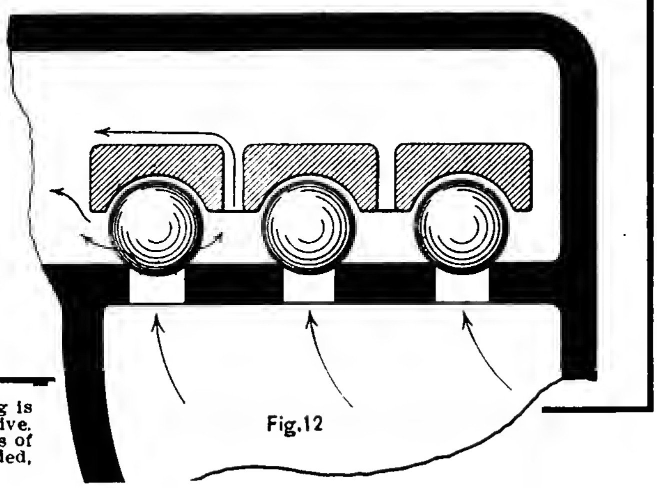


Fig. 11—Non-automatic carbureter, in which the auxiliary air opening is controlled by the movement of the mechanically-operated throttle valve.

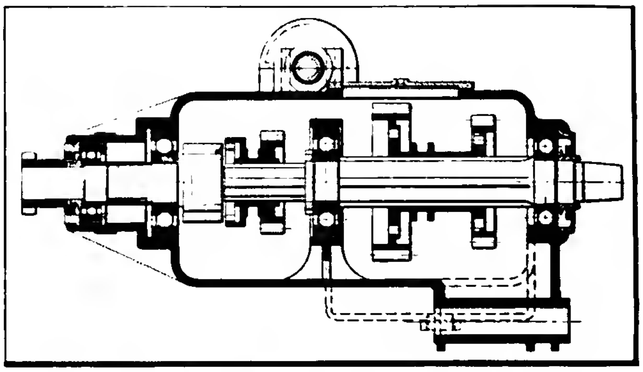
Fig. 12—Gravity seated bronze balls of varying diameter resting on holes of different sizes are used for an auxiliary air valve, no springs being needed, since the suction of the engine uncovers holes of the correct area.

Constructional Details From Engineers Abroad



Protos Change Gear Showing Bearings on Shafts

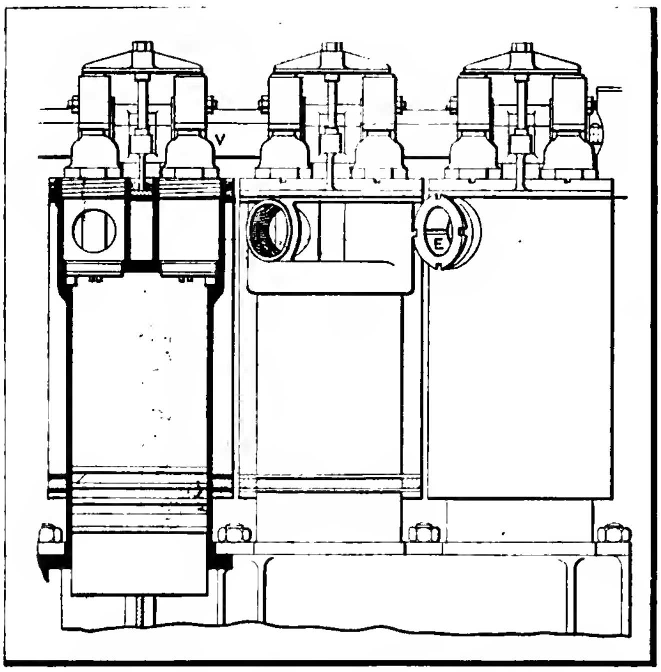
Method of Attaching the Copper Waterjacket

Of the various aeronautical motors exhibited at the recent London aeronautical show none was more favorably received than the Green, an English make with a record of several years' satisfactory service. One point of the motor which few noticed was the method of attaching the copper waterjacket, which is shown by the accompanying drawing.

The cylinders are individual, and the jackets are simple cylindrical copper tubes. At the bottom end of the jacket the cylinder has two narrow flanges, forming between them a groove, in which is placed a gasket or ring of gray rubber. The lower end of the copper jacket is slightly bell-shaped, so that it can be forced over this gasket, the process being assisted by the use of soap as a lubricant. At its upper end the jacket is slightly flanged inward, where it rests on a flange turned on the cylinder head, and is held by a ring clamped by nuts screwing down on the pockets of the overhead valves. The construction can be better understood from a study of the drawing.

Having a sliding joint at the bottom end of the jacket allows a slight movement to compensate for inaccuracies in fitting, so that the upper joint can always be screwed down to a firm seat, and at the same time allow for expansion due to heat. It might be expected that the rubber would be deteriorated by the heat, but it is said that motors of this type have been running for several years without renewals of this part.

The inlet and exhaust ports pass right through the jacket, holes being made in the latter to register with the ports. The manifolds are made with union joints, screwing down to a seat, and the edges of the holes in the jacket act as gaskets for the joint. Thus both the gas passage joints and the gasket joints are made tight at one stroke.



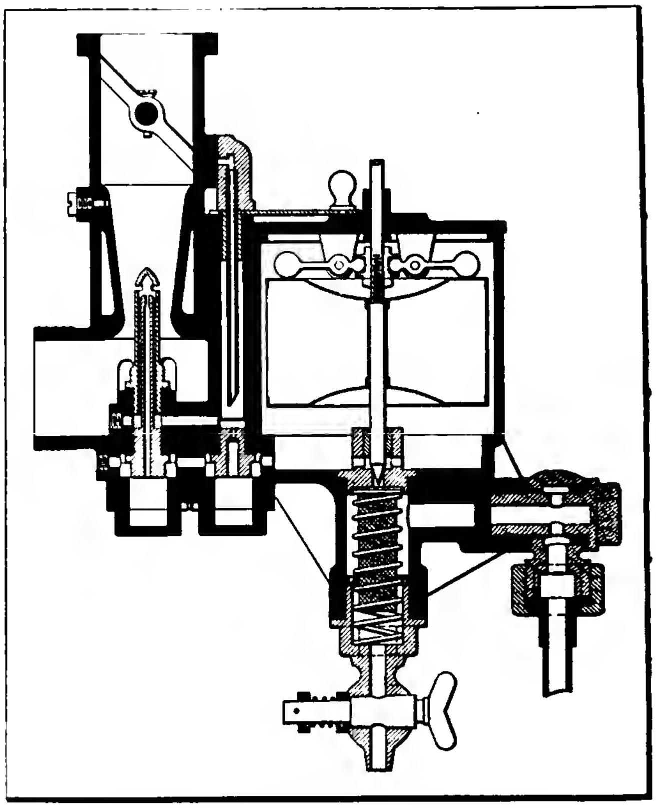
Green Aero Motor Showing Valves and Waterjacket

Overhung Shaft in German Change-Gear

Common practice in the designing of change-gears appears to be to reduce to the minimum the number of overhung shafts, and doubtless this is good as a general principle. Thus the lay-shaft and the sliding-gear shaft are almost invariably supported by bearings at their extreme ends.

On the 18-38-horsepower Protos (German) this principle has been disregarded, and, as it appears, with some reason. It is customary to have one of the bearings of the sliding-gear shaft telescope into the stub shaft which is in line with it; this bearing is either a plain bushing, or else a ball-bearing, the diameter of which is determined not so much by the load as by the space limitation. This bearing often gives extremely unsatisfactory service, and is nearly always the first bearing in the change-gear to wear out.

In order to avoid this construction, the designer of the Protos decided to place the second bearing of the sliding-gear shaft



New De Dion Carbureter on "Zenith" Principle between the two sliding members, in such a way that that part of the shaft carrying the high-speed clutch and the third-speed gear should be overhung. At first glance this design appears only to make a bad situation worse, but a closer inspection will show that the good points considerably outnumber the bad.

When the high speed is engaged the sliding-gear shaft and the stub shaft act as a unit; there is none of the load on the bearing which comes from the thrust of gear teeth. When the third speed is engaged, on the other hand, the third-speed gear lies close against the bearing, and is overhung a distance equal only to its own thickness. In this respect it is no worse than the constant-mesh gear on the stub shaft. Further, the removal of size restrictions permits the use of a large bearing. In this particular case the bearing in question is as large as the main bearing of the stub shaft, and larger than any other in the case. To be exact, the two large bearings are number 408; the rear sliding-gear shaft bearing is number 309, the rear lay-shaft bearing number 406, the forward lay-shaft bearing number 308, and the forward stubshaft bearing number 307.

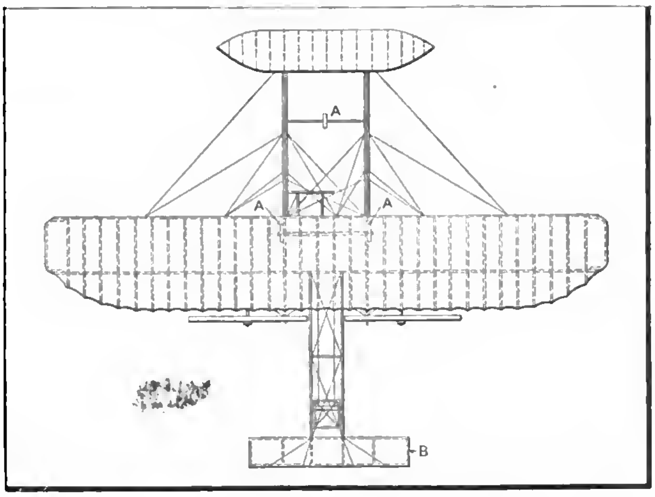
De Dion Adopts New Carbureter Principle

Multi-jet carbureters are far from novel, but most devices of this type have the jets arranged in a row, with some mechanical means for bringing them into action in succession. The carbureter adopted by De Dion-Bouton for its 1910 models, working on what is known as the "Zenith" principle, has its two jets concentric. The general arrangement is shown by the sectional drawing reproduced from *The Autocar*.

The automatic action of the carbureter is due to the limitation in the speed of the gasoline flow to the outer of the two concentric jets. The float chamber supplies both jets, but, whereas the gasoline reaches the central jet through large channels, the supply to the outer jet is limited by the small orifice through which it must pass. Between the float chamber and the central jet there is a cylindrical chamber open to the air. When at rest, the gasoline rises in the two jets to the same height.

At slow speeds gasoline is drawn from the two jets in about equal proportions. In a single-jet carbureter the proportion of gasoline to air increases with the speed at which the air passes the jet; but in this type the output is in correct proportion at all speeds, because the supply from the jet remains constant.

In the cylindrical chamber between the float chamber and the central jet is a small tube, the upper end of which connects with the inlet pipe just at the throttle valve. The valve is arranged so that when it is nearly closed all the mixture that passes through must go directly over the end of this tube. The air passes at high speed, even when the engine is turning slowly, so that gasoline is sucked up through the tube. This additional supply greatly facilitates starting the engine, and makes priming unnecessary: it also allows the engine to be run at very slow speeds.

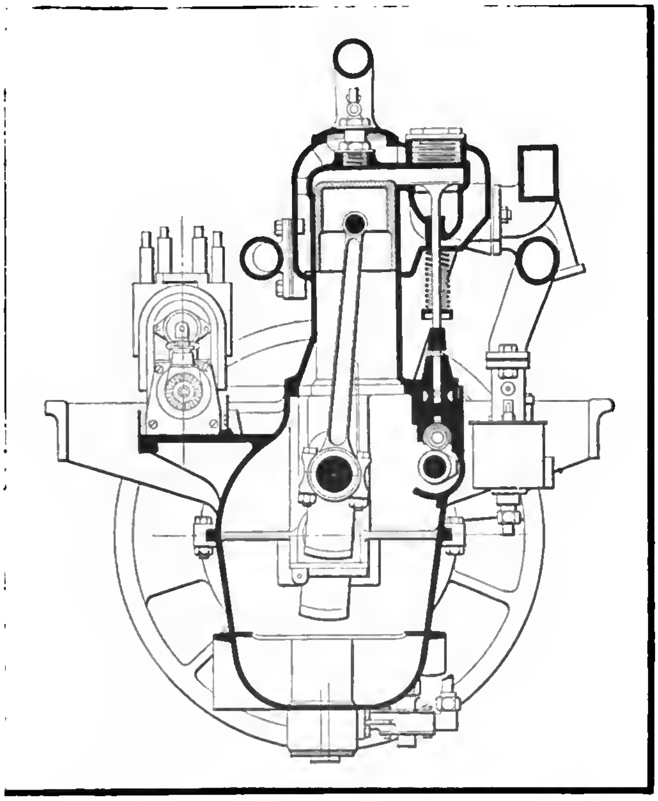


Plan View of Wright Biplane Showing Wheels and Tailplane

German Wright 'Planes Have Wheels

All the Wright aeroplanes made by the Deutsche Wright Gesellschaft will henceforth be fitted with wheels and tails, according to the *Automobil-Welt*. The accompanying drawing shows the new machines in plan view. The wheels are three in number, and are attached one to each of the two skids, just under the front edge of the planes, and one forward of these, attached to a cross-member. It has been found that with these wheels the teaching of purchasers to operate the machines is much simplified, as the beginners can make short flights on their own account without using the starting derrick.

The dimensions of the aeroplanes being built by the German company are given by *Automobil-Welt* as 12.50 meters wide, 9.50 meters long and 2.75 meters high, mounted on wheels. The main planes are 12.50 meters across and 2.00 meters deep; the forward horizontal rudder is 4.65 by 0.95 meters; the propellors are 2.60 meters in diameter. Improvements in the motor have reduced the weight from 108 to 95 kg., increased its output from 28 to 33 horsepower, and at the same time reduced the gasoline consumption from 400 to 290 grams per hour.



Cross Section of Metallurgique Motor Showing Offset

Unusual Amount of Cylinder Offset

Offsetting the cylinders from the crankshaft is a recognized and legitimate practice in automobile design, but few designers have dared to go to the length shown in the accompanying sectional drawing of the motor of the Metallurgique (Belgian) 12-14-horsepower car. Although no exact measurement of the offset can be found, it is apparent from the drawing that the amount is nearly half the cylinder bore. The motor in question has a bore of 75 mm. and a stroke of 110 mm. (approximately 2.95 by 4.33 inches). Thus the offset is approximately 1 1-4 inches for a 4 3-8-inch stroke. This motor also has the valves slightly offset from the camshaft. It will be noticed that the designer has found it necessary to spread out the lower part of the cylinder bore to give the connecting rod free action.

Baratoux, *Wright*, Warping His Planes

Henry Farman on His Latest Biplane

Seen From Henry Farman's Biplane

Riemsdyk, *Curtiss*, in front of Grand Stand

Sands, *Antoinette*, competing for Distance Prize

CANNES, FRANCE, Mar. 28—Never has an aviation meeting been heralded by such a fine series of performances as were shown here yesterday. All the flyers were in the air, doing their utmost to beat their rivals, with the result that many flights of over an hour's duration were accomplished. The only accident of the day befell Molon, one of the favorites. On his Blériot he was the first away, quickly joined by Christiaens on his Farman. For some time the two raced with each other, until at one of the corners, when Christiaens was overtaking his rival, there was a miscalculation by one or the other, which resulted in the monoplane being thrown off the course and landing in an adjacent field. Molon was unhurt, except for a cut on the face, but his machine was badly damaged. Later in the day, however, he made his appearance on another machine and succeeded in covering several laps.

The meet was organized by the city of Cannes, under the patronage of the Aero Club of France, and the different events are held under the rules of the International Aeronautic Federation. The prizes amount to a total of 100,000 francs. Among the more important of the events scheduled are the prizes for first laps, which are rewards of 500 francs for each of the twenty aviators first to make the circuit of the course; the prizes for the longest single flights, amounting to a total of 10,000 francs; the grand prize of Cannes, for greatest total duration of flights by a single aviator, and a prize of 20,000 francs for the winner of a cross-country flight of 19 kilometers over a specified course.

Most of the competitors who have engaged their entries are comparative novices; but nothing could better show the ease with which the new sport is learned than the excellent performances these same novices made. Farman biplanes, of the type made familiar in America by Paulhan, appear to predominate; they are used by Frey, Christiaens and Edmond, all promising drivers. Molon uses the Blériot monoplane; Hayden Sands, the American, drives an Antoinette monoplane; Baratoux has one of the French-built Wright machines, which has been fitted with wheels in addition to its skids, and Riemsdyk handles a Curtiss biplane, the only American-built machine to appear.

Henry Farman's new biplane has received much comment, favorable and otherwise, although no one doubts that this pioneer knows what he is about. The peculiarity of his latest machine is that the upper plane is wider than the lower, having five panels to three in the lower plane. The overlapping panels of the upper plane alone are provided with the hinged flaps for maintaining lateral equilibrium. On one of his flights in this machine Farman took up a photographer as passenger, securing some very interesting views.

Another clever photograph was secured of Baratoux' Wright machine making a turn and in the act of warping its wings. The increased curvature of the planes on the depressed side of the machine is clearly visible, as well as the flatter shape of those on the raised side. Baratoux may also be seen with his right arm extended to work the lever producing the warping.

Aeronautic Progress Along Constructive Lines

By MARIUS C. KRARUP

AVIATION is an art so young that intuition and invention play a greater part in solving its problems than science and engineering. Its data are insecure and scattered. Even in the fundamentals, there is more to be learned than has been learned, and probably a good deal to be unlearned. By a systematic and orderly discussion of aeronautic construction, which it is proposed to inaugurate in these columns, it should be possible to advance the art and concentrate inventive energies, as well as public appreciation, in channels where these important factors in new work will do the most good. But before proceeding to this orderly discussion, the unsettled condition of all knowledge on the subject makes it desirable to throw out feelers first in order to ascertain the present state of mind of all those most vitally interested in aviation matters, so that material may come to hand showing on what particular phases of the subject strong differences of opinion exist and where the center of interest is located. With this object in view, a number of assertive statements are presented in the following without proof or discussion, and dissenting opinions are cordially invited from readers who fail to agree with the statements made. Subsequently, in the more orderly but also more lengthy discussion, those portions of the subject on which most vital dissension exists, or which most keenly engage the interest of the workers in the new art, will then be treated most promptly and elaborately in text and sketches.

In horizontal aeroplane flight no power is spent in overcoming gravitation; all the power delivered by the propellers is completely used up in overcoming air resistance. Gravitation need not be overcome by a flying machine any more than by an automobile. It is the peculiarity of aeroplane action that it renders the atmosphere momentarily as unyielding under the surfaces of the aeroplane-machine as a hard road is under the wheels of an automobile. The less perfect aeroplane meets more air resistance, other things equal, than the better one; much as the poorly constructed automobile has more friction, of various sorts, to overcome than an automobile of higher grade and quality. There is a close analogy between air resistance in fliers and friction in automobiles, but the aeroplanc constructor has the advantage that, when he improves his planes, he improves the road at the same time, because the plane makes its own road, as it flies, while the automobile builder must take the road, as he finds it. At present, planes adapted for fast flight differ in shape from planes best adapted for slow flight, but this is a shortcoming based upon faulty understanding of aeroplane action, faulty construction and the lack of suitable aeronautic materials. Machines can be built suitable for all speeds.

If the air resistance against the propulsion of a machine at the lowest speed at which it can fly equals $R+r$, in which R stands for the resistance against the propulsion of the supporting surfaces and r for the resistance of stanchions, body of aviator, engine, radiator, front edges of planes and other non-supporting parts of the machine, the air resistance at doubled speed and the same load will be $R-x+r^{2+}$; hence the extreme value of redncing r to a minimum. But if the load is doubled as well as the speed, the resistance will be in the form of $(R-x)^{2+}+r^{2+}$. The x is a small value compared to R and depends on the increased efficiency of a properly constructed plane when worked at small tilts. The exponent $^{2+}$ indicates that resistance increases somewhat faster than the square of velocity.

The curve of an aeroplane serves the purpose of establishing a cushion of somewhat compressed and somewhat confined air between the plane and the free atmosphere, thereby retarding the yielding of the latter, preventing the formation of eddies under the planes and contributing to an equable distribution of pressures. The curve is destined to be superseded by other means for accomplishing the same purposes. Among these means will be the introduction of flexibility and resiliency in large portions of the planes and the contrivance of compartment air pockets under those portions of the planes which remain rigid. These improvements are absolutely necessary for the automatic balancing of aeroplane machines in gusts of wind, but will also greatly increase the cost of their construction.

The cheap aeroplane is doomed. The irregular movements of the atmosphere are as fatal to a frail rigidity maintained by means of guy wires or steel tape as the unevenness of roads was to early automobiles with angle-iron frames and a rigid suspension of parts, forming a construction in which the most severe shock always found the weakest spot for its attack, by natural selection.

The efficiency of the power thrust from propellers in all present-day biplanes and monoplanes varies with the tilt of the planes in flight, and the tilt varies according to load and speed (speed always considered and measured in relation to the enveloping atmosphere). The power works directly in line with the resistance to motion only at one certain tilt for each machine. The tilt should be adjustable with relation to the direction of the propeller shaft and the whole power plant and the payload.

Other losses in power application are much larger. More than fifty per cent. of the engine power is wasted in setting up centrifugal stresses in the propellers. Hence the choice of four-bladed propellers by many French constructors, the small rotary velocity of the Wright propellers, the pointed ends of Cody's propeller. But more efficient improvements are needed.

If one propeller of seven feet diameter calls for thirty horsepower in order to be rotated at one thousand revolutions per minute, and wastes eighteen horsepower in centrifugality, five in friction and misdirection of thrust and delivers seven in useful propulsion, and another propeller of the same dimensions and shape is constructed so as to require sixty horsepower in order to be rotated at the same speed and pitch, the loss in centrifugality will be the same as in the case of the first propeller and the direction of forces will be the same. In the first case there was twelve horsepower left for thrusts against the atmosphere; in the second there is forty-two, which, divided in the proportion of five and seven, leaves twenty-four and one-half horsepower—available for useful propulsion. To accomplish this improvement in efficiency and applicability of high powers is plainly within easy range of mechanical feasibility, by compelling the atmosphere itself to produce the required pitch against a resilient resistance in the propeller, as the birds do with their wings and the fishes with their tails.

Four-bladed propellers should lose much of their efficiency in the higher strata of the atmosphere—where the pressure of the air column is smaller—and, as flying machines will be required to pass over high mountains as well as out of cannon range, two-bladed propellers placed tandem give more promise.

A headwind acting horizontally does not reduce the power required for flight but permits the aeroplane to rise more steeply, both from the ground and when in the air.

Kite action is less efficacious than aeroplane action. This has been observed by the Wrights and is explained by the fact that the whole atmosphere moves under the kite—or under the aeroplane held by power in the teeth of the wind—while the aeroplane propelled through a calm atmosphere meets an extra resistance and derives an extra support from driving the layer of air directly in its path against the quiescent air underneath.

The same cause makes aeroplane action somewhat more effective near to the resistant earth and supplies an explanation, when none better seems available, for the failure of many amateurish machines, in not leaving the earth more than a few feet, moving in a series of hops and bounds.

(To be continued)

Recent Trade Publications

Prominent on the first page of the American Locomotive Company's catalog is the famous Vanderbilt Cup, now in the possession of this company, and the idea is carried through the entire book by miniature drawings of the cup appearing beneath the trade name "Alco" in the corner of each page. The cover is in heavy linen paper with the design stamped in without the use of color, producing a distinctive effect; the design includes the word "Alco" and the outline of a touring car, behind which looms the dark shadow of a locomotive. It is a very creditable piece of work. There are 35 pages of text and illustrations devoted to the car which "stays new," both in touring, taxicab and commercial models.

More fully to set forth the lines and colorings of the Chalmers models, the catalog of the Chalmers Motor Company, of Detroit, is provided with half a dozen separate colored illustrations, on heavy cardboard, contained in a pocket on the back cover. Each of these shows some one of the Chalmers models in a coat of different hue—one in thistle green, one in red, one in hazel brown, one all in blue, one in blue with cream wheels, and one in blue with red striping. The catalog proper has 32 pages of good size, with clear-cut half-tone illustrations, and text in the well-known Chalmers style, which is good reading and at the same time instructive to technical man and novice.

Between covers of soft, heavy paper stamped with a gold design, the Anderson Carriage Company, of Detroit, sends out 55 pages of description and illustration of the Detroit Electric. The matter is arranged in a novel fashion. Every alternate pair of facing pages has on the left a picture of one of the Detroit models, and on the right the specifications of that model; the other pairs have on the left a photograph of the model of the preceding pages with some attractive detail of setting, or a view in the Anderson factory, and on the right a brief story of some of the cars' accomplishments.

As the original and native American, the catalog of the American Motor Car Company, Indianapolis, bears on its cover a portrait head of a pretty young lady in the aboriginal headdress, no doubt the forerunner of the only too familiar "peachbasket." The catalog contains four full-page plates of the different American models, in which the car is printed in black and the landscape background in a warm brown ink. The latter is also used for decorative borders on the other pages. The mechanical illustrations are especially commendable, there being an abundance of both general and detail views.

Shaft drive for electric cars is the chief talking point of the Baker Motor Vehicle Company, Cleveland, O., and its advantages are well set forth in a handsome catalog of 32 pages issued by that company. A cover of stiff grey paper with a design stamped in blue, black and gold forms, the outer dress, and within the various models are illustrated and described in an attractive fashion. The Baker line is unusually complete, including an even score of models, of which thirteen are shaft-driven; the prices range from $850 for a runabout to $3,500 for the landaulet and brougham.

"Buick 1910 Specifications" is the title of a small but well filled book issued by the Buick Motor Company, of Flint, Mich. It is printed on rough paper in two colors, line cuts being used only. The plan is followed of having a side elevation drawing of the car on the left-hand page, and its specifications, in a compact form, on the right. Seven different styles are shown, these being the two-cylinder model F, the four-cylinder model 10 as roadster, surrey and baby tonneau, model 16 as roadster and touring car, and the new model 17.

Two-cycle motors are steadily overcoming the prejudice opposing them, and the catechism contained in the catalog of the Atlas Motor Car Company, of Springfield, Mass., will go a long ways towards giving the final conviction. In the question and answer form, this expresses in popular language the advantages of the two-cycle construction. The catalog is unpretentious in comparison with some of the recent high art effects, but contains much real information, which, after all, is what the prospective purchaser wants.

The "Columbus Red Book," as might be expected, is the catalog of the Columbus Buggy Company, Columbus, O., devoted to that company's electric vehicles. The covers from which the catalog takes its name are a rich, dull red, and enclose 24 pages of medium size. After pages setting forth the advantages of the electric automobile, and describing the special features and advantages of the Columbus, follow photographs and specifications of the seven different Columbus models.

Striking in appearance is the catalog of the Black Mfg. Co., of Chicago, describing its Black-Crow cars; the sheet size is unusually large, and it is bound in covers of one of the new pastel shades of reddish brown, with the caption "1910 Black-Crow" in black. Although the pages number but 16, their size enables them to carry an ample amount of descriptive text, as well as large and clear illustrations. The text is particularly commendable in its accuracy and detail.

Dorris cars for 1910 are described in a catalog of convenient size. The pages are given a distinctive touch by a half-inch border of grey: those on the left hand carry illustrations of the cars and their parts, and are faced by pages of descriptive type. The full-page plates show the front and side views of the standard touring car, the chassis in plan view, the roadster and the limousine. The catalog is issued by the Dorris Motor Car Company, St. Louis.

Bailey electric vehicles are described in a neat booklet being sent out by the S. R. Bailey Company, Amesbury, Mass. The Bailey phaeton has particularly graceful lines, the frame being curved to correspond with the body design. This has the additional advantage of bringing the weight low. With the catalog comes a folder entitled "an appreciation," in which a prominent automobilist, who has owned 28 cars, tells what he thinks of the Bailey.

"Built and tested in the Berkshire Hills," can mean only the Berkshire car, the product of the Berkshire Auto-Car Company, of Pittsfield, Mass. The reading matter is reprinted from a trade magazine, and describes the car in considerable detail, in such manner that the technical man will find much value in it. On the inner back cover the specifications are summarized.

"Automobile Components" is the title of catalog G, from the Briscoe Manufacturing Company, of Detroit, Mich., and Newark, N. J. Besides illustrating the four or five principal plants of the company, much space is given to the square tube and tubular radiators, as well as the sheet steel products, which include hoods, fenders, fender fasteners and irons, drip pans, tanks, tool boxes, mufflers, steering wheels, and many other accessories.

Making a Demonstration

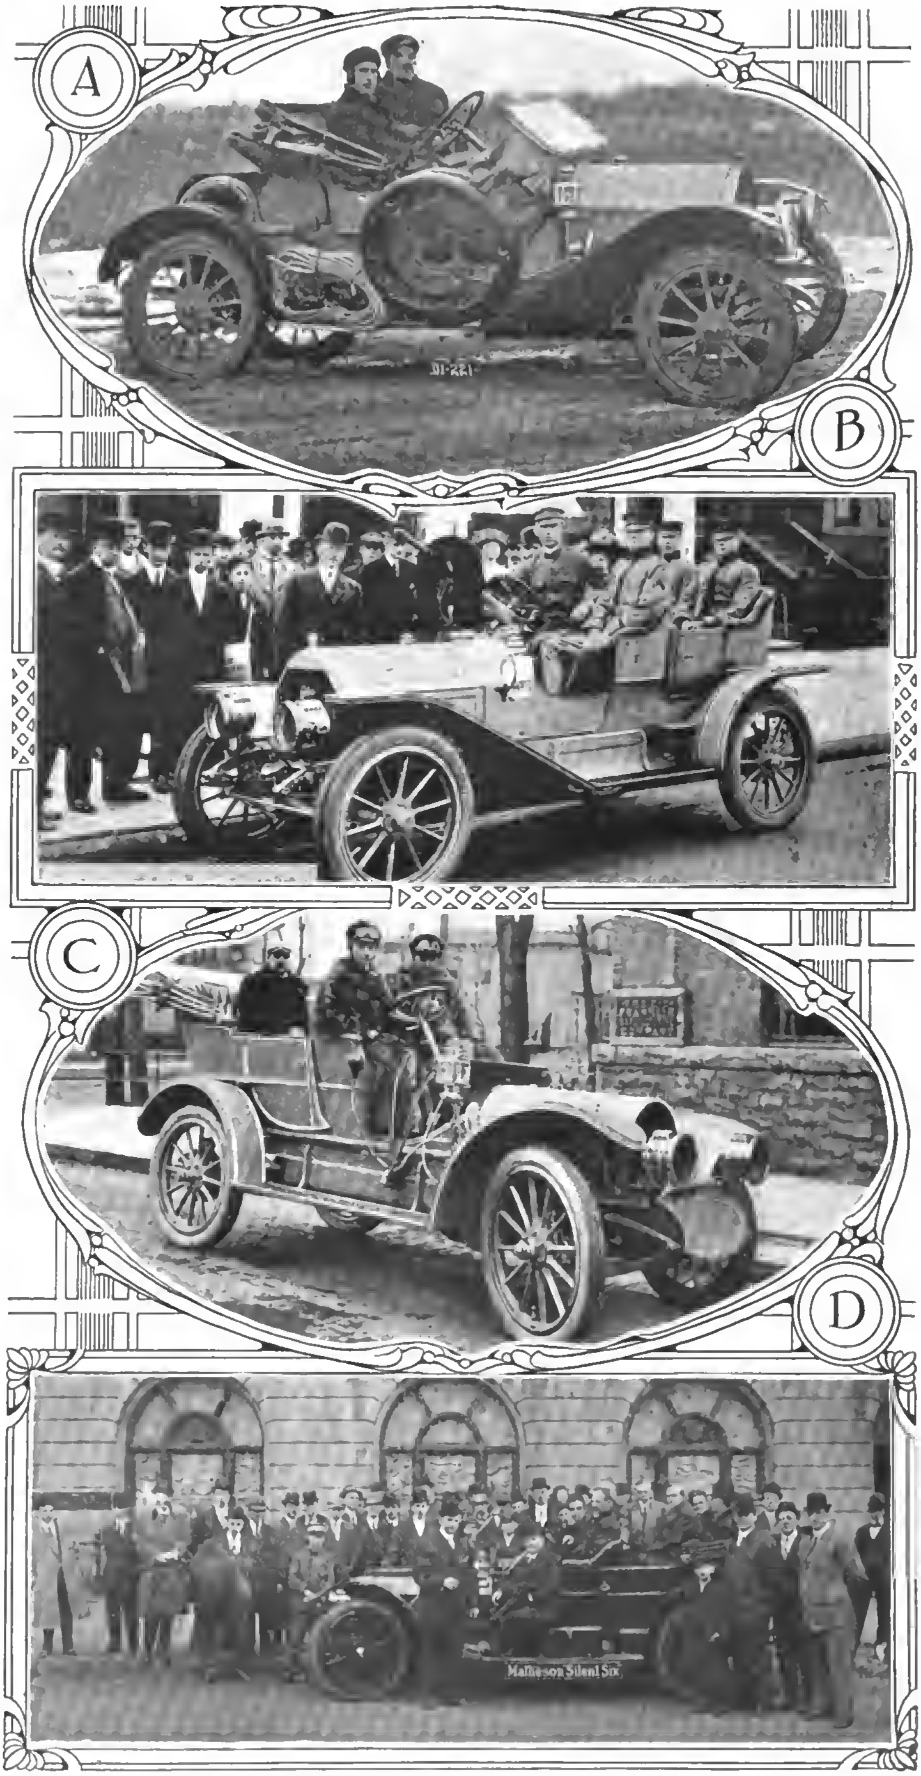
DEMONSTRATIONS are not alone the daily work, the source of bread and butter so to speak, of the agency and garage men, but are also closely interwoven into the work of the second-hand dealers, and a part of the routine work of the factory testers. This makes the subject of wide interest.

(A) Hudson runabout which has just completed a trip from Detroit to San Antonio, Tex., with the equipment which was carried along and which carried the car through many dangerous spots on the Western desert, in the alkali country and elsewhere. This trip was made in the dead of Winter, so that the perils of the road were greater than would be the case to-day. The long drive consumed four weeks, during which time J. S. Mohrhardt and Freeman Monroe, of Detroit, put in a very strenuous time.

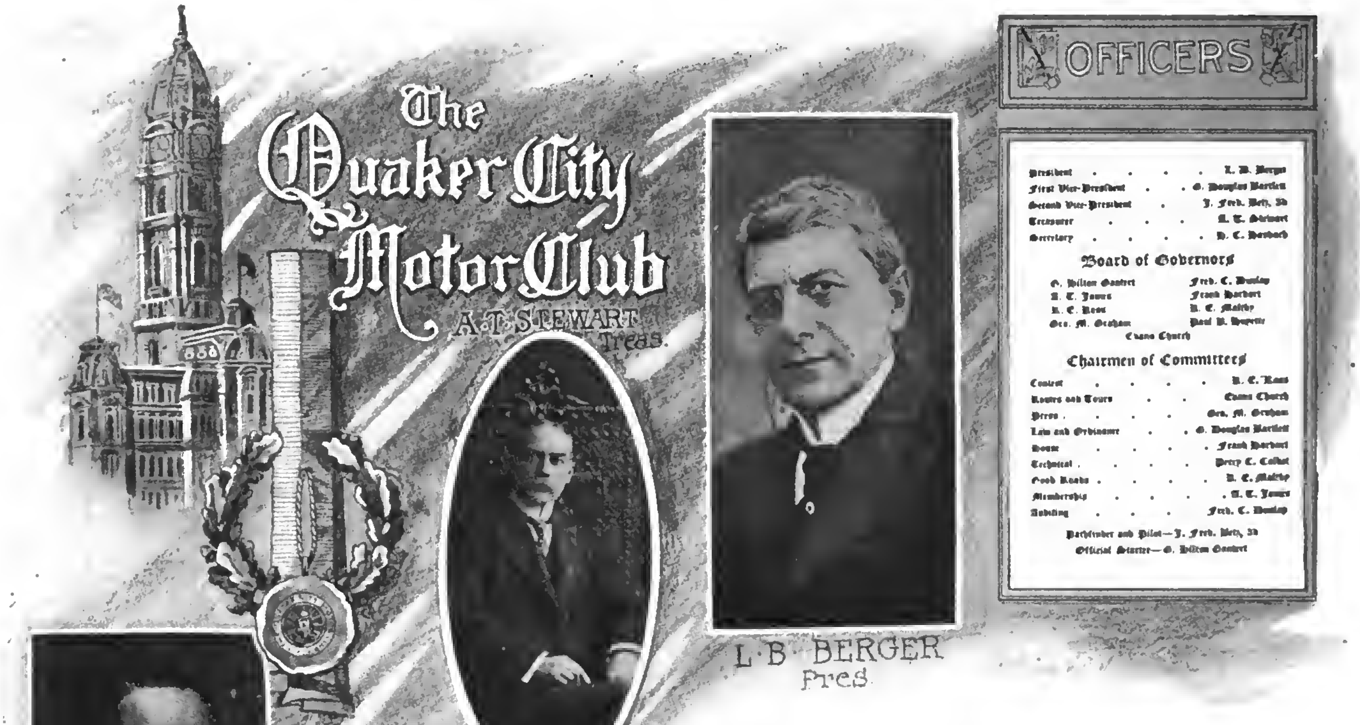
(B) Cadillac Thirty fitted with rapid-fire gun for army officers' use. The Northwestern Military Academy, Highland Park, Chicago, recently placed an order for a Cadillac Thirty fitted with a demi tonneau body, to which was added a Colt automatic rapid-fire gun. The armament was mounted directly upon the dash, so that it can be operated by the man alongside of the man at the wheel. With the gun equipment, the car weighs 2,500 pounds.

(C) Franklin six-cylinder car of 1910 model, which the owner, Mrs. Seaman, a Brooklyn woman, drove from the factory in Syracuse back to her home. The long trip was made without an untoward incident or a moment's trouble, which speaks volumes for the thoroughness of the factory testing of this make of car.

(D) A short time ago C. W. Matheson, president of the selling organization of the Matheson Motor Car Company, with offices in New York City, undertook to show to the newspaper and trade paper men of the metropolis the absolute silence of the new 1910 models of the Matheson, demonstrating at the same time the flexibility of the car by walking in front of it, throttled down, but with the high gear engaged.



A—HUDSON RUNABOUT, WHICH MADE TRIP FROM DETROIT TO TEXAS
B—CADILLAC THIRTY EQUIPPED WITH COLT AUTOMATIC RAPID FIRE GUN
C—MRS. SEAMAN DRIVING HER FRANKLIN FROM THE FACTORY TO BROOKLYN
D—DEMONSTRATION OF SILENCE AND FLEXIBILITY OF NEW MATHESON SIX



AN organization of motorists, actually popular with the general public and in high favor with the authorities of a great city, is rare enough to deserve special mention and such is the position and condition of the Quaker City Motor Club of Philadelphia. It is not the largest, wealthiest and most venerable body of men in Philadelphia, but the Quaker City seems to think that the club had an important part in controlling the recent street car strike, saving immense amounts of property and not a little of blood and violence and it is correspondingly honored. An active section of the membership formed a body known as the First Volunteer Motor Corps over two years ago and when the traction strike took place last February, the Emergency Patrol No. 1, formed of progressive members of the Quaker City Motor Club enlisted for the whole campaign.

The members were sworn in as special officers and the club donated the use of as many powerful cars as necessary and promptly assumed their duties. For forty days the motor corps was in service night and day and the concrete result was that whenever a riot call came in, there was a detail of police on the scene so quickly that disorder scarcely had a chance to get started before it was quelled.

The idea of the Motor Corps originated with Secretary H. C. Harbach and the working out of the details was performed by him. Charles J. Swain, former president of the club, was elected Commander of the Motor Corps and he was assisted actively by about a dozen of the leading members of the organization, under the direction of William Carleton Jackson. Behind this effective force stood the whole club membership. Special letters of thanks have been written to the corps by the municipal authorities, acknowledging the obligation of the city. The men who were notably active in this connection, include the following: Charles J. Swain, commander: William Carleton Jackson, Edwin H. Lewis, J. R. Overpeck, J. Fred Betz, third; C. Edgar Shreve, Richard Sellers, Louis G. Vogel and Edward B. Morgan, P. D. Folwell, G. Douglas Bartlett, A. T. James, A. E. Maltby, Frank Hardart, L. D. Berger. K. B. Harwood and A. T. Stewart were also in the thick of the fray for a considerable portion of the campaign.

The other principal claim to fame that is made for the club, is the fact that it fathers the Fairmount Park Race, one of the automobile classics. This race is run annually over an eight mile course in beautiful Fairmount Park and is 200 miles in length. The race is run the week after the Vanderbilt and it is estimated that last year 1,000,000 persons witnessed its decision. Besides magnificent plate trophies, the money awards to the placed cars. amount to thousands of dollars.

The race has one specially unique feature, in that the city receives all money realized from sale of seats and other concessions and divides it among several worthy charities. This fund is a material help to the institutions as it is liberal in size and constantly growing.

Aside from the Fairmount Park race, the club holds two race meets each year at the Point Breeze track and an annual Roadability Run. As described in a recent issue of THE AUTOMOBILE, the latter event will take place April 30, this year and will be to Atlantic City.

The club's quarters are in the Hotel Walton and while not large nor ornate, they are comfortably and tastefully fitted up The organization was started with a preliminary meeting Nov. 13, 1906, with George H. Smith, as president pro tem. in the chair. The first stated meeting was held a week later and the first regular meeting for organization was held at the Hotel

Majestic, March 7, 1907, when Charles J. Swain was chosen president. The first quarters of the club were in the Hotel Majestic from which removal was made to the Hotel Walton in March, 1909.

There are just 212 members on the club rolls, and each is an active, actual member with dues paid and interest alive.

Primarily the club is not a social organization, although about the usual percentage of its members take advantage of that feature of its life. It is dedicated to the sport of automobiling and its energy is directed toward popularizing the motor car by combatting prejudice and demonstrating its utility and enjoyable attributes. One of its chief aims is toward the general subject of good roads, acting as a factor in the State Federation of Automobile Clubs.

As an individual organization, the Quaker City Motor Club has done a vast work toward improving road conditions. Its road run from Philadelphia to Pittsburgh, over a course pronounced impossible by experts, was a mile-post in the history of motoring. It was costly for the club, but the spirit of the organization is the essence of good sport, so the club pocketed its loss and looked only on the remarkable accomplishment achieved by the race itself.

President L. D. Berger said that there was a tremendous field already open for useful work in the direction of improved highways. He pointed out that Pennsylvania is spending $4,000,000 a year in removing dirt from the gutters of country roads and placing it upon the surfaces of the driveways where the rains wash it back again and nullify the expenditure. He depreciated this sort of thing and said that the State organization, strongly aided by the Quaker City Motor Club was trying to provide for the expenditure of about $2,000,000 a year of the amount now wasted on the dirt roads, for the construction of permanent road improvements.

The men who form the club are prominent citizens of Philadelphia. They represent all lines of business and professional life and every phase of political faith, but they all unite in supporting the decalogue of the Quaker City Motor Club, which is as follows:

1. To assist all legislation for the furtherance of good roads.
2. To promulgate the idea that the automobile is the vehicle of the future and to strive for more liberal laws in regard to the same.
3. To encourage the automobilists in their realm of sport and to abolish impositions on the public highways.
4. To promote automobile contests in such a manner that the spirit of justice shall be embodied in all the rules and regulations.
5. To surround each event with the proper safeguard, so that an admiring public can witness the contests with full appreciation and perfect safety.
6. To endeavor to bring the sport of motoring to the highest level by the appointment of men of known experience and recognized ability as officers to carry on all contests.
7. To create new conditions in contests that will attract both the owner and the manufacturer.
8. To give trophies of intrinsic value, or rewards of real merit.
9. To promote social entertainment at stated periods during the year at which questions of the hour, referring to automobildom, can be discussed by capable men for the benefit of every member.
10. To make every man who owns an automobile feel that by belonging to the Quaker City Motor Club, he becomes part of an organization which is cohesive in principle and progressive in practice, ever ready to further the interests of the motor car, as well as to take care of the rights of the motorist.

In testing and contesting present laws, the club has tried to do a service to motordom generally. The contruction of the Pennsylvania statute as to the exact meaning of the term "chauffeur" was the work of the club. One of its members, Stanley Cooper, volunteered as a sacrifice and was arrested while driving a car belonging to a relative, he not having a chauffeur's license. He was fined in police court and on appeal the court of record held that a chauffeur is a paid driver and that Mr. Cooper had not broken the law. The matter is now pending on the State's appeal to the court of final resort.

The fundamental principle of the club is to subordinate individual and selfish aspirations and to unite to help the sport generally. In addition to this, much help will be given the industry as a whole, so serious as well as frivolous ends are served.

"CHAUFFEUR" IS A PAID DRIVER

Philadelphia, Apr. 11—"A chauffeur is one who drives a motor car for pay," decided Judge Staake of the Quarter Sessions bench, in a recent opinion delivered in the action of the Commonwealth vs. Cooper. Several months ago Assistant Attorney-General W. H. Hargest when asked for an opinion in the matter by the State Highway Department, ruled that a chauffeur meant anyone other than the owner, who operated an automobile.

This opinion was so fraught with significance to the automobile public generally, that the Quaker City Motor Club decided to contest such an interpretation and a test case was prepared. Stanley P. Cooper, a member of the club who did not have a license, borrowed his sister's car and drove up Broad Street and around the city hall until he was arrested by a policeman who had been informed that Cooper did not have a license. He was fined $10 and appealed to Quarter Sessions where the appeal was sustained and the legal status of the chauffeur definitely outlined.

In his opinion Judge Staake declares that the laws of every State in which automobile laws have been passed, define the term "chauffeur" to include the idea of compensation for the operation of a vehicle. He said that if it had been the intention of the Legislature to require all operators of motor cars to be licensed under the present law, it would have made specific provision for such a condition. Under the ruling of Mr. Hargest it would have been necessary for each member of the family of a car owner, who wished to drive and who might be thoroughly competent to do so, to take out a license.

MARYLAND LAW SATISFIES MOTORISTS

Baltimore, Md., Apr. 11—Maryland's new automobile law will be in operation May 1, when the Commissioner of Motor Vehicles, created by the law, will begin his duties. This law, known as the Swann Motor Vehicle law, was passed by the Maryland Legislature and has been signed by Governor Crothers. There have been no kicks registered against it as it now stands, for the members of the Automobile Club of Maryland and members of the State Automobile Commission got together before the bill was introduced in the General Assembly and reached a compromise on the license fee section and other details that were not altogether to the liking of the motorists.

In consequence of this, some of the officials of the club were among those at Annapolis to speak in favor of the adoption of the law. That the law was adopted, too, was due to the efforts of Col. Sherlock Swann, author, and State Senator Linthicum, both of whom are members of the commission, as well as Governor Crothers, who backed the bill from the time it was framed.

FLORAL PARADE TO BE FEATURE

Chicago, Apr. 11—The Chicago Automobile Trade Association has decided to hold its floral parade May 7 in the afternoon. It is planned to have at least 500 cars in the turnout, and the awards will be made by a committee of prominent society women. There will be four divisions in the parade, three prizes being awarded in each. Much interest has already been aroused, so that success is assured.

Will Windshields Break at High Speed?

Editor THE AUTOMOBILE:

[2,224]—I have lately become a subscriber to "The Automobile" and am quite interested in the "Letters Answered and Discussed" section. I wish you would answer a question for me.

I frequently hit up a pace of 45 to 50 miles an hour when out on long trips in my machine, with the windshield up. Is this a safe thing to do? I have been told that the glass is liable to break from the air pressure against it. The shield is a standard make, flat front type, with a brass-bound seam across the center.

Was the Pope-Hartford machine that made such good time in the Portola race a stock chassis or a special? S. L. P.

The attention of readers is again directed to the note which appeared in these columns last week, requesting name and address with each letter. This letter came without name or address except the initials, but as it arrived before the warning we are using it, also for the sake of the interesting question which it brings up.

The pressure of the wind at a speed of 50 miles an hour, according to various authorities, may be taken at about 10 pounds per square foot. Fairbairn gives the following formula for the strength of a glass bar: $w = 3{,}140 \dfrac{bd^2}{l}$, which would give a modulus of rupture of 4,710 pounds. The formula for the breaking load of a beam supported at the ends and loaded uniformly is $W = \dfrac{4\,Rbd^2}{3l}$. Assuming a plate of glass one foot high, three feet wide and 3/8 inch thick, supported at the ends only, and substituting the known quantities, $W = \dfrac{4 \cdot 4{,}710 \cdot 12 \cdot 9}{3 \cdot 36 \cdot 64} = 294$ pounds. Compared to this, the 30 pounds pressure on the three square feet of surface presented to the wind is quite insignificant, the factor of safety being about ten.

Although most people do not appreciate the fact, glass is a comparatively strong substance. Its weakness is against sudden shocks rather than against steady loads. The 100 pounds per square foot pressure necessary to break an ordinary wind shield would only be attained at a speed of 160 miles an hour, which would be "going some," even for Barney Oldfield.

The Pope-Hartford that won the Portola race was a stock chassis.

License Fees and Car Ownership

Editor THE AUTOMOBILE:

[2,225]—Kindly answer the following questions in the columns of "Letters Interesting, Answered and Discussed"? Do I have to get a license or pay a fee to the city or state, to run a hacking car and own it? CONSTANT READER.

New York City.

Yes, it is a necessity to have a license for the car whether it be run as a hacking car or for pleasure. A New York State license is bought but once, and is perpetuated by request, so that the expense is very small. There would be no additional fee to pay to the city for a pleasure car, but a hacking license would be necessary, for which a small license fee is charged. That is, one fee for the car, whatever its use, and another fee to the city for a hacking car, would have to be paid.

Some Questions of Fact and Theory

Editor THE AUTOMOBILE:

[2,226]—Will you please answer the following questions through "Letters"?

1—Was the Marmon "50" ever fully described in "The Automobile" or any other journal? If so, please refer me to same. The Nordyke & Marmon Company does not make this car any more, but I wish to know something about it.

2—What kind of a clutch was used in this car? I am informed it was an excellent one and would like to know its mechanism.

3—Kindly give me some information on the subject of the differential; this is a part of the car I do not fully understand.

4—Does a car derive more power by adjusting the carbureter so that all the gasoline possible is given with a proper proportion of air, or is it better to give less gas and less air? What I mean to say is, are the very best results obtained by mixing the most gas and air possible, or are just as good results obtained by cutting down the amount mxed? GEO. W. WILSON, JR.

St. Louis.

Nordyke & Marmon never made a car rated at 50 horsepower. Their highest-powered car, to which you no doubt refer, was the 1908 model H, rated at 40-45 horsepower. As the cylinders of this car were 5 by 5 inches, 50 horsepower would not be an excessive rating, as things go. This car was described at some length in THE AUTOMOBILE, issue of January 16, 1908.

The clutch of this car was a multiple-disc, consisting of a comparatively small number of bronze plates studded on both sides with cork inserts, and alternating with steel plates. The Marmon Company now uses a leather-faced cone clutch.

When a car goes around a corner the outer wheels travel further than the inner ones, and so must turn faster. The differential allows them to do this, at the same time transmitting the driving power to them. One of the standard forms of differential has bevel gears on the inner ends of each of the live shafts, facing each other; three or four bevel pinions between these gears, their shafts radiating from the center of the live shafts; and a cage surrounding the gears, in which the pinions have their bearing, and on which is bolted the main bevel gear driven by the motor. The arrangement is such that if the cage is held stationary and one of the live shafts rotated, the other live shaft will rotate in the opposite direction, the differential acting as a reversing gear.

In action making a turn, the main bevel gears may be turning at a speed which would give each of the live shafts a speed of 100 r.p.m.; then if the outer wheel turns at 125 r.p.m., giving that side of the mechanism a positive velocity of 25 r.p.m. above normal, the differential, in its capacity of reverse gear, will transmit to the other live shaft a relative negative velocity of 25 r.p.m, reducing the speed of the inner side to 75 r.p.m.

The more gas, the more power, up to the maximum capacity of the cylinders; if it were possible to force the gas into the cylinders under pressure, still more power could be obtained. Cutting down the amount of gas, as you suggest, is simply throttling the motor, and will inevitably result in less power.

Date of Selden Patent

Editor THE AUTOMOBILE:

[2,227]—Will you please answer the following questions and greatly oblige an interested reader of "The Automobile?" On what date does the Selden patent expire? Is there any possibility of the owners of this patent gaining an extension after or beyond that date? Can any one build automobiles after that date without paying any royalty? F. R. ZEIGLER.

Oregon, Ill.

The Selden patent application was filed on May 8, 1879, and the patent was granted on November 5, 1895. Since the term of a patent is 17 years, the patent will expire on November 5, 1912. The sole object of a patent is to protect the inventor from the promiscuous use of his ideas during that term of years, and beyond that the Government does not go. That is, after the expiration of the 17-year term, the idea becomes public property and any one may manufacture, buy or sell machines embodying the formerly patented idea freely and without hindrance. On page 728, a discussion of this matter will be found.

Garage and Repair Shop Arrangement

Editor THE AUTOMOBILE:

[2,228]—I am a reader of your paper and am about to put up a garage to hold from twenty-five to thirty cars combined with a repair department. The building will be 85 ft. front by 66 ft. deep, and with a basement under part of it. Will you kindly let me know the best way of arranging the construction so that it will be efficient and convenient? Try and give me whatever suggestions you can to make the building suitable for the motor business. If you have had, in the past, any articles in your paper which bear on the subject, I would appreciate it if you would mail the issues to me and I will remit on receipt of your bill. J. SERHEGER.
South Bend, Ind.

Generally speaking, each car should have a floor space of at least 9 ft. width by 15 ft. length, or 135 sq. ft. This is not an invariable rule, and many garages find themselves able to handle cars right along in less space, but it is an average size which good practice would call for. This size of floor space would call for about 4,100 sq. ft. for 30 cars, while, in addition, an aisle down the center not less than 10 or 11 ft. wide would be a necessity. This in the depth of building mentioned would add about 700 sq. ft., or make the total 4,800. Since the building as spoken of would have over 5,600 sq. ft., the size is on the safe side. As to arrangements, that varies with individual preference and the location and character of the cars handled, the patrons of the place, and many other things. One very good plan is to have the ground floor given up entirely to live storage, with a specified, numbered place for each regular car. Then, utilize the top floor, or at least one of the upper floors, for dead storage. This will take little space, probably not more than half of one floor in the above case, and the balance of the floor can be given over to painting, varnishing and upholstering shops. Another floor should be given up to repair and machine shops, while the basement can be utilized for storage of materials, parts for the cars handled, and old or second-hand cars taken in trade. If an agency is to be taken as part of the program, the best part of the ground floor should be selected for this purpose.

In any case, the office should be alongside of the door, through which the cars must enter and leave. In the basement would also be placed the power plant, the air compressor, and similar tools. Provision should also be made for lockers, both for the men employed in the building and for the patrons. They should be located in a clean, light place, and made preferably of steel.

In starting a garage, much thought should be given to a simple yet comprehensive system of keeping the books. The materials of the garage, its floors, and its equipment, will all depend upon the tendency of the owner and builder, as well as to the class of people to whom the garage will be a home for their cars. In a series of articles about to be started in the paper, prominent New York garages will be described in detail, with illustrations, and where possible, floor plans. This series of articles will be of much use to you, and will start in this issue, the first one being found on page 739.

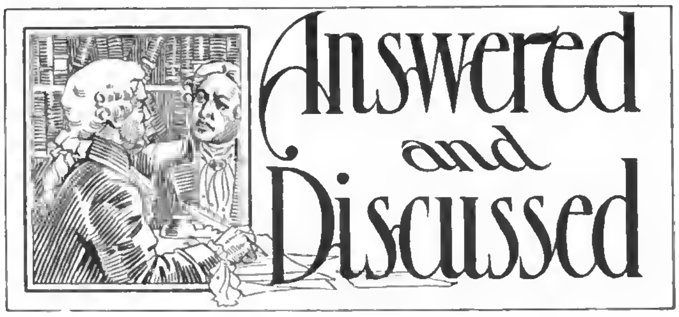
Polishes for Metal Work and Bodies

Editor THE AUTOMOBILE:

[2,229]—Will you please advise us as to the best metal polish and body polish on the market? CLIO MOTOR COMPANY.
Clio, S. C.

We cannot recommend preparations quite so definitely as you seem to desire, for obvious reasons. Besides, the best polish is largely a matter of personal opinion, and equally well-informed persons might favor different kinds. There are any number of special preparations on the market, many of them advertised in the advertising pages of this magazine, and we think it quite safe to say that any one of them, if used in accordance with the directions, will prove quite satisfactory.

For metal work a cheap and satisfactory polish may be made from whiting cut with gasoline. Of course, this must be prepared fresh whenever used, as the gasoline quickly evaporates; but as there is always plenty of gasoline around a garage, this will not be found a great inconvenience.



French Automobile Publications

Editor THE AUTOMOBILE:

[2,230]—Can you please give me the name and address of some good French automobile publication, of about the same high character as "The Automobile"? I would appreciate this information very much, or any information regarding French papers, as I subscribe to "The Automobile" and am very much pleased with the same. A. W. B.
Milwaukee.

There are about a half-dozen papers in the list of best published French papers. *Omnia* is published by L. Baudry de Saunier at 20 Rue Duret, Paris, and costs 25 francs per year. It is of a technical or semi-technical character, and contains on an average 20 pages per week. *La Vie Automobile* is a weekly, published by Charles Faroux at 47-49 Quai des Grands Augustins, Paris, at 25 francs. It is of a less technical character than *Omnia*, but a monthly supplement, *La Technique Automobile et Aerienne*, is devoted entirely to that side. The former amounts to about 16 pages per issue, while the latter is of the same size. The price of the technical sheet is 12 francs per year.

L'Automobile is a weekly in which more attention is given to clubs, sporting news, novelties, racing and the like than to technical matter. This is published at 19 Rue des Saints-Pères, contains 16 pages per issue, and is of slightly larger size than the usual. *La Pratique Automobile* is a weekly published by Mortimer Mégret at 12 Avenue de la Grande-Armee, Paris, at 13 fr. 50. Its 20 pages, of small size, are devoted entirely to sporting events of the automobile and aeronautical world.

Then, there is *La France Automobile et Aerienne*, the latter part of the name being a recent addition. It is a weekly of the usual size, 16 pages per issue, and 20 fr. per year. The subject matter is only slightly technical in character, and of late has assumed, coincident with the change in name, a decidedly aeronautical tone.

Why Do Not All Use Friction Drive?

Editor THE AUTOMOBILE:

[2,231]—Please answer in the columns of "The Automobile" the following questions:

1—Why do not all automobile manufacturers use the friction transmission instead of selective or planetary, and do away with the disc or cone clutch, etc.?

2—Is not the friction transmission more desirable on account of obtaining any speed from zero to limit on high gear?

3—Does not a car with friction transmission get more power delivered to the wheels than a car with any other kind of transmission of equal horsepower?

4—Is it not cheaper as to wear and cost of replacing to have a friction than a gear transmission? R. F. HENRY, JR.
Palm, Ala.

Probably the reason why all makers do not use the friction drive is that they do not believe it is the best for their purposes. We doubt if the average user of this gear uses more than three or four of the speeds available; he gets that many favorite positions and does not bother about the intermediate ones.

Friction transmissions, of the simple disc type, are never on the high gear, that is, in the sense that a car with direct drive on the high can be. The friction drive gets more power to the wheels than a sliding gear on its low speeds, but not so much as a sliding gear on high speeds. The friction discs must be replaced every few thousand miles, although the expense is small.

The Duration and Term of the Selden Patent

By XENOPHON P. HUDDY, LL. B.

THE SELDEN PATENT, which was declared valid by the Circuit Court of the United States for the Southern District of New York on September 19, 1909, was granted by the Patent Office in 1895 on an application filed in 1879, more than 16 years before the grant was made. The patent therefore has a remaining period of duration and term of two more years, provided that an extension is not obtained by a special act.

To those who are waiting for the expiration of the remainder of the term of this patent, let it be said that too much dependence should not be placed upon the patent rights being extinguished in 1912 and then becoming general public property. The Selden patent is now valid and alive. It has not yet expired, and until its life ceases forever, hopes should not be indulged in and plans should not be made too definite. Even though the seventeen years of the Selden patent cannot be extended under any general law, its life may be prolonged by a special act of Congress, the same as the Government has done in many other cases.

POWER OF CONGRESS TO EXTEND TERM

Congress possesses the power by means of a private act to grant an extension of a patent, even after the patent has expired and the invention has been introduced to public use. The patent thus extended is to be regarded as a patent for the entire time from the first grant to the end of the extended period. A person making articles under the patent in the interim between the expiration and extension has no right to use them after the extension is allowed.

Prior to the act of March 2, 1861, a patent ran for 14 years, with the privilege of extension for seven years longer, but by that act the term was limited to 17 years without a privilege of extension given under the statute. There is now no general act permitting a patent to be extended, so the only right which a patentee possesses is to apply to Congress for a special act. Whether Congress will grant an extension of time will depend upon the facts and circumstances of each case.

FACTS WARRANTING SPECIAL EXTENSIONS

At the expiration of the present term of the Selden patent the owners thereof have the right to apply to Congress for an extension of its life. In determining whether the application for the extension will be granted by Congress, the primary question to be answered is whether in justice the holders of the patent should receive an extension.

It may be claimed that the rights of the Selden patent are being grossly and openly violated, and that the holders of the patent have lost, and are losing, large sums of money which they are entitled to under the decision of the United States Circuit Court upholding the grant. The natural question to be asked, then, is, if the owners of the Selden patent have received all that is justly due to them under the patent during its term? These facts, taken into consideration with the fact that the patent was not granted until 16 years after its application, and the further fact that the automobile industry is one of modern development, would be most influential in obtaining from Congress the passage of a special act extending the term to expire several years hence.

Congress possesses the power to do this, and has often exercised this power. The following cases are referred to:

In the case of Jordan vs. Dobson, Fed. Cas. No. 7,519, the United States Circuit Court held that Congress has the power to authorize by special act the extention of a patent, notwithstanding the fact that the original patent had previously expired, and the invention has been introduced to public use. The court also held that a special act of Congress authorizing the extension of a particular patent should not be read and construed in connection with the general acts on the subject. In this case it was contended that Congress had no power to extend a patent by special act, but the court said:

"The eighth section of the first article of that instrument [the Constitution of the United States) ordains that Congress shall have power to promote the progress of science and useful arts, by securing for limited times, to authors and inventors, the exclusive right to their respective writings and discoveries. This is a large power. It is not said when those limited times shall commence, how long they shall continue, or when they shall end. All that is left to the discretion of Congress."

In the case of Union Manufacturing Company vs. Lounsbury, Fed. Cas. 14,368, a patent was also extended by a special act of Congress. The court held, however, that where certain representations were made to Congress, upon the faith of which a patent was extended by a special act of Congress, the patentee will be held to his representations.

In July, 1862, Congress by a private act extended an expiring patent issued to Etienne Bernot, the inventor of a machine for cutting files. See New American File Co. vs. Nicholson File Co., 8 Fed. Rep., 816.

The patent for Woodworth's Planing Machine was extended from 1842 to 1843 by the Board of Commissioners. In 1845 Congress by a special act extending the time still further, from 1849 to 1856. See Bloomer vs. McQuewan, 14 How. (U. S.), 539, wherein the Supreme Court of the United States held as follows:

First—That a special act of Congress in favor of a patentee, extending the time beyond that originally limited, must be considered ingrafted on the general patent law.

Second—That under the general law in force when the special act of Congress was passed, a party who had purchased the right to use a planing machine during the period to which the patent was first limited was entitled to continue to use it during the extension authorized by that law. (This would apply to users of licensed cars.)

The extension of a patent may be granted to an assignee or to an administrator. Washburn vs. Gould, Fed. Cas. No. 17,214, wherein it is also held, in support of the recent Selden patent decision, that whoever finally perfects a machine and renders it capable of useful operation is entitled to a patent, although others may have had the idea and made experiments toward putting it into practice, and although all of the component parts may have been known under another combination or for a different purpose.

Wrights Define Their Patent Position

During his visit in New York last week, on returning from an inspection of the new aviation farm at Montgomery, Ala., Wilbur Wright issued a statement defining the position of the Wright Company toward aviators infringing the Wright patents.

"The report that we will permit any biplane or monoplane, regardless of who makes it or where, to compete in any aviation meet in this country is untrue," said Mr. Wright. "Unless its owner and navigator takes out a Wright license and agrees not to compete in unlicensed meets, we shall prevent their flying.

"We obtained the first aeroplane patents in 1906, and we have seventeen years, thirteen more, in which to enjoy our monopoly, provided we make our invention salable and protect it by law. That is the explanation of litigation instituted during the year."

Mr. Wright was asked regarding a recent report that the Government might purchase his patent rights and throw the field open. "Such a thing is possible, but hardly probable," he replied, "though nothing would please my brother and myself more. There was talk of something of that sort several years ago, but it fell through. We were approached by a committee of the Aero Club of America, which wanted to buy our patents. The offer looked big to us then and we might have accepted it, but the Aero Club committee allowed the matter to drag along until we put the question squarely up to them. We never received a reply, so we went ahead and developed our own invention.

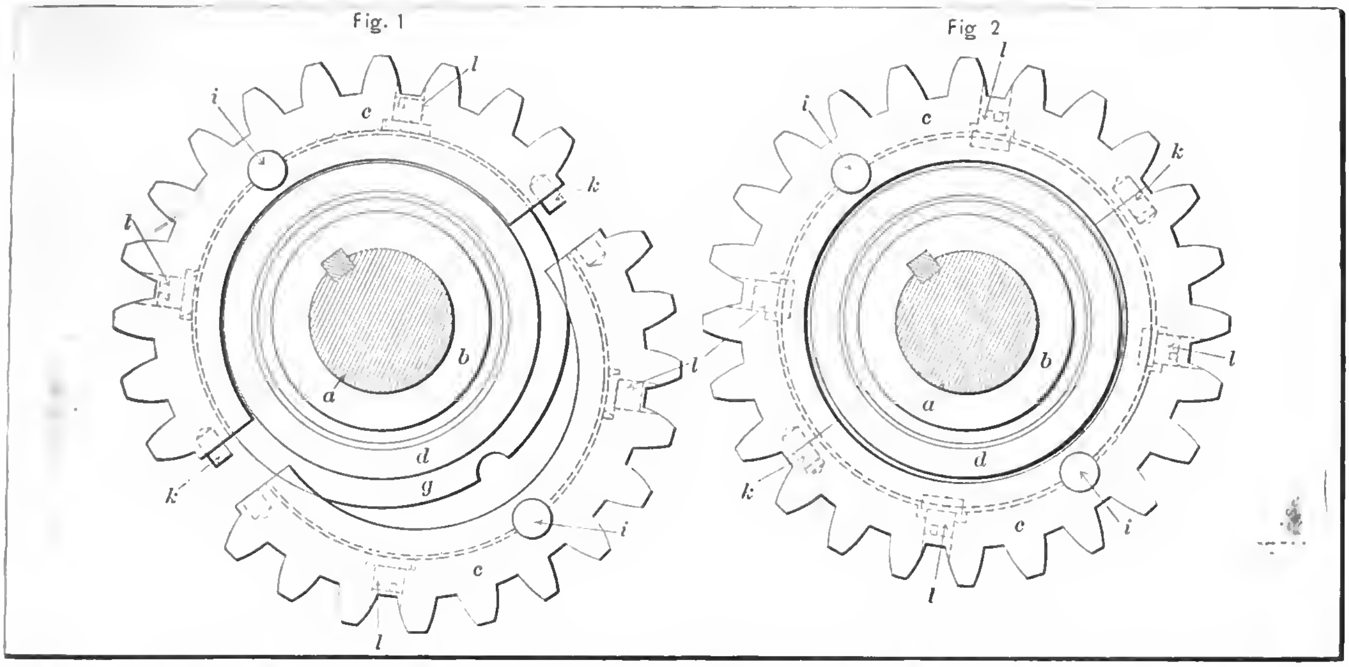


Fig. 1—Showing two sections of a gear made with the Sparr locking device, one half-gear being partly removed. Fig. 2—View of gear with Sparr device assembled and locked ready for use. i, i are the locking screws, l, l are the locking pins, and k, k the dowel pins

New Gear-Locking Device Appears Meritorious

WITH the modern tendency toward simplicity and small number of parts, many inventors have been induced to work on devices which either lessen the number of parts or improve the simplicity of the automobile as a whole. Any device which may be said to lessen the work of assembling or dissembling would come in the class of those simplifying the whole machine.

This is the exact definition of the locking mechanism which has just been invented by a Brooklyn man, Benjamin F. Sparr, and which is illustrated and described herewith. As the patent specifications state, "the object of this invention is to provide a separable or split gear, which may be put on or taken off a shaft without having to be slid along the shaft to and from the end." This is the case with all ordinary gearing, which is made solid with either a round or square hole through the center. To assemble or dissemble, the gear must be slid along the round or square shaft either from the end to its place in case of assembling, or from its place to the end, in the instance of dissembling.

Sparr does away with this by making the gear in two halves, which halves are locked to the shaft by means of a dovetail. In this dovetailed groove, a double locking ring, fundamentally narrower than the groove, locks the ring and shaft together by expanding sideways through the medium of a left and right-hand thread, each actuating one half of the locking ring. This movement of the locking ring is brought about by holding either the shaft or gear and rotating the other. When properly locked in place, the reverse or unlocking process is prevented by one or more taper-ended set screws, of the headless type, which are screwed in between the two halves of the locking ring, the inner faces of this being tapered to facilitate this action.

As the figures show, the two halves of the gear are made with dowel pins, for exact replacement, while a pin is driven through one half of one gear, so as to present a half-round projection into the groove, upon which an indentation on the locking rings fits.

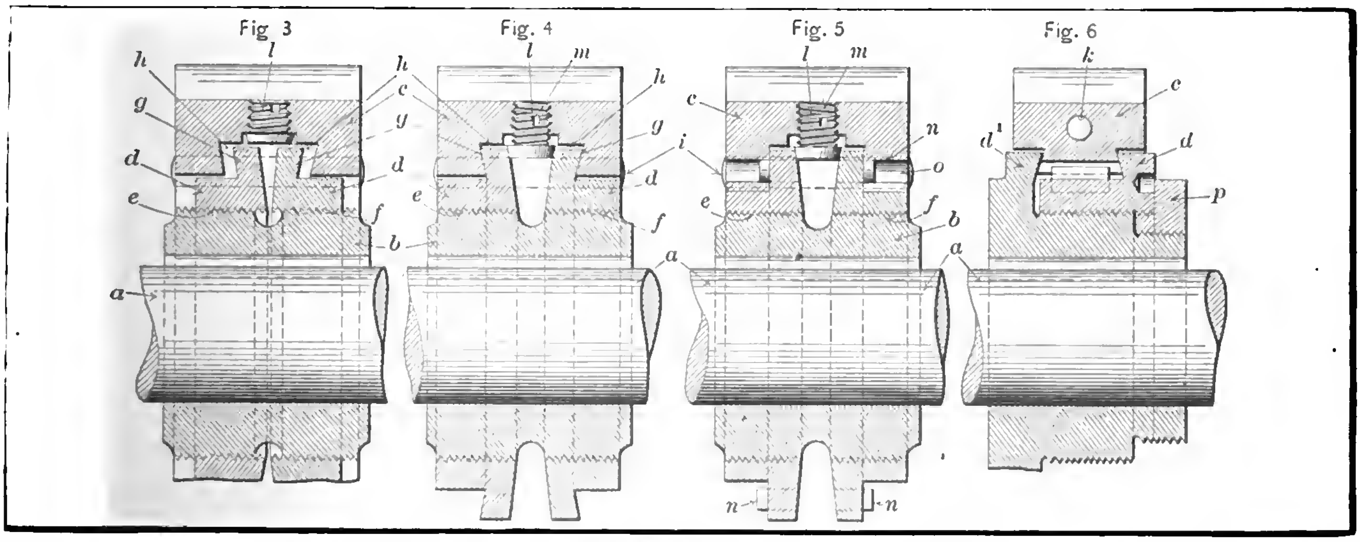

Fig. 3—Section through gear and shaft showing locking ring before expanding. Fig. 4—Same section showing the ring expanded so as to clutch the gear to the shaft, the taper ended set screw to prevent backing off being down into position. Fig. 5 and Fig. 6—Show two alternate methods of constructing the same device, one with an external taper instead of internal, the other with pins in a groove

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

The First Annual Banquet of the Association of Licensed Automobile Manufacturers, which was held at the Hotel Astor, April 7, brought together the executive representatives of 83 makers of automobiles, and the leaders of acumen in the industry who were there for the express purpose of enjoying an evening in each other's company. This is probably the first time that the captains of the automobile industry were enabled to assemble under conditions which would bring out expressions of a character which might be regarded as a true estimate of just what the automobile does mean to the industry, and to the public at large.

Something of the vastness of the automobile industry was reflected in the statistics utilized by Governor Fred M. Warner of Michigan, in his leading speech, and the best estimate, perhaps, to put upon the figures offered, is that they reached into such large numbers that they cease to be comprehensible. These figures were confined to the State of Michigan, and if, in a few short years, an industry reaches such proportions that statistics cease to convey information when they are confined to a single state, it does seem as if a project such as this has epoch-making principles.

It was pointed out, in the course of the evening, that the automobile, in addition to offering a means of livelihood to men counted in hundreds of thousands, is slowly but surely mending the hard spots in our form of civilization. It gives a means by which the farmers may transport their products to the market, without having to rely upon the less direct and more costly methods.

The very opposition offered to the automobile as the reliable agent of men of affairs, which opposition is expressed by immaturely contrived and vicious laws, is one of its most pronounced manifestations for good; it exposes the pigmy mind, and tells the world at large of the legislator who formulates at the dictates of his own pocketbook, and blinds him to the fact that the automobile, because of its merit, is the chariot wheel to which he is tied, that will roll him into the sea of oblivion.

As Colonel Charles Clifton very aptly and appropriately reflected, the co-operation which has been thus far extended by the builders of automobiles in America, has merely results in the crystallization of effort, and the elimination of useless and ill-advised opposition. The inertia of thoughtlessness and prejudice has had its say, it has done its best to bar the onward march of the automobile, and the time has arrived when nothing remains but to continue along co-operated lines, looking at things broadly, and remembering that inherent worth must govern the combined effort of the co-operators, and this will only be possible if worthy effort obtains at the behest of the individuals in their several walks.

It was stated, among other things, that the cost of all the automobiles which are made in a single year is a lower figure than the cost of repaving the streets of a single large city in that time, and it was also pointed out that repaving is brought about in consequence of deterioration, which may be directly traced to the presence of horses as used for transportation purposes. This deterioration is direct, in so far as shod feet destroy asphalt surfaces, and indirect by the process which will be here described as the chemical reactions involved, due to the presence of litter on unclean streets. It was said that in the long run, when automobiles only are used on city streets, the cleaning problem will be reduced to the efficacy involved in a machine process, and the cost will be reduced to the level of an infinitesimal increment relatively, whereas the advantages will be so enormous that they will be difficult, if not impossible, to count.

One maker of automobiles claims the proud distinction of having started an addition to its plant every week in every year of its existence so far. Whether or not this company has done more or less adding to its plant, as compared with divers other companies, is not the question of the moment. Additions are being made at a terrific rate in all the automobile centers in this country, and thanks to the foresight of the directors of the respective plants, these additions are of a permanent character. The buildings are, for the most part, of reinforced concrete construction, taking pattern after the most scientific processes of the day, incorporating into the plan the idea that no artificial means can be regarded as the rival of daylight, and it is to be had with a saving which is equal to the cost of the walls which are too frequently placed to exclude it. The saw-tooth idea has its substantial adherents, but some of the conditions of manufacturing demand a measure of concentration, and this requirement leads to the construction of buildings at least two or three stories high, which is not found to be sufficient reason for the exclusion of daylight—in modern industrial plants the sun shines for all, even the workmen at the bench.

Detroit Makers Push Building Rapidly

EXPANSION is the order of the day among Detroit automobile manufacturers, who find themselves in many instances unable to meet present demands. As a result, building activities are reaching hitherto unheard-of proportions. Chief among the concerns which have outgrown their present quarters is the Warren Motor Car Company, organized something less than a year ago. Work is already under way on the first of a group of factory buildings, the initial structure to be two stories and 600 by 60 feet. Two others will follow, each approximately 400 by 60 feet, and it is expected to have the last of these completed before the first of next year.

The Grabowsky Power Wagon Company has also begun the erection of a new plant, the principal buildings in which will be 300 by 62 feet and 200 by 40 feet, the latter to be used as a body building plant. Reinforced concrete will be used throughout, and the structures will be models.

The Long Manufacturing Company, of Chicago, makers of automobile radiators, auto tubings and other parts, will erect an immense plant in Detroit. The main building will be two stories, 325 feet long, and so constructed that four wings can be added to the rear.

The Detroit Dearborn Motor Car Company, which recently increased its capital stock from $50,000 to $100,000, is building an addition to its plant that will double its capacity.

Plans for the new Lozier plant have also been completed, and are now in the hands of builders for the purpose of receiving contracts. Work will be begun as soon as possible, and it is hoped to have a portion of the plant completed by midsummer. Organization of the company has been perfected, with the following officers: President, H. A. Lozier; vice-presidents, Gilbert W. Lee and Fred C. Chandler; secretary, Cyrus E. Lothrop; treasurer, Charles H. Hodges.

Work on the Michigan No. 1, the first of the big balloons being constructed for the Aero Club of Michigan, is progressing favorably, and its delivery is looked for about May 15. It will be a 40,000-foot sack, capable of carrying a pilot and three passengers. Meanwhile, members of the club are planning for preliminary flights some time this month, under A. Leo Stevens

Proposed Reform for Stock Car Races

IN ORDER to insure the participation of bona fide stock cars only, in competitions designed for that class, Windsor T. White, president of the White Company, proposes the adoption of a rule similar to the selling and claiming clauses which are operative in the horse-racing world, with reference to selling races. These clauses provide that the winner shall be sold at auction to the highest bidder over the entered price and that the owner of any contestant in the race may lay claim to any other entry that finishes behind the winner by paying the entered price plus the amount of the first money awarded.

Mr. White says by the adoption of a rule allowing the owner of any car in a race to claim any other car by paying the list price of the claimed entry, that the suspicion which has existed for a long time that "stock cars" intended for racing are specially constructed and prepared would be nullified.

He declares that from the viewpoint of the public there is no good reason apparent why a "stock car" which competes one week in New York, should be rushed by express to New Orleans or Minneapolis to take part in races, if there was not some tangible basis for the public's suspicion.

He believes that the enactment of such a rule as he suggests would have an immediate and beneficial effect upon automobile racing and that its enforcement would mean the discouragement of building specially constructed cars for stock car contests

Coming Events in the Automobiling World

Apr. 9-16........Elmira, N. Y., State Armory, Automobile Show, Elmira Chamber of Commerce.
Apr. 11-16........Harrisburg, Pa., Kelker Bldg., Automobile and Sportsman's Show, Harrisburg Automobile Dealers' Association. B. R. Johnson, Manager.
Apr. 11-16........Erie, Pa., Meyer Block, Automobile and Motorcycle Show.
Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.
June 20-July 6....Detroit, Mich., Industrial Exposition, Detroit Board of Commerce.
Jan. 7-14, 1911....New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.
Jan. 17-24, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Feb. 13-25, 1911...Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

Apr. 13-17........Los Angeles, Cal., Inaugural Meet, Motordrome.
Apr. 30-May 2....Philadelphia Roadability Run to Atlantic City, Quaker City Motor Club.
May 2............Flag to Flag Endurance Contest, Denver, Col., to City of Mexico.
May 5-7..........Atlanta, Ga., Track Races. Atlanta Automobile Association.
May 9-11.........Harrisburg, Pa., Fourth Annual Reliability Contest to Atlantic City and Return.
May 21-22........Bay Ridge, L. I., Club's Endurance Contest Around Long Island, Crescent Athletic Club and Long Island Automobile Club.
May 30...........Bridgeport, Conn., Hill-Climb up Sport Hill; Automobile Club of Bridgeport.
June 11..........Wilkesbarre, Pa., Annual Hill-Climb up Giants' Despair, Wilkesbarre Automobile Club.
June.............Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, through the Southwest.
June.............Worcester, Mass., Hill-Climb up Dead Horse Hill, Worcester Automobile Club.

Foreign Shows and Races

Apr. 2-24.........Turin, Italy, Automobile Show.
Apr. 27-28........Brooklands, England, Two-Day Meeting.
May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.
May 25...........“The American Cup,” Argentina, Sociedad Sportiva Argentina, near Buenos Ayres.
May 28-June 9....St. Petersburg, Russia, Automobile Exhibition.
May 29...........Copa Catalunya, Voiturette Race of the Royal Automobile Club of Spain, near Barcelona.
June 2-8.........Prince Henry (German) Touring Competition.
June 13-18.........Scotland, Scottish Reliability Trials.
June 20..........French Voiturette Race.
June 21..........French Stock-Car Race.
June 22-July 5....Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.
June 27..........Speed Trials at Kiev, Russia.
July 12-18........Ostend, Belgium, Automobile Week.
July 20-25........Boulogne, France, Automobile Week.
Aug. 1-15.........Ardennes, France, Meeting.
Aug. 15-Sept. 15..French Industrial Vehicle Trials.
Aug. 21...........Salon, France, One and Five Kilometer Trials.
Aug. 28...........Mont Ventoux, France, Hill-Climb.

Grand Prize Race Conditions Now Given Out

THE international race of the Motor Cups Holding Company for the Grand Prize of the Automobile Club of America has been announced for October 15, on the Long Island Motor Parkway. The gold challenge cup, valued at $5,000, is the chief award to the winner. All makes of cars are eligible, but no more than three cars of any one make may be entered. The length of the race is the same as the Vanderbilt, 278.08 miles, 22 times around a course of 12.64 miles.

Entrance fees are $1,000 a car, $1,500 for two cars of the same make and $1,750 for three cars of the same make. Regular entries close August 1, but until September 1 special entries may be made at an advance of $250 a car.

On account of the latitude allowed entrants, it is expected that there will be a big field, and under the rules some sort of elimination trials will be held if the number of competitors appears to be unwieldy.

AVIATOR LE BLON IN FATAL ACCIDENT

SAN SEBASTIAN, SPAIN, Apr. 2—The name of Hubert Le Blon has been added to the roll of aeronautic fatalities. He was killed here to-day while making an exhibition flight near the royal palace of Miramar. Owing to the stormy weather he had not been expected to ascend, and only a few persons had assembled to see the start. He was flying at a height of 140 feet when his motor broke down. He attempted to glide to the ground, but the machine was overturned by a cross current and dashed against a rocky cliff. Death was instantaneous.

Le Blon took part in the Vanderbilt race of 1906, and had many friends in America. He took up aviation last Summer as a pupil of Blériot, and distinguished himself at the Heliopolis meet in February by setting a new 5-kilo. record of 4 mins. 2 secs.

QUICK STARTS AT MEMPHIS AERO MEET

MEMPHIS, TENN., Apr. 9—Glenn H. Curtiss lowered his world's record for quick time in starting last Thursday, making the start in 5 4-5 seconds, as against his mark of 6 2-5 seconds, made at Los Angeles. At the same test he failed to break his short-distance starting record of 98 feet. After this flight the aviator took up his wife as passenger for her first ride.

Charles Willard, one of Curtiss's pupils, had engine trouble, and was forced to descend before completing one round. Friday he was still unable to get his machine in good order. J. C. Mars, another of Curtiss's pupils, made several good flights on both days. Friday Curtiss equalled his quick-start record.

AERO CLUB INSURGENTS RENEW FIGHT

The insurgent faction in the Aero Club of America, which brought injunction proceedings against President Cortlandt F. Bishop to prevent voting by proxy and thereby defeat his reelection, renewed their activity last week by the publication of an open letter demanding his resignation. The letter asserts that owing to President Bishop's poor management America is in danger of losing the international aviation meet, and demands some radical action to restore public confidence.

NEW AEROPLANE PASSENGER RECORD

CHALONS, FRANCE, Apr. 8—Daniel Kinet, a Belgian, broke the world's record for a flight with a passenger here to-day. With a companion he rose in an aeroplane and remained in the air for 2 hours and 20 minutes. The best previous record was made by Effimoff on a Farman biplane at Mourmelon January 30; his time being 1 hour and 50 minutes. Kinet is a comparative novice in aeroplaning.

AVIATION MEET AT MINNEAPOLIS

MINNEAPOLIS, MINN., Apr. 4—Arrangements for a three-day aviation meet have been completed and the event will take place June 22-25 at the State Fair Grounds. The program includes contests for both speed and distance.

FOR MILE-A-MINUTE STOCK CARS

One of the special features of the National Championship track races at Indianapolis May 30 will be event No. 14, a race the conditions of which have been framed to test the claims made by makers of stock cars that their machines can travel a mile a minute under touring conditions, carrying four passengers.

John A. Wilson, of Franklin, Pa., has donated a cup valued at $150 to the winner of such a race. Under the rules the competing cars will be required to race a mile in one direction and then traverse the same distance in the opposite direction. In order to win the successful car must average at most a mile a minute.

Torpedo bodies and baby tonneaus are barred and the entrants must not rate higher than 50 horsepower, according to A. L. A. M. standards.

FIRST ENTRY IN ATLANTIC CITY RUN

The first entry for the two-day automobile reliability contest from New York to Atlantic City and return, which will be held on May 10 and 11 under the auspices of the Motor Contest Association, was made less than one hour after the official entry blanks were issued, when Mr. Merrill named Lewis Strang as the man who would handle his Pierce-Racine in the contest. Before leaving for Los Angeles, S. M. Butler, chairman of the Contest Board of the A. A. A., granted a sanction for the Jersey contest, and entry blanks have been sent out to a large number of individual automobilists in addition to the firms in the automobile business.

UP-STATE RELAY RUNS PLANNED

SYRACUSE, N. Y. Apr. 9—Automobilists of Syracuse and Central New York generally, are interested in the preliminary plans for a big relay club run, the first time an undertaking on such a scale has been tried hereabouts. The plan is to start from Syracuse on Saturday, May 28, and to carry a message from some well-known person to the autoists of Central New York.

From here the message will be carried to Auburn, to Cortland, to Ithaca, to Watkins, to Elmira, to Owego, to Binghamton, to Oneonta, to Cooperstown, to Richfield Springs, to Utica, to Rome, to Oneida and back to Syracuse.

HILL-CLIMBING MATCH AT ATLANTA

ATLANTA, GA., Apr. 2—As an aftermath of Atlanta's recent hill climb, there will be a match hill climb, best two heats in three, on the Stewart avenue hill next Saturday afternoon. The contestants will be Billy Oldknow in his Buick and W. J Stoddard in a National.

PRIZE FOR GLIDDEN TOUR RUNABOUTS

Runabouts and miniature tonneau cars entered in the 1910 Glidden Tour will compete for a handsome trophy donated to that class by the Chicago Motor Club. The trophy will be awarded to the runabout or toy tonneau making the best score.

Alden Sampson Merged in United States Motor

TRUCK and commercial car building on a larger scale is indicated in the absorption of the Alden Sampson Manufacturing Company, of Pittsfield, Mass., by the United States Motor Company. The Sampson company has been operating under a license of much breadth and scope and its terms are so framed as to give additional latitude in manufacturing to the U. S. Motor Co.

The Sampson Company was founded by Alden Sampson many years ago. He was a man of wealth and a mechanical trend of mind, and he expended a vast amount of money and energy in prospecting the field of the commercial vehicle. The results of his work have been material and valuable, but when he was on the threshold of realizing them, he died, about a year ago. The active head of the company has been Guy E. Mitchell, general manager.

One of the secrets of the success of the Sampson truck is the fact that it has been kept entirely distinct from pleasure cars. The materials used have been special materials, fitted to the requirements of the truck in contradistinction to the pleasure car.

According to the announcement of President Briscoe, it is the company's intention to manufacture a wide line of commercial vehicles and in conformance with that policy, the Pittsfield plant will be considerably enlarged and improved.

Alden Sampson Plant at Pittsfield, Mass., Which Has Just Passed to U. S. Motor Co.

Auspicious Opening for Elmira's Automobile Show

ELMIRA, N. Y., Apr. 9—What is probably the last of the shows in New York State for this season, opened here this evening in the Third Regiment Armory, to run for a week. The show is directly held under the auspices of the Chamber of Commerce, assisted by the local Automobile Club. The opening was most auspicious, with a large crowd in attendance.

There are thirty exhibitors in all, showing a total of forty cars, with thirty-six different makes represented. In addition to this there is a good showing of accessories, motorcycles and bicycles.

Charles Teasdale of Elmira, is showing for the first time in public an aeroplane of his own invention.

List of Exhibitors:

Chenango Motor Sales Co., Speedwell; L. D. Woodward, Ford; R. C. Pierce & H. K. Spaulding, E-M-F, Flanders "20," Haynes; J. F. Rhoades, Jackson; O. D. Eisenhart, Winton; La France Motor Car Co., Velie, Hudson, Chalmers, Reo; International Harvester Co., I. H. C.; C. W. Bishop Co., Buick; Frank Record, White (gas); Elmira Motor Car Co., Maxwell, Empire, Franklin; Corning Auto Exchange, Peerless; Thomas Motor Co., Thomas; State Line Motor Car Co., Oakland; Roberts & Son, Rambler, Krit, Buffalo wagons; Corning Auto Co., Pierce-Arrow; Southern Tier Motor Co., Marion, Overland, Courier; F. C. Tomlinson, Insurance; J. M. Tillman, Accessories; W. B. Hallock, Clothing; Elmira Arms Co., Accessories; S. F. Izzard, Clothing; C. A. Georgia, Electric Supplies; P. B. Rutan, Motorcycles & Bicycles; D. S. Andrews, Trucks; Barker, Rose & Clinton, Tools & Supplies; C. W. Young, Bicycles; Leon A. Peters, Motorcycles; M. A. Van Brunt, Kellogg Pumps & Pressure Indicators; Roberts & Son, Accessories.

At Elmira's Show—General View on the Main Floor. At the Right, Scene Along One Main Aisle

Chalmers Thirty, Official Pathfinder for the Glidden Tour, Gardham at the Wheel, as It Appeared Before the Start

1910 Glidden Pathfinding Car Starts Trip

OFFICIAL pathfinding for the Glidden Tour of 1910, started Monday from Cincinnati. The pathfinding car, a Chalmers 30, is in charge of Dai H. Lewis. Joseph Gardham is the driver, and Lazarnick, the official photographer, accompanies the expedition.

The course of the tour through Lexington, Ky.; Louisville, Bowling Green, Nashville, Florence, Ala.; Memphis, Helena, Ark.; Little Rock, Texarkana, Dallas, Tex.; Oklahoma City, St. Joseph, Mo.; Wichita, Kan., through Iowa to Chicago, will require twelve days according to schedule, and will be approximately 2,500 miles long.

The tour upon which Mr. Lewis and his companions have started will require considerably more time than the run itself. This is due to the fact that the roads have to be carefully charted and mapped en route. It is expected that about three weeks will be spent on the road.

The selection of Mr. Lewis for this important duty came to him unsought. He is particularly busy at this time of the year with the affairs of the Buffalo Club, of which he is secretary. Four times prior to this year he had charge of the pathfinding trip of the Glidden Tour, and his labor in this respect has brought him much praise.

The Buffalo Automobile Club granted him leave of absence for this purpose on the highest ethical basis. The club realized that the performance of such a mission by one of its officers was a service to automobiledom generally, and was fully cognizant of the honor that must redound to the club for its part in furnishing such an important detail of the big tour.

INDEPENDENT AUTO SHOW ANNOUNCED

The Journal Company, of Troy, N. Y., by C. C. Conant, president, announces that the Eleventh Annual Automobile Show will be held at Grand Central Palace, New Year's Eve. 1910, continuing until Jan. 7, 1911.

According to the literature sent out by the Journal Company the show is intended to afford independent automobile manufacturers an opportunity to interest the motor-buying public. Space will be allotted in the order of the receipt of applications.

Referring to the announcement of an independent automobile show at Grand Central Palace at the opening of next year, Alfred Reeves, manager of the A. L. A. M., had little to say.

"Exhibitors of motor cars and motor accessories at the show outlined," said Mr. Reeves, "will be automatically barred from participation in the Chicago show and other exhibitions under the rules of this association."

CROWDS AT HARRISBURG OPENING

HARRISBURG, PA., Apr. 11—The first annual automobile show under the auspices of the Harrisburg Dealers' Association was opened in Kelker street Hall Saturday, with all space taken and 52 cars, representing 32 makers, on exhibition. The large hall has proved not large enough to accommodate the dealers, and several private displays are being held by agents who were unable to secure floor space.

NEW OFFICERS SELECTED FOR A.C.A.

Officers for the Automobile Club of America were elected Tuesday night at the annual meeting of the organization at the club house, 247 West Fifty-fourth street, New York city. There was only one ticket nominated, which was as follows.

President, Henry Sanderson; first vice-president, John E. Borne; second vice-president, Robert Lee Morrell; third vice-president, Edward Shearson; treasurer, Finis E. Marshall; three governors to serve four years, Dave H. Morris, Albert R. Shattuck and E. H. Gary; governor to serve in place of Cornelius Vanderbilt, two years, Alfred Ely; governor to serve in place of Horace Porter, three years, George Moore Smith.

ECONOMY RUN TO LAKE GENEVA

CHICAGO, Apr. 11.—Sanction has been granted the Chicago Motor Club by Chairman Butler of the contest board of the A. A. for an economy run April 28 over a route from Chicago to Lake Geneva by way of Halfday, a distance of 200 miles.

BENZ-FIAT MATCH RACE DECLARED OFF

LOS ANGELES, Apr. 13.—The match race between the Benz and Fiat cars, Oldfield and De Palma, drivers, has been declared off. The Fiat car broke a piston again, and announcement of the cancellation of the race was made at once.

NEW PIERCE-ARROW FACTORY ADDITIONS

(*Continued from page 709*)

Since the Fall of 1909 ground has been broken almost every month for some additional structure fitting into the total long ago provided by the designers. First to be completed was an addition to Machinery Hall, one story in height and 75 by 204 feet plan. Closely adjoining stands a new L-shaped building, one wing 61.5 by 305 feet and the other 50 by 100 feet, both four stories in height. On the first two floors raw material and some finished stock are stored, and the two upper stories are to be used for the assembling of motors, transmissions, rear axles, carbureters, pumps, steering mechanisms and clutches. The storage floors in this new building release one end of Machinery Hall which has been used for storing of raw material, and this space as well as the side of the hall, heretofore used for inspection work, will be cleared for the installation of new machinery. This will result in a machine room believed to be larger than any other under one roof in any industry in North America.

The upper stories in the new L at the same time place 50,000 square feet of floor space on one level at disposal for painting and assembling of chassis alone. This work has so far been done, together with the assembling of construction units in one great hall, 400 by 122 feet, and the removal of the unit work to the new L therefore serves both for enlargement and improvement of the system.

Two new wings, each 350 by 50 feet and four stories high, are approaching completion and are joined at one end by a building, 40 by 50 feet, three stories high. Added to the adjoining older structures, the whole complex measures a total length of 750 feet, and the new space is to be given over to the body makers, with a view to continuing the company's policy of placing a large number of different bodies, suited for all automobile purposes, at the disposal of motor car users. Not less than 7 1-2 acres of floor space will be available for body building when the new wings are completed.

Other additions to the Pierce-Arrow industrial city on Elmwood avenue are a nickel-plating house, 61.5 by 184 feet, four stories, now in course of construction, an addition to the motor-testing department, 55 by 200 feet, one story high, and an addition to the power house, 51 by 50 feet, one story high, together with a new smoke-stack, 150 feet high, and with the firm's name inlaid in colored brick, so he who motors may read it without stopping.

Two more buildings are planned. One of these will be used for the manufacture of the new heavy motor truck. It will be 184 by 300 feet and four stories, of reinforced concrete like the other new buildings. The other is to be an extension of the office buildings, 68 by 220 feet, and three stories high.

The total floor space of the enlarged plant will reach 1,000,000 square feet or 23 acres. The boiler capacity has been increased 2,000 horsepower, partly by the attachment of "economizers." One new 1,000-horsepower engine has been installed. Most of the new machine tools for the vacated space in Machinery Hall have already been put in place, and the force of 2,600 employees is being daily increased.

ADVANCED METHODS IN NATIONAL PLANT

(*Continued from page 711*)

ground. C, in the same illustration, presents a heavy and well-designed radial drill, which, together with its fixtures and jigs, becomes an important member in the train of machine tools employed in the aluminum crankcase work.

In a general way, the jigs and fixtures as they are employed at this plant, are designed on the same common basis. The idea is to afford to the workman a means by which he will be enabled to take the rough or partially machined parts, place them in the fixtures and proceed with the operations without having to go through the laborious process of setting up the work. Fig. 2 shows one of these fixtures as it is used on a heavy milling machine for the purpose of reaming out the two ends of the connecting rods. The jig G rests on the platen T and the reamer R is guided by the bushing B into the large end of the connecting rod C. The other end of the same fixture has a smaller bushing which registers with the gudgeon-pin end of the connecting rod. These hardened bushings are screwed into the fixture, and by changing the bushings it is possible to use the fixture, first for roughing out, and second for reaming, so that the amount of metal to be cut from the walls of the bore in each case is of equal radial thickness and the tendency of the reamer to back away at some one point in the diameter is thereby eliminated. The fixture is so designed that the workman is not held responsible for the accuracy of the undertaking, because the centers are fixed, and the reamers or other cutting tools are properly sized in the tool room, thus putting this part of the accuracy question up to experts who have no other duty to perform.

As an illustration of a more complex situation reference may be had to Fig. 3, which shows a fixture F on a horizontal boring tool with a platen P, which is provided with a cross feed, and the fixture in this particular case is one which holds the bevel-drive housing H for the rear axle. The illustration so clearly presents the situation that it seems almost unnecessary to go into a further description, excepting to point out that the horizontal boring mill is especially designed for the accommodation of work of this character; the alignment is most thoroughly established and the vertical distance from the face of the platen to the axis of the boring bar is dependent entirely upon the accuracy with which the jig was made. Here again is evidence of a plan which assures the greatest measure of accuracy. It is the accuracy which comes from utilizing toolmakers of accentuated skill in the process of producing the jigs and fixtures, which makes it unnecessary to consider the skill of the machinists who do the regular work, beyond the barest measure, which is involved in the mere use of the fixtures in the regular way, remembering that they cannot be employed, excepting as designed for the work.

POINTERS IN VALVE REPAIR WORK

(*Continued from page 715*)

trouble, and this may be proof of the lack of necessity of adjustments at this point. The ends of the valve stem and the lift were found to be substantially glass hard, and on the whole it seems that on a non-adjustable valve motion is capable of rendering service for at least three years, without seriously discommoding the owner of an automobile. There is no getting away from the fact, however, that when the evil day arrives the problem involved is one which is difficult to surmount. Fig. 8 shows a system for the valve motion in which provision is made for adjusting, and a non-metallic pad is placed in the head of the adjusting stud for the purpose of deadening the sound. The amount of noise generated by this system is relatively slight in view of the use of a smaller diameter roller, which has the good effect of reducing the clearance requirement. It is fairly appreciated in designing quarters that the diameter of the roller is the influencing factor when the amount of the clearance is to be determined.

The very fact that the wear is not equal, and that the valves do not grind down at the same rate, is ample reason for desiring an adjustment, if it is true that adjustments can be so made that they will not rattle loose. It is not easy to provide an adjustment which will serve for a reasonably long time without undoing, and many designers prefer to take their trouble the other way. It might be well to bear in mind, however, that the other way is the method by which the trouble is transferred to the owner of the automobile after the designer gets through with it. If, in the design, the trouble is three years remote, there is not so very much to complain about, but purchasers of automobiles at the present time are trying to reach the conclusion that the life should be more than that as indicated by a 33 1-3 per cent factor of depreciation. Ten per cent should be a large enough depreciation factor in modern manufacturing

AMONG THE GARAGES

Grabowsky truck, run by the Motor Car Maintenance Company, of New York City, in the service of the New York branch of the Continental Caoutchouc Company, loaded with rims

John W. Bate, designer of the Mitchell-Lewis Motor Company

An organization of garage owners and managers is being discussed with much interest in some parts of Automobile Row. In referring to the possibility of such a movement, Edward G. Koerner, manager of the Pyramid Garage, 36 West Sixty-second street, said that he was in favor of such an organization. Mr. Koerner said that there was too much irregularity in prices of storage and supplies and that better service could be furnished to the motoring public if an agreement could be reached about an equitable price level. A preliminary meeting at which the project will be presented may be called in the middle of April.

There is considerable agitation against an ordinance pending in the City Council relating to the future establishment of garages in Indianapolis. Should the measure become a law, except in a district bounded by Alabama, Georgia and New York streets and Senate avenue, a garage cannot be established in the same square with a church or school building, while in any other square the written consent of a majority of the property owners must be obtained and also the written consent of all persons owning property within 50 feet of the proposed garage.

Uniontown, Pa., is getting right to the front as a user of automobiles. About 200 are now owned in the town. There are four large garages in Uniontown, the Standard on Peter street, the Keystone on Mill street, the Central on South Gallitin avenue and the Uniontown on East Fayette street. It is estimated that fully $700,000 is invested in automobiles and garages.

The Greensburg Automobile Company now has the largest and most complete garage in Western Pennsylvania. The floor space of the company is over three-fourths of an acre and gives it extended show room. W. H. Sharpe is manager, Elmer Turner is sales manager and Curtiss Clawson is floor manager of the firm.

E. D. Crane & Company, of Atlanta, are building a garage in the rear of their present plant at 44 Madison avenue. The new building will be of stone and concrete and will add considerably to the efficiency of the concern in handling both gasoline and electric cars.

The Pilot Garage & Supply Company, of Worcester, which is one of the largest garages in Massachusetts, has made an assignment for the benefit of creditors. It is given out that the liabilities are $20,000 and the nominal assets are between $12,000 and $15,000.

Chauncey R. Benefield, Robert T. Lamb, Gordon Frierson and William Percy have organized and incorporated the P. D. Q. Company, of Shelby County, the company being capitalized at $6,000.

The garage of the Empire Auto Repairs Company at Spokane, Wash., will be ready for occupancy April 15.

It is estimated that the up-keep of motor cars in New York State in 1909 was about $97,000,000, and in the natural order of things it will be considerably more than $100,000,000 in 1910.

The Globe Garage & Auto School, of Pittsburg, has been organized by Ralph F. Worden, D. P. Reighard and A. J. Schmitt of that city and has applied for a Pennsylvania charter.

A modern garage will be erected in Spokane, Wash., by the Empire Auto Repair Company, on Second avenue, near Cedar street. It will be 50 feet wide by 100 feet deep.

F. D. Palmer, 239 West Fiftieth street, will add a line of second-hand cars to his garage and repair shop about April 10 and will take up renting on a larger scale.

At Circleville, the Spangler Automobile Company will soon open a garage on North Court street. The building will cover a half lot and will be two stories high.

Harvey Steel and Craig Humgardner of Punxsutawney, Pa., will build a garage 116 by 62 feet at once and have secured the agency for two well-known cars.

A concrete garage for the North Shore Garage Company, New York avenue, Huntington, L. I., is being built under the direction of Franklin Baylis, architect.

The Portage Motor Car Company, of Akron, O., was incorporated with a capital stock of $5,000 to operate a garage by Albert Buehrle and others.

Joseph C. Strout has bought the lot and building at 242 West Twenty-seventh street, New York city, and will alter the present building into a garage.

A. C. Woodbury, of Springfield, Vt., is building a garage 40 by 48 feet in that city. The improvement contemplates a repair and supply department.

At Massillon the English Motor Car Company has purchased the Loeffler block on South Erie street, which will be remodeled into a garage.

Harry Henderson has opened a new garage on Canal street, Greenville, Pa., and has secured the agency for two well-known cars.

Permit has been issued to the Northern Garage Company, of Philadelphia, to build a $6,000 garage on Cabot street.

The Philadelphia Construction Company has opened a garage at 227-229 Raymond court, Scranton, Pa.

The Washington Garage Company has been incorporated to conduct a garage business in The Bronx.

In Urbana, Ill., a new garage is under construction for the Illinois Motor Sales Company.

The Philadelphia Construction Company has opened a garage at Scranton, Pa.

WITH THE AGENCIES

Large shipment of Studebaker electric delivery wagons, made to the big department store of Gimbel Brothers, New York City, which will use these for delivery exclusively

Emerson Brooks, now president of Rothschild & Company

Boston's great show four weeks ago convinced the Standard Automobile Company that the Hub city needed Paterson "30's" and lots of them. The result was a large contract between that hustling agency and the manufacturers, the W. A. Paterson Company, at Flint, Mich.

Through a deal which was closed recently, the Studebaker branch of Columbus, O., has taken over the business of the Burdell Auto Sales Company, of North Fourth street, Central Ohio agents for the E.-M.-F. and Flanders "20."

The Grout Automobile Company, of Manchester, N. H., has been organized to handle new cars and a general garage business. The company will assume the agency for the Grout car throughout New Hampshire, exclusive of Cheshire County.

Charles E. Riess & Company, New York and New Jersey distributors of the Marion and Overland cars, have entered a 35-horsepower Marion Roadster in the 24-hour race that is scheduled to take place early in May at Brighton Beach.

H. M. Adams, sales manager for the Royal Tourist Car Company, Cleveland has just appointed two agents. These are the Lock Haven Auto Company, Lock Haven, N. Y., and the La Crosse Plow Company, La Crosse, Wis.

The New York allotment of Pope-Hartford cars has been practically sold for this season. At the company's garage it was said that only twenty cars remained to be disposed of. Trade in used cars is reported lively.

H. R. and L. L. Applebaum, agents for the Detroit Electric in Cleveland, have accepted the agency for the Herreshoff car. Applebaum Brothers moved to larger quarters in automobile row April 1.

James E. Graham has secured the Pittsburgh agency for the Coleman automobiles and has established headquarters at 807 Westinghouse building.

The Kittanning Automobile Company has been formed at Kittanning with a capital of $5,000 by James A. McMasters and others of that place.

The Western Sales Agency Company of Cincinnati, was incorporated with a capital of $5,000 by Max S. Goldsmith and others.

The Park Automobile Company, of Johnstown, Pa., has been formed by F. J. and E. L. Erwin and Bruce H. Campbell, of that city.

The Athens Automobile Company, of Athens, O., was incorporated with a capital of $10,000 by A. T. Lawhead and others.

The New England Garage Company at 232 Main street has taken the Hartford agency for the Cutting 40.

The East St. Louis Automobile Company, of East St. Louis, Ill., has taken the agency for the Jackson.

A Franklin agency has been established at Altoona, Pa., with Mozer & Lapp, a new firm in that city.

The Bayless Motor Car Company, of Lexington, Ky., will represent the Jackson in that territory.

The Cooper Automobile Company, of Birmingham, Ala., has taken the agency for the Jackson.

E. L. Beal, of Republic, Mo., will handle the Jackson for 1910.

Brief Personal Trade Mention

Emerson Brooks, for twenty years vice-president of J. M. Quinby and Company, Newark, N. J., has resigned and it is announced that he has bought a half interest in the Rothschild Company of which he will be president and general manager. It is said that the Paris connection will be strengthened and the business field of the company made broader.

Surrounded with floral beauties and in the presence of a large gathering of their friends and relatives, Miss Edythe May Meeks and Charles Ernest Easton, of Munice, Ind., were married recently at the Meeks residence in that city. Mr. Easton is advertising manager for the Inter-State Automobile Company. The young couple will be at home after May 1.

Lazarnick, the well-known automobile photographer, has been appointed to take the pictures on the 1910 Glidden pathfinding trip by the Chalmers Motor Company and the A. A. A. He has served in a similar capacity on five of the six preceding pathfinding trips. This work is particularly important and his past efforts along this line have met with approval.

Harvey H. Colbath, manager of the Philadelphia branch of Morgan & Wright, and Helen V. Cadwalader were married in Philadelphia April 7. After the ceremony the bride and groom left on a trip to Washington, D. C., and other points South.

A. D. Youmans, who was lately with Studebaker Brothers Company, of New York, as salesman in their commercial vehicle department, is now connected with Renault Freres Selling Branch, Inc., of New York City, in a similar capacity.

Ralph N. Harris, formerly connected with the Jeffery Manufacturing Company of Columbus, O., and now an attache of the city waterworks department, has applied for a patent on a new automobile bumper.

M. A. Weissenburger, for several years superintendent of large department stores in Cleveland, has accepted a position with the Regal Motor Sales Company, Cleveland, and will assist Manager J. C. Hipp.

A. L. Englander, formerly with the Buick Motor Company at Cleveland, has joined the sales force of the Cook Motor Sales Company, Ohio, agents for the Premier and Reo lines.

Gridley Adams, advertising manager of the Dayton Motor Car Company, in his flush-sided Stoddard-Dayton runabout

H. S. Firestone, president of the Firestone Tire & Rubber Co.

Ground has been broken for a large addition to the plant of the Locomobile Company of America at Bridgeport, Conn., which will mean the employment of 250 more hands and facilities for manufacturing 300 more cars each year. This structure will be erected just east of the present buildings and be known as Factory No. 3. This new building will be four stories high, 150 feet long and 50 feet wide. An addition of one story will also be placed over the forge shop in use at present. The contract calls for completion of the work in four months.

Work has been started on the first of the twin buildings for the Regal Motor Car Company, Detroit, which when finished will occupy an entire block. The structure now under way is 582 by 167 feet, two stories in height, of reinforced concrete, and contains many novel features. Among these is a circular driveway which goes entirely around the interior of the building on both floors, with elevators of sufficient strength to raise a loaded truck.

The Saurer Motor Trucks, organized to manufacture and deal in motor vehicles and accessories, has filed articles of incorporation at the office of the county clerk. The authorized capital is given as $1,000,000, of which $1,500 is paid in. The registered office is at Knollcrest, Hilton Park, West Orange, N. J. The incorporators are: William D. Sargeant, West Orange; George M. Judd and Edward H. Fallows, of New York.

Columbus stockholders in the Oscar Lear Automobile Company, of Springfield, O., have been informed that the receivership was dissolved and the new company, to be known as the Kelly Motor Truck Company, will have entire control of the plant. C. S. Kelly, president of the Commercial Club of Springfield, will be at the head of the reorganized company. The building of additions to the plant will be continued.

The board of directors of the General Motors Company passed a resolution of sympathy for the family of the late Harry G. Hamilton, a member of the board, who died at his home at Pontiac, Mich., last month. Broad tribute to the worth of Mr. Hamilton to the motor industry was paid in the resolution, which was ordered spread upon the minutes.

At a meeting of the stockholders of the Howard Motor Car Company recently the following were elected to the board of directors: Adam Howard, H. A. Pounder, W. J. Geer, H. Gottdiener, B. B. Gill, Frank Faber and Fred K. Beery. The site for the factory, which will be located at Galion, O., will be selected soon.

The Willard-Harlow Manufacturing Company, of Janesville, Wis., has elected these officers: President, R. Willard; vice-president, P. H. Korst; secretary, J. C. Harlow; treasurer, O. W. Athon. The company will manufacture spark plugs, meters, tops, canopies, awnings and other specialties.

New Zealand, Tasmania, and even the Fiji Islands are growing as a field for the automobile. The Hupp Motor Company, of Detroit, recently closed a contract to deliver 200 Hupmobiles to E. G. Eager, of Auckland, New Zealand, in 1910, several of which have been ordered by residents of the distant Fijis.

The James Kidney Motor Truck Company, of Cincinnati, was incorporated recently with a capital stock of $10,000 to manufacture automobiles, motor trucks and delivery wagons. The incorporators were: James Kidney, W. W. Ramsey, W. A. Stuart, Frederick E. Clarke and Joseph Wilshore.

Captain William Mitchell Lewis, president and general manager of the Mitchell-Lewis Motor Company, Racine, Wis., and candidate for Governor of Wisconsin, will make another European business trip at once. He will return May 25, at which time he will open a vigorous political campaign.

The Vickers Auto Car Company, of Coshocton, O., has completed its first car, which will be called the Vickers car, and the test will be made in a short time. Carl Vickers is at the head of the company. The demonstrator is a two-seated runabout with a four-cylinder, two-cycle, air-cooled engine.

At Millersville, Ohio, the Millersville Machine Company is erecting a new plant, just east of the old factory, which will be used to manufacture automobiles. Recently a 25-horsepower runabout has been placed on the market. New machinery is to be added to the present equipment.

The suit of the Hess-Bright Manufacturing Company against the Standard Roller Bearing Company, based upon infringement of patents covering ball bearings, was decided in favor of the complainant company in the United States Court at Philadelphia.

The Kurtzer Radiator Company, of Cleveland, was incorporated with a capital stock of $10,000 to manufacture automobile radiators and other accessories, by Hugo P. Kurtzer, F. N. Dunsford, G. M. Phillips, L. D. Litzler and William F. Kees.

The Hupp Motor Car Company, of Detroit, has increased its capital stock to $250,000. A factory agent of the company has been commissioned to attend the Brussels and Berlin expositions this Summer. He will establish agencies for the car abroad.

The Northway Motor Company, Detroit, will build an addition three stories in height, 225 by 90 feet, with two wings, each 175 by 60 feet. This will involve an expenditure of $100,000, triple the capacity, and permit the employment of 2,000 men.

The Schurmeier Motor Car Company, of St. Paul, Minn., recently has been organized with capital stock of $200,000, to manufacture automobiles and other vehicles. Frank I. Whitney was named as president of the company under its charter.

Vice-President and General Sales Manager Horace DeLisser, of the United States Motor Company, was the guest of honor at a dinner tendered by branch managers, salesmen and officials of the Ajax-Grieb Rubber Company at Delmonico's.

The Cleveland Speed Indicator Company, of Cleveland, has been reorganized, and J. W. Hopkins chosen president and G. W. Cook, secretary.

Exterior of the White Garage on West End avenue, New York City, both the six-story and the three-story buildings being utilized

Interior view, being a scene on the third floor, where cars are stored and some repairing is done. The machine shop is on this floor

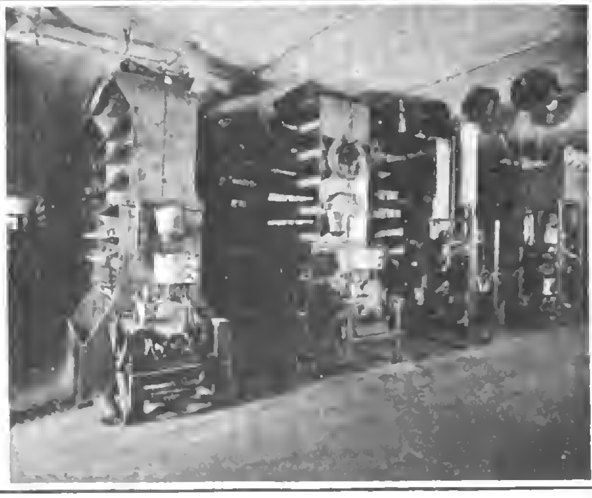
Prominent New York City Garages—White

THERE are many garages in New York City, but among those entitled to first rank, the garage of the White Company, located at 205-213 West End avenue, is as worthy of complete description as any. This consists of two buildings, used as one however, one six stories high and the other but three stories in height. Each building has a basement. The higher building measures 44 feet wide by 93 feet deep, while the lower one has a width of 49 feet and the same depth, all inside figures.

The space is well allotted to the various departments so as to secure the best results with the available floor space, the wbole capacity being well in excess of 125 cars live storage and 50 cars dead storage. The number of employees at the present time is in excess of 80, this figure including a staff of bookkeepers.

On the ground floor the whole space of both buildings is given over to live storage, with the single exceptions of the offices and check rooms for material or clothes left in the cars. The basement below is also used for live storage, except 20 feet width clear across the front, in which are the employees' lockers in one building, and the chauffeurs' rooms, in which are the lockers and a well-equipped poolroom. On the second floor the front end accommodates the accounting department, the one building the stockroom, and the other has live storage for 30 cars. Going on up, the fourth and fifth floors are exclusively dead storage, barring only a small testing room in the rear of the fourth, which also communicates with a testing room on the roof of the smaller building, where the generators are tested.

Machine shop of the White Garage, located at the front of the third floor, and well equipped with machine tools and workmen



View in the stock rooms on the second floor, showing the large number of White parts on hand and the orderly arrangement

Fig. 1—Parts of the synchronous coil of Bosch Dual Ignition System dissembled to show construction.

Bosch System of Dual Ignition for Automobiles

SOME years ago, in an endeavor to give their cars greater reliability, several automobile manufacturers equipped their engines with two complete systems of ignition. This practice did not become general, however, for through the heavy carbon deposits from the oils then in use, the lack of adaptability of the plugs for the service, and through individual characteristics of the engines, the set of plugs not in use showed a tendency to become foul and was not capable of operating when the necessity arose. The practical method of overcoming this difficulty was to arrange for both magneto and battery ignition, with a single set of plugs, and this was accomplished by the production of the Bosch "Dual" System.

In the Bosch "Dual" System, the magneto generates its own direct high tension current, while the battery circuit is entirely distinct, and utilizes a separate coil, but with individual breaker.

Except for the distributor and plugs, the systems are independent, with the result that the ignition will not be interfered with by an accident to either. On engines where but one spark plug location can be provided, and a timer drive cannot be arranged, the Bosch "Dual" System is producing results.

Recent years have brought great improvements in oils and spark plugs, with the result that ignition systems previously judged impracticable are to-day giving satisfactory results. Certain automobile manufacturers, who for technical and personal reasons, favor the use of two independent systems, have proved that under modern conditions, such an arrangement is entirely practical for engines in which a timer drive and location for a second set of spark plugs can be provided.

The Bosch battery system is used in connection with any of the standard Bosch magnetos, and consists of a combined timer and distributor, and a synchronous coil of special construction.

Fig. 1 illustrates the parts of the synchronous coil, which may be withdrawn by the removal of a single screw; these parts are the housing, the brass cover, the synchronous coil itself, the stationary switch plate, and the rear cover that protects the connections. The synchronous coil is similar in every way with the armature of the magneto, so that there is no difference in the ignition that they produce. The windings are of heat-proof enameled wire, the layers being insulated with a special fabric. The magnetic field is rendered more than usually complete by the use of laminated and divided soft iron end-plates. Built into the lower part is a heavy fibre block in which are imbedded the movable switch contacts, and in operating the switch, the entire synchronous coil is rotated inside of its housing. The switch presents four combinations; the off position, and three running positions which permit operation on the battery alone, on the magneto alone, or on the battery and magneto, together with both sets of spark plugs in use.

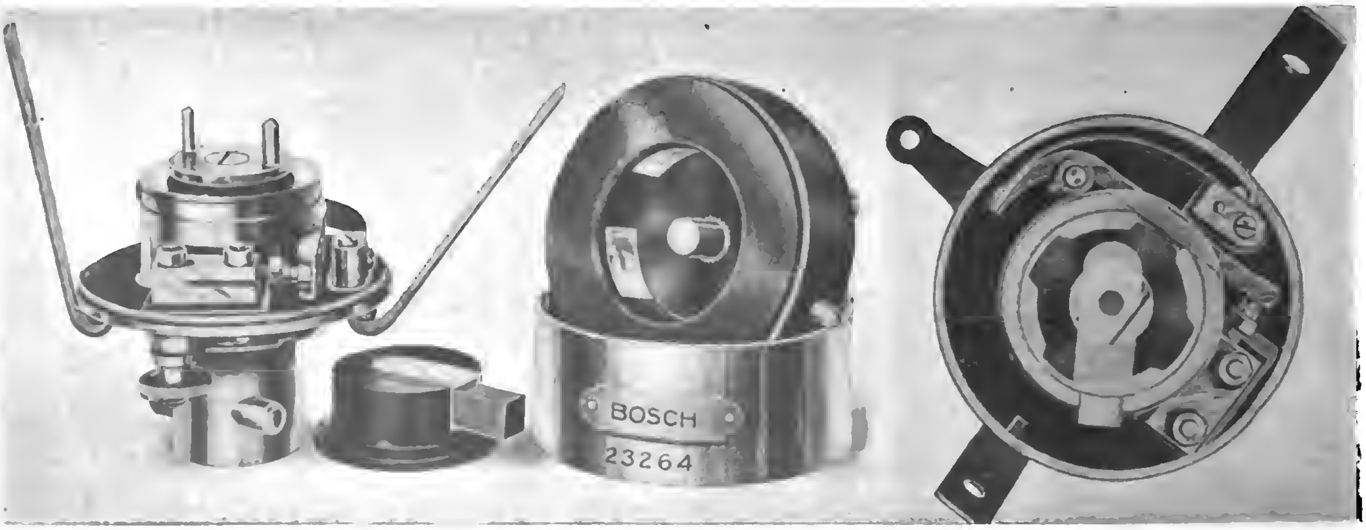


Fig. 2—Timer-distributor parts, partially dissembled. Fig. 3—Contact breaker and cam, with operating lever of sheet metal

THE AUTOMOBILE

THE OTHER HALF OF THE AUTOMOBILE

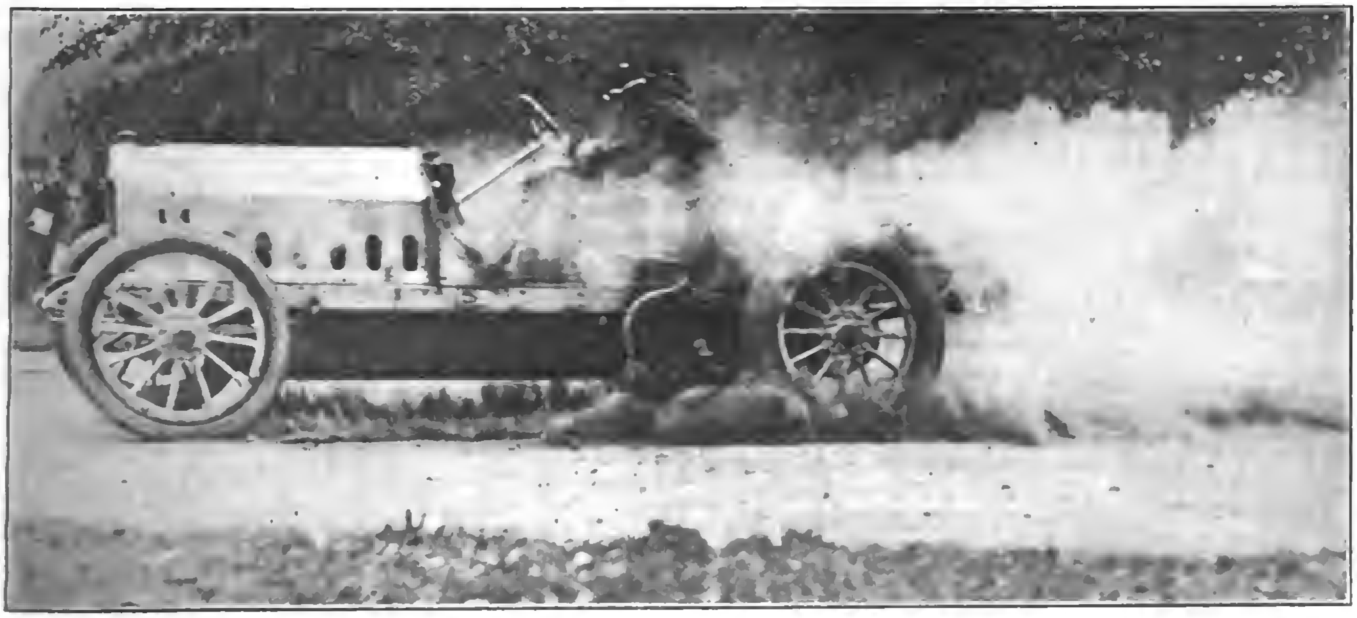
GENERALLY speaking, a medium for transportation comprises a vehicle and the track on which it rolls. Referring to a train of cars as drawn by a locomotive, it is a self-evident fact that the roadbed and the rails constitute a very essential proportion of the system. In railroad work, service is improved in proportion to the advances made in the qualities of the roadbed and the rails. Improving the trackage improves the service, and when it was found that locomotives had substantially reached the limit in response to human ingenuity and activity, further headway was obtained by increasing the weight of the rails per unit of length, and improving the qualities of the ballast used on the roadbed.

Likewise, in considering an automobile, the practical performance of the car will depend upon the degree of perfection of the roadbed. In a sense, increasing the utility of the automobile may be accomplished in one of two ways, i. e., adding to the roadability of the car, or improving the road. In view of these considerations, it is not far-fetched to point out that the roadbed is the other half of the automobile, so to speak.

Since the roadbed serves for a large number of the machinery components, wisdom would seem to indicate that it should be improved at any cost. Trying to make machines (automobiles) so that they will render good service on bad roads is an undertaking which violates every principle of national economy. It is perfectly foolish to suppose that the public at large may avoid paying for the extra work which will have to be put upon the automobiles to make them render efficient service on inefficient roads.

If it is assumed that automobiles (the machinery portion) can be built for $1 per pound, it may at once be said that the roadbed will cost but a minor proportion of this price per pound. The machinery portion is only available for one specific utility purpose, but, as before stated, the roadbed is available for the common use of all the automobiles. To sum up from this point of view, the public at large, who must pay for the automobiles and the roads on which they run, might better settle for good roads than to pay $1 per pound for automobiles.

If there are 300,000 automobiles running in this country at the present time, and if they weigh 2,000 pounds apiece, taking this as an average figure, the public at large must have expended $600,000,000 in the purchase of the automobiles. There are numerous important considerations which do not come out in the mere statement of the purchase price of a given number of automobiles. If the depreciation due to roads as they obtain at the present time is equal to 20 per cent. the public at large must pay $120,000,000 per year in the maintenance of 300,000 automobiles.



RACING SCENE SHOWING HOW CARS AT HIGH SPEED TEAR UP THE ROAD SURFACE

Improving the road has the effect of decreasing the first cost of the cars, and the further effect of decreasing the cost of maintenance thereof. It is useless to go into figures to express the savings which will result if the roads are made uniformly good, but the situation as here presented, while it fails to tell the whole story, very clearly indicates the advisability of improving the roads in order to save money on the whole.

The discussion may be advanced to a high economic phase in the simple process of pointing out that in the transportation of goods, if time can be saved, a saving of money will result also. If money is worth 6 per cent. per annum, and it must be, since most of us will take all we can get at that price, a saving of money will result if goods are transported at a saving of time. Goods tied up on the road represent money drawing interest; lowering the tie-up time reduces the interest charge.

There are secondary phases to this same situation. If the delivery of merchandise is delayed, opportunity for its proper disposition will be lost. Failure to conform to a delivery contract indicates failure of the whole undertaking, whatever it may be, since little or nothing can be done until the merchandise is delivered. In this way, all along the line, speedy and inexpensive methods of transportation provoke additional advantage, and in counting an advantage it becomes necessary to account for the loss, if the advantage is neglected.

It is extremely difficult to bring the citizen at large to a proper realization of the fact that a commodity is at his expense, even though it may be purchased and paid for by his neighbor. An automobile is a luxury in the service of a class, according to the average citizen, if he does not own one, and a certain prejudice is prone to interfere with the process of normal thinking under the circumstances. Let it be taken for granted that the owner of the car in any given case realizes the direct result, but this fact in itself does not fix the character of the service, which in the ordinary course, may be efficient or

Indirectly, the service, if it is advantageous, becomes so for every one, or if it is inefficient, levies tribute from all. Broadly speaking, then, it is the duty of every citizen to wisely provide for the roads which will help in the process of transporting merchandise, and thereby reduce the total cost of the service as rendered, in order that the proportion of cost, a percentage of which is bound to fall upon every citizen, will be minimized.

Since the roadbed serves in common for all the automobiles available for use, it is ample indication of the necessity for doing the best possible work in its construction. An inferior road will induce excessive depreciation in a superior car, but it must be perfectly plain that even a well-built road is likely to suffer from the severe service to which it falls heir in view of its common use by all automobiles.

The front page illustration shows a racing car on a macadam road, and as a result of the superior ability of the car and the inferiority of the road, its performance denotes rapid deterioration, which is evinced by the cloud of dust raised. Contrary to the statements which are frequently made, even the front wheels pick up the top dressing of an inferior road when the speed of a car is high, although, as the illustration further portrays, the rear wheels have the most marked effect, which is no

doubt due to the transmission of power at the point of load contact of the driving wheels.

From the point of view of the automobile proper, the amount of damage which can be done is proportional to the amount of energy which is wasted at the point of the transfer of same. When an automobile throws up a cloud of dust, it is claimed, as a rule, that it is destroying the roadbed, but looking at it from the other point of view, rather leads to the contention that it is merely disposing of the dust which must have been there at the time. What is wanted is a roadbed, the surface of which is so closely bound, and so thoroughly in keeping with the service conditions that dust will not be manufactured. The very binder which best serves for the purpose is the one which will abort dust formations. It will also defeat undue tire depreciation, because the transfer of energy at the point of contact of the tire with the road will be more efficient.

In a general way, the whole situation will receive an impetus in the right direction when roads are improved on a basis of the superior service which they will render with automobiles, rather than to continue to try to get along with roads which were formerly sufficient (if they were) under the conditions involving the use of animal-drawn vehicles.

Roman roads have lasted from a date 600 B. C., which goes to show that the Roman construction is more nearly in accord with our present needs than the macadam or telford work of our time. It is not necessarily the traffic which is at the bottom of the undue depreciation of the average road, and the very fact that some of our modern roads scarcely survive a single winter bears evidence of the ability of Jack Frost to upset the short-sighted plans of the taxpayer who grudgingly doles out the least possible amount of money for road building purposes, and in his disgust at having to pay anything at all, abandons the whole project, including his petty contribution, to the road building representative of the government, which in turn, becomes the victim of the contractor.

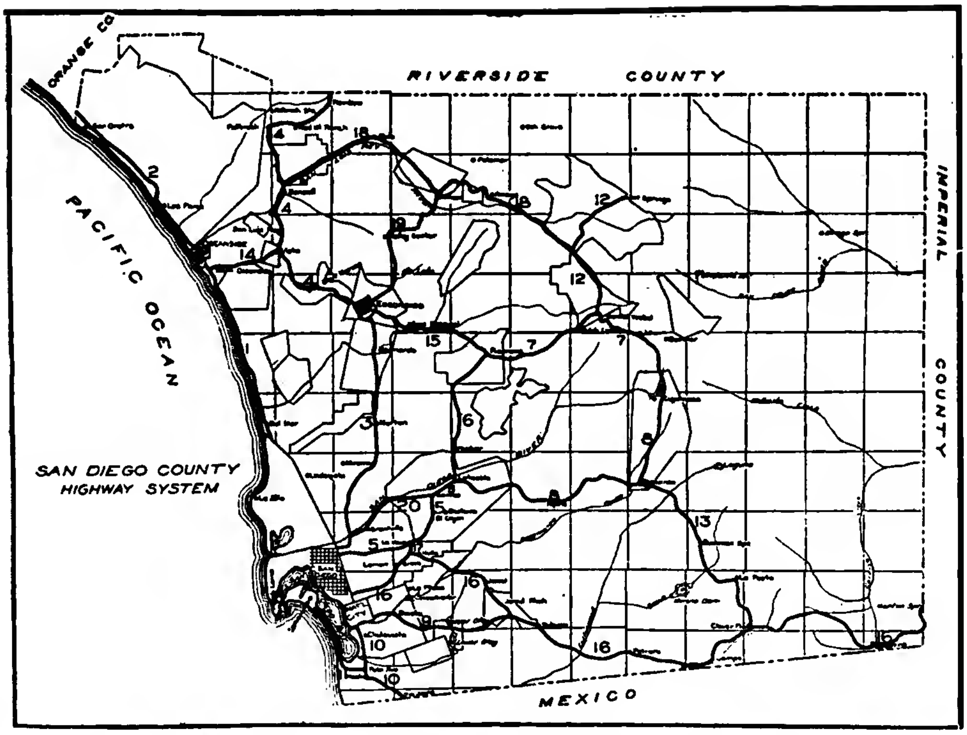
Taxpayers must first be made to realize that they will be the gainers if the roads are improved, and they must be made to understand that they must pay the cost of good roads; but these requirements will not prevent them from taking an interest in the further effort; they might just as well supervise the undertaking and see that the cost has an equivalent.

As a sample of the work being done in road improvement, a map of San Diego County, Cal., is presented showing the proposed new work there. The total covers some 448.5 miles, estimated to cost $1,250,000, an average of $2,800 per mile, which figure should produce an excellent road. The roads are all num-

Kind of Bad Roads Last Year's Glidden Pathfinder Found

Sample of Bad Roads Coast to Coast Racers Found In West bered, and among them it will be easy to pick out any one. Thus, the longest route is number 16, San Diego to Imperial County, 77.4 miles to cost $227,960, this being at the same time the most expensive of the twenty roads laid out.

In the old art of road building, purely mechanical solidification by wedge joints between the elements of construction, and the shedding of water, were the objects sought. To this the new art, rendered necessary no less by the increasingly exacting demands of civilization than by automobile traffic, adds the requirement of adhesion of the hard substances of the road in a softer matrix, to reduce wear and dust formations, help out mechanical solidification and permit loosened material to find new and secure lodgement in the roadbed by the action of the traffic or by simple, inexpensive repair work, and adds also the requirement that the adhesive material shall bind whatever dust is nevertheless formed and prevent it from being drawn or driven into the atmosphere by the action of wheels and wind combined.



Map of San Diego County, California, Showing Road Improvement Work

Oil treatment has been narrowed down experimentally to repeated sprinkling with oils of asphaltic base which leave a binding residue, while all oils with a paraffin or naphtha base have been eliminated, as causing more mud, more odor, less binding and less durability. Oil treatment is applicable to earth, gravel, sand and stone roads, but not to clay surfaces, unless much gravel is admixtured. One of the most thorough oiling methods, producing the "petrolithic pavement" involves elaborate mixing and tamping of the surface to a 7-in. depth.

Treatment with emulsions purports economy of oil by combining it with soapy substance and water, easy application, absence of objectionable odors and immediate effectiveness. A number of different emulsions are commercially controlled, and each must be considered separately with reference to its action on the kind of road to which it is intended to apply it.

Solutions in water of calcium chloride or nitrate of soda, salt and lime or sand and soda fused, afford substitutes for sprinkling water and bind dust for a much longer time; but have no effect to reduce wear or dust formation.

Coal tar, as a material applied to finished roads, has been extensively used for broken-stone surfaces. The methods of application by spraying involve the use of pneumatic pressure for the spray nozzles, rather than heating of the tar. The most economical, because most thorough, use of coal tar is for the building of new roads, in which use it is mixed, instead of water, as a binder for pillar material and a paint for all crushed stone. Coal tar can be applied with success only in dry weather.

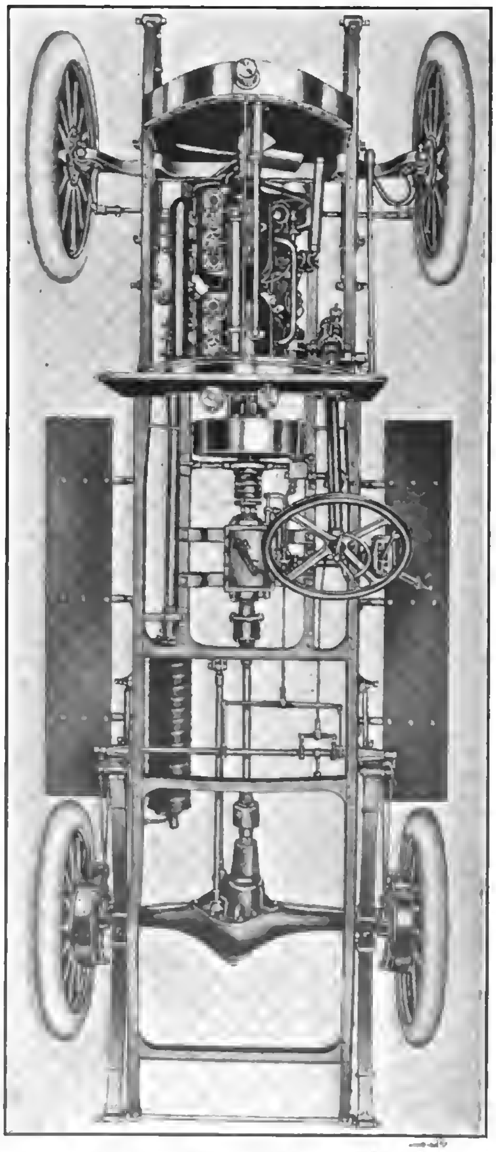
View of Torpedo Body Fitted to Speedwell Chassis, Showing Long, Rakish Lines

Manufacturers: Speedwell Motor Car Co., Dayton, Ohio

Motor, four-cylinder, 5 by 5 inches.
Cylinders cast in pairs, L type; valves on left side.
Water jacket heads separate, cylinder heads and valve chambers integral.
Crankshaft, drop forged alloy steel, with three plain bearings.
Camshaft, drop forged high-carbon steel, cams integral.
Crankcase, cast of nickel aluminum alloy, with wide flanges.
Ignition dual, Bosch high tension magneto and single non-vibrating coil; self-starter button on dash.
Lubrication of motor by gear-driven force-feed pump from 3-gallon reservoir in crankcase, by internal leads to all bearings. Circulating system with strainer.
Carbureter, Schebler Model L, hot water jacketed.
Gasoline feed by gravity.
Cooling by honeycomb radiator, gear-driven centrifugal pump and belt-driven four-bladed fan.
Clutch, leather-faced cone, with universal-joint alignment.
Transmission selective, amidships, three speeds forward and reverse.
Drive by shaft; two universal joints, double tubular torsion rod encased, and radius rods.
Rear axle, drawn steel type with floating shafts and removable differential; Timken bearings.
Brakes, four, internal and external on rear wheel brake drums.
Front axle, forged, I-beam section, knuckles mounted on Timken bearings; tie rod in rear of axle; reach rod above it.
Steering, by worm and full-circle spur wheel.
Front springs, semi-elliptic, 2¼ by 40 inches.
Rear springs, semi-elliptic, 2¼ by 56 inches, shackled at both ends.
Frame, pressed steel, channel section, narrowed in front, arched over rear axle; motor on subframe; cross members gusseted in one piece.
Wheelbase, 121 inches.
Tires, 36 by 4 inches, front and rear, Diamond or Goodrich.
Rims, Goodyear quick detachable.
Price from $2,500 to $3,850, seven styles.

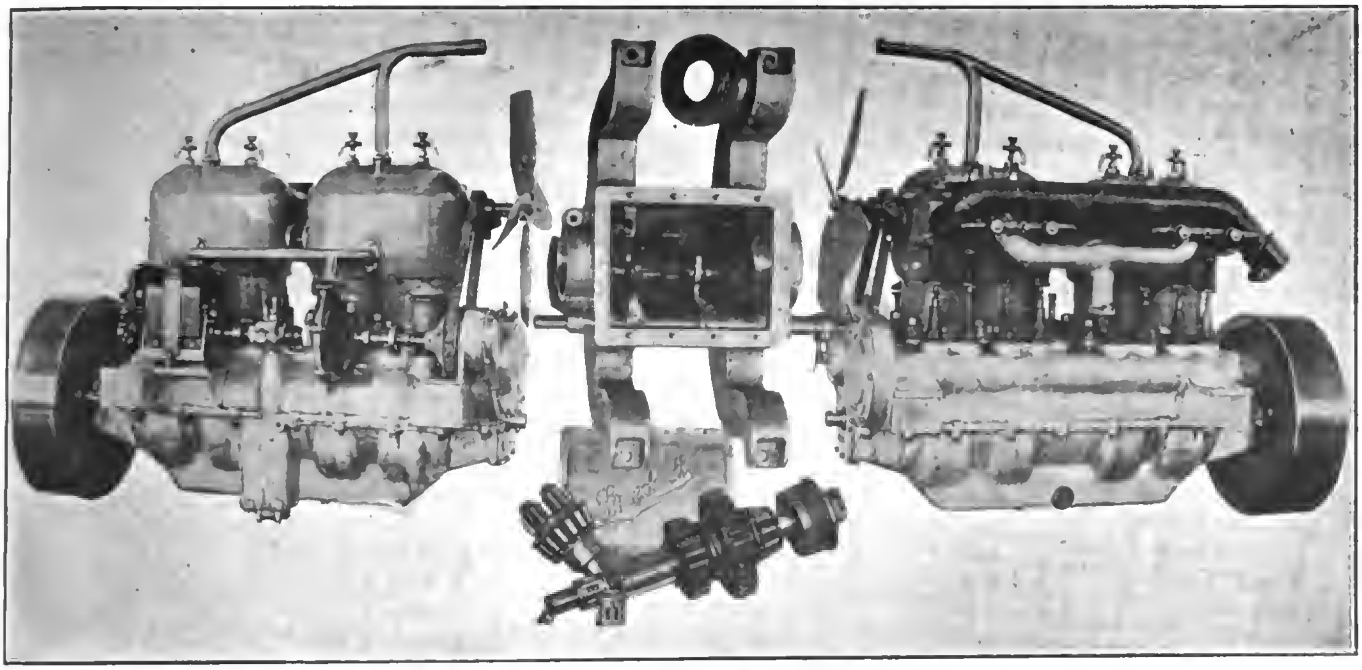
THE keynote of the construction seen in the "Speedwell 50" seems to be an extremely deliberate balancing of all considerations, with a tendency, in case of conflict between mechanical and commercial requirements, to safeguarding the engineer's solution first. The result has been a chassis provided with a robust, 50-horsepower engine, and to which it has been found possible to fit seven different styles of body without violating fitness, congruity and symmetrical appearance. In the seven-passenger touring car and the limousine, the springs are a grade heavier than in the other styles, and the tires are 4 1-2 inches wide instead of 4 inches wide, but otherwise the chassis is unchanged. It has not been possible to accomplish this remarkable result without the greatest care in the choice of materials and construction elements.

The motor is reduced to simplicity in operation and appearance by carefully designing away all superfluous parts. One of its attractive special features is the separate water jacket head for each part of cylinders, this construction assisting much to secure an even thickness of the cylinder walls; and, in case of accidental freezing of the cooling water, the damage is limited to the jacket head. The pistons are cast from reverberatory air furnace iron, the same as used for the cylinders, and are provided with oil grooves to help distributing the splash from the crankcase and four eccentric, lap-jointed expansion rings, three above and one below, are fitted to each piston. The enclosed camshaft, with integral cams, runs in three long phosphor-bronze bearings fitted with oil pockets, and is driven from noiseless bronze and steel gears, helically cut. The intake and exhaust valves are interchangeable.



Chassis of Speedwell Car from Above

The three bearings of the crankshaft are of white bronze, carefully scraped and fitted and proportioned in accordance with the stresses and the weight of the flywheel. The crankshaft, forged from alloy steel and heat treated, is finished in a special crank-grinding machine, insuring a micrometric accuracy which would not be obtained by other means, except at prohibitive cost, and then not with the same degree of certainty.

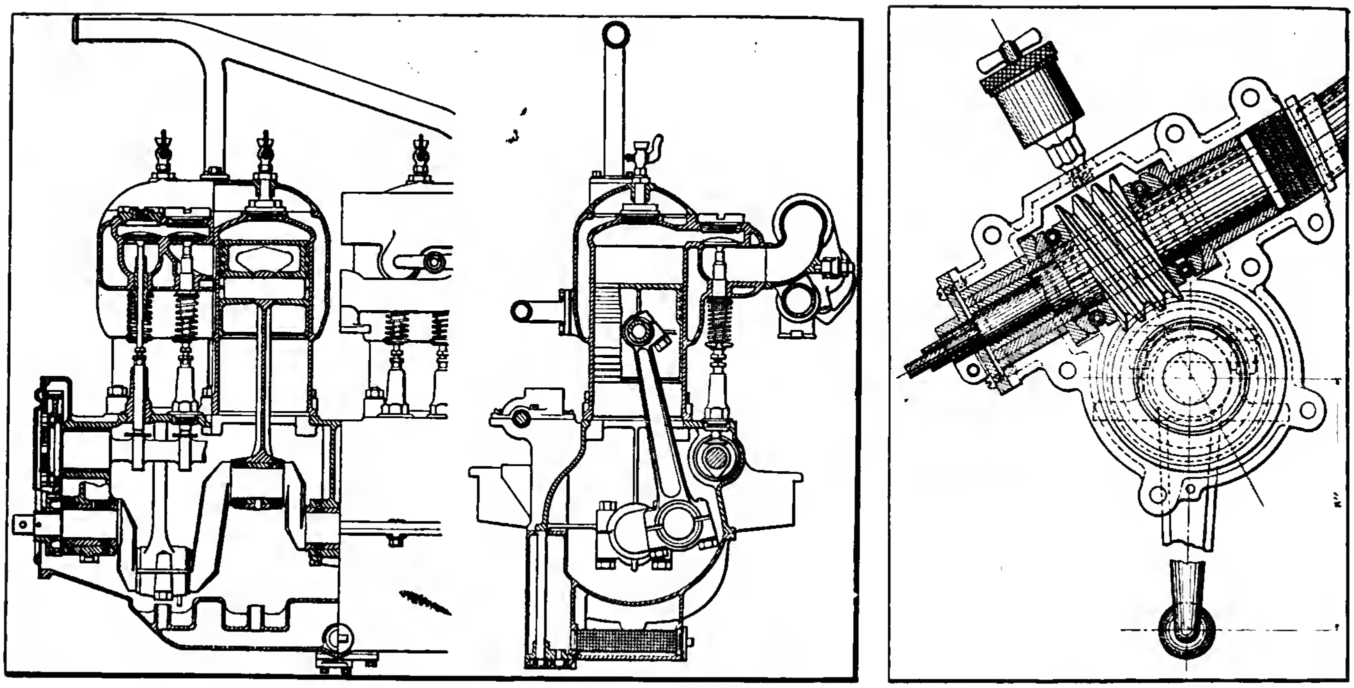


Two Sides of Engine, Showing Auxiliaries. Also, Transmission Showing Transmission Parts

The lubrication system throughout the "Speedwell 50" is very complete and, so far as the motor is concerned, practically automatic. More than forty grease cups are attached to various working parts, including the shackled joints of the springs, each of which is provided with a hardened bushing, and a large force feed grease cup takes care of the steering gear, while the change-gear and differential run in non-fluid oil and the universal joints are packed with consistent grease. Much care is manifested in the placing of the cups where they may be reached with ease. As most plainly shown in the accompanying sectional view of the engine and crank case, the motor is lubricated by a self-contained circulating system, comprising a three-gallon reservoir in the lower half of the crank case, from which the oil is drawn by a gear pump, there located, to a sight gauge on the dash, and thence by gravity or, if need be, by pressure to the bearings in the motor. The piston pin is reached in this way, both from the cylinder walls and by splash. A constant level in the crank case is maintained by an overflow pipe, which takes surplus oil through a metallic strainer back to the reservoir. The height of oil in the latter is read on a gauge conveniently located between the cylinders. The crank case is a sightly casting of nickel-aluminum, in which the crank wells are formed so as to constitute bulkheads, which equalize the amount of oil available for splash at each connecting-rod knuckle, independently of steep gradients of the road.

Cleanliness is taken care of in automobile construction mostly by preventing the lubricants from reaching parts where they don't belong and by reducing the handling of lubricants to a minimum. On the other hand, it is necessary to guard against the insecurity of lubrication which arises when it is attempted to lead oil from a single receptacle through several tubes to a corresponding number of bearings. Any one of the tubes may refuse to work for any trivial cause, while continued feed through the other tubes prevents the fact from being discovered till the dry bearing is scored and gives notice of an injury not easily remedied except by replacement. This matter has evidently been fully considered by the designer of "Speedwell 50." The crank case joint is broadly flanged and the bolts closely spaced, so that no oil will exude. In the change-gear, stuffing boxes on the drive shaft prevent all leakage. Other examples

Large Factory in Dayton, Ohio, Where Speedwell Cars Are Turned Out, Every Part Being Made Here



Sections Through Engine in Two Planes, Showing Details of Construction. At Right, Steering Gear

will appear in the following summary of the other features of the entire chassis, the résumé of the whole being given in the small type at the heading of this article.

The hot-water-jacketed model L Schebler carbureter is provided with three adjustments for low, intermediate and high engine speeds, and these adjustments have been fully verified through road tests of each carburetor at the Speedwell factory. The fuel feed to the carbureter is by gravity from the tank.

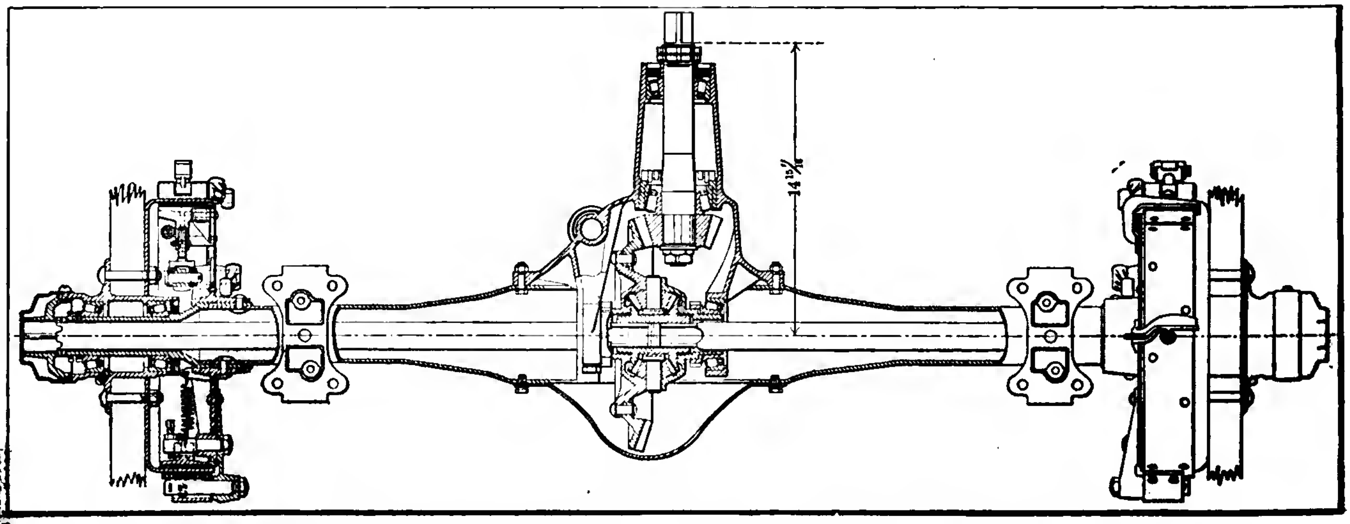
In the matter of ignition, the Bosch dual system has been adopted. The high-tension magneto and a set of dry cells both work on the same set of jump-spark ignition plugs, the dry cells operating through a single non-vibrating coil mounted on the dash in a brass casing fitted with a self-starter button. The circuit-breaker for the dry batteries is mounted on the armature shaft of the magneto, thereby dispensing with the timer.

In the change-gear, which is of the selective type, the driving and driven shafts are both mounted on Timken conical roller bearings, while the telescoping gear rotates on parallel unadjustable rollers. The shafts are of nickel steel and the gears of another alloy, usually designated as vanadium steel. Nickel steel is also used for the propeller shaft, which is forged in one piece with the retainer for the universal-joint cross. Under normal loads, the propeller shaft transmits power in a straight line from the change-gear, which is mounted amidships on a cradle in the subframe, to the bevel gear pinion and differential on the rear axle mechanism, and losses in the transmission of driving energy are further minimized by fitting this drive with two universal joints protected and kept clean by a tight metal casing.

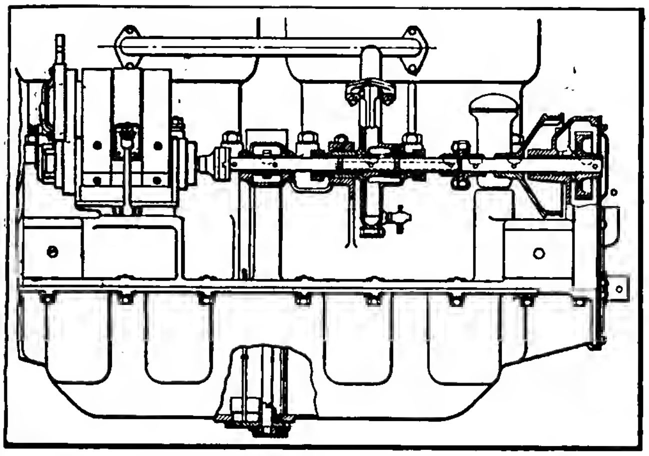
Starts and stops are cushioned by means of a torsion tube hung between oil-tempered springs from the midway cross-member of the frame through the intermediation of a dustproof casing, and the latter is connected with the rear axle by a double torsion tube. Radius rods are also provided to relieve the rear vehicle springs of driving thrusts, so they may be shackled at both ends and have free action, and the radius rods are secured to the frame reaches on each side by ball joints.

The rear axle is of the full-floating pattern, in which the shafts that turn the wheels have nothing else to do, and all weight and road shocks are borne by the tubular housing. Here the pinion shaft, bevel gears and differential run on Timken bearings adjustable for wear, and a large inspection plate permits adjustments and replacements.

The brakes are of the approved external-contracting and internal-expanding type, the service brake being the external one



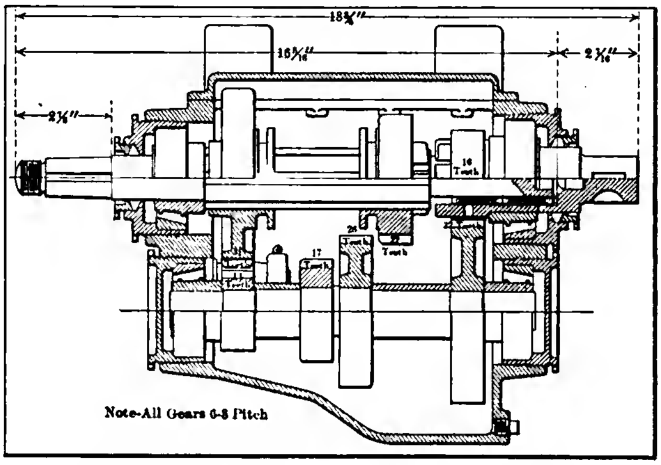
Rear Axle of the Full Floating Type Is Made by Timken, and Taper Roller Bearings Are Used Throughout



Side of Engine, Showing Auxiliary Shaft, Magneto Drive, Etc.

and actuated by pedal, while the emergency brake is operated with a hand lever. This control approaches closely to the generally accepted standard. The brake rods are fitted with equalizers distributing the pull evenly to both brake drums, regardless of small variations in the adjustments of the brake bands, the lining of which the makers guarantee against burning.

The construction of the self-contained cone clutch mechanism is shown very clearly in one of the accompanying illustrations. The end thrust of the clutch engagement is absorbed in a large row of steel balls, and the possible unalignment between motor shaft and transmission shaft, which in former days was the cause of practically all the troubles experienced with leather-faced cone clutches, is neutralized by means of the universal joint shown in the illustration, and the mobility of the joint is secured by keeping it packed in grease. The operation of releasing the clutch at any engine speed is facilitated by a ball-bearing thrust-ring in a dust-tight casing upon which the release-yoke acts.



Transmission Section Showing Liberal Use of Taper Roller Bearings

The cooling apparatus is commensurate with the high power of the engine, the radiator being of true cellular design and the centrifugal pump of large dimensions. This pump, the magneto, the oil pump in the crank case reservoir and the four-bladed fan driven by eccentrically adjustable belt, are all operated from the auxiliary shaft on the right side of the engine.

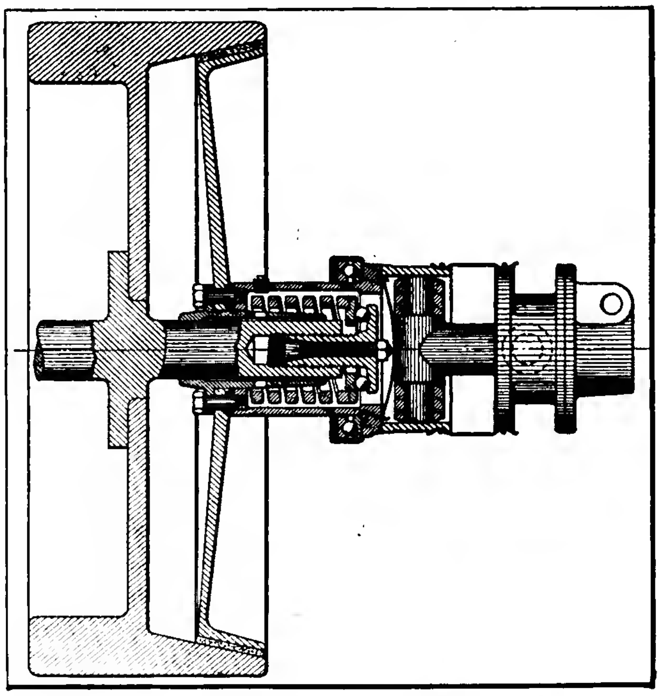
Throttle and timing control are operated in the usual manner through the steering pillar. The steering gear consists of an eighteen-inch wheel of wood on an aluminum web and spider, the tubular steering post, to which is secured a double worm of relatively low pitch, making the action merely irreversible, meshing with a complete spur wheel. The full steering swing involves only 90 degrees of this gear, so that four different portions of the gear will afford the user of the car assurance against loss in his steering mechanism for many years. The provision of a large force-feed grease cup, keeping all rubbing surfaces well lubricated, serves the same end and security against seizing as well. Both the worm and the spur wheel are made from hardened and ground alloy steel. The tie rod is placed behind the rear axle and the reach rod above it, giving the maximum protection against injury from boulders in the road and similar obstructions.

The front axle is an hydraulic forging of I-beam section, toughened by heat treatment and with integral spring seat broadenings of the top flange. The knuckles are mounted on Timken bearings at top and bottom, and the wheels likewise on their rock shafts.

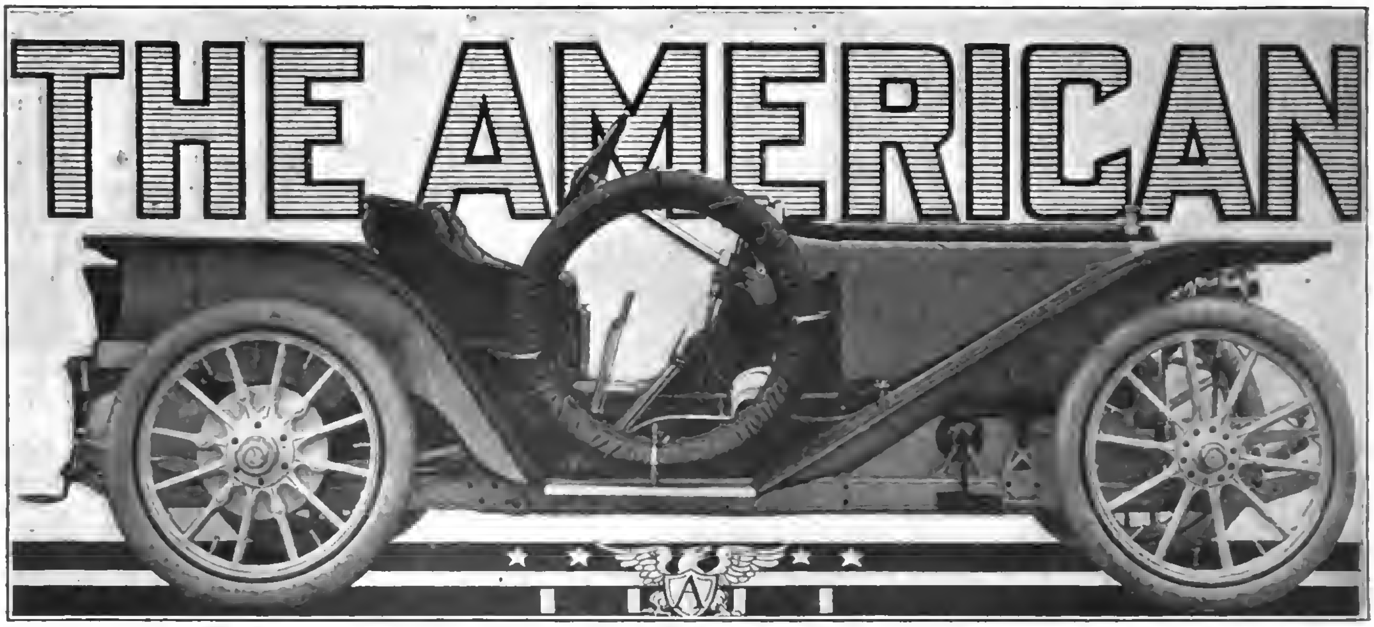
Front and rear springs of the Speedwell are all semi-elliptic and nearly flat, in accordance with modern practice. All eyes are lined with hardened bushings, and all leaves are lipped to maintain their alignment. The front springs are 40 inches long, the rear springs 56, and all are 2¼ inches wide. In the cars fitted with heavy bodies the thickness of each leaf is increased. So as to provide liberal spring action over the rear axle, the frame of the car is here arched, while in front it is narrowed in order to allow sharper turns of the front wheels. It is of channel-section pressed steel with a sunken sub-frame bringing the center of gravity close to the ground in conjunction with ample road clearance. The cross members of the frame are all made with integral gussets, giving a broad and secure attachment to the main frame reaches and reducing the strain on the rivets. The wheel base is 121 inches.

All wheels are of the same size, taking Diamond or Goodrich tires, 36 by 4 inches, with the exception that the heavy body styles, the seven-passenger touring car and the limousine are fitted with tires 4 1-2 inches wide. The body styles produced are the following: A four-passenger toy tonneau, a five-passenger touring car, a roadster or semi-racer for two, three or four occupants; a close-coupled tonneau for five passengers, all these costing $2,500; further, a seven-passenger touring car and a Speedway Special, with a body of striking design, reminding somewhat of the British Lancaster car, these costing each $2,650; finally, the limousine for seven passengers, costing $3,850.

With long wheelbases, wide tread—that is, standard—well designed and large-sized springing, the riding qualities are all that could be expected in a car of this size. The amount of power provided is also ample, either for steep and difficult hills, or for speed work on the level, such as all drivers want to indulge in at times when the spirit moves them.

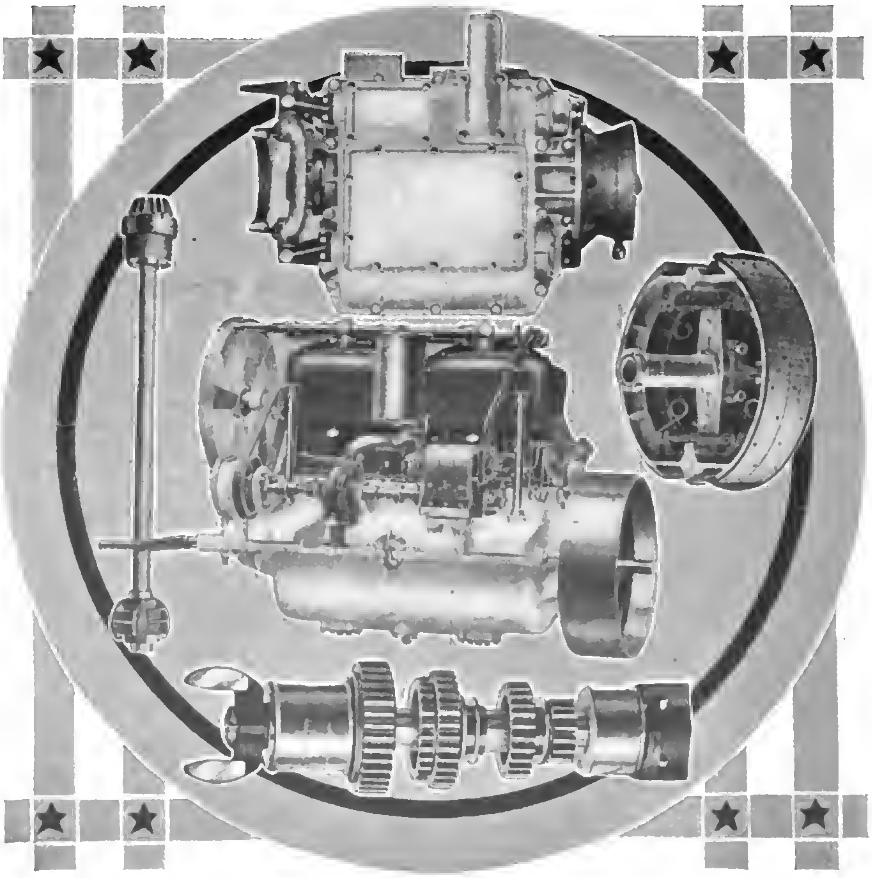


Clutch Is of the Cone Type, With Enclosed Central Spring



American with Traveler Body, the Chassis of Which is Underslung

JUST what importance should be attached to the features in which "The American" differs from all other American automobiles depends largely on the point of view. They produce a highly distinctive appearance and a remarkable steadiness of motion at high speed and turns, and this steadiness, of course, raises the average speed at which the car is operated by its owner and probably also increases his ability to handle the car skillfully at all speeds above forty miles per hour on the road and above sixty miles on the race course. The close hugging of the ground at rapid turns and curves keeps the driver's mind composed, which is the principal requirement for safety in driving at the ordinarily forbidden gaits. But cars habitually driven fast do not last long, unless their design, materials and workmanship help them out. Their tires, too, wear out and tear out quickly by the strains to which high speed exposes them. This is the general rule. But the American, though rather heavy among modern cars, offers the speed without all of its mechanical and financial penalty. The tires last as long as under cars of lighter weight and lesser speed inducements, and the mechanism, generally, "stands up" to its work well enough to keep it in the market year after year at a price competing only with the expensive cars of high renown. These peculiarities seem to be established as more than mere claims and suggest some inquiry and attention with regard to the exclusive feature of design to which they must be due. The underslung frame is the keynote in this design. By hanging the frame on springs secured under the axles instead of above them, the center of gravity is lowered and a change is effected in the direction of stresses arising from stops and starts and from the centrifugal action which tends to upset a car at rapid and sharp turns. The stresses referred to are especially those acting against yielding parts, such as springs and shackles, the frame itself, the tire fastenings and the tires. Owing to the yielding nature of these parts, the weight supported on the frame of an automobile is really shifted forward or backward at starts and stops, and sideways at turns. At a sharp turn the outside tires are loaded more heavily than the inside ones, and the latter are inclined to bound under the reduced load, if the load is lumpy in the least degree. The last-mentioned effect which is disquieting to the driver and wearing on tires is particularly reduced by low suspension of weights, though the strain on tire fastenings may be correspondingly increased.



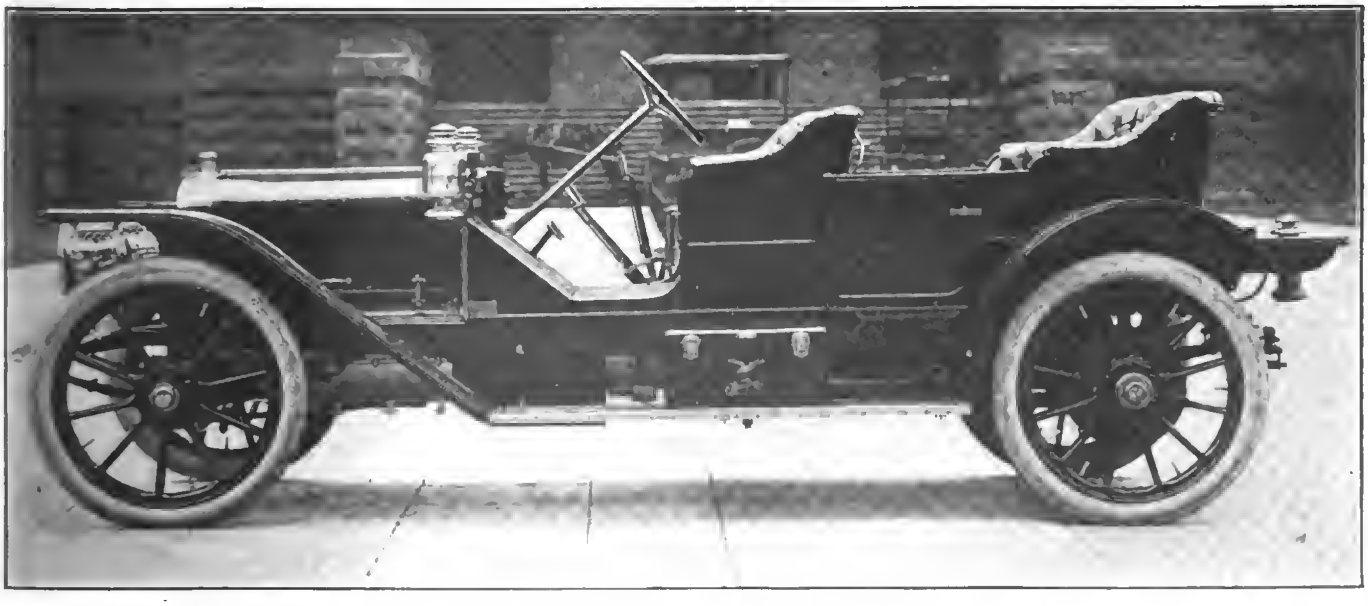
Engine and Transmission Parts, Main Driving Shaft and Expanding Band Clutch

In four out of the six models of the American, manufactured by the American Motor Car Company, of Indianapolis, the advantages of low suspension and low center of gravity are materialized, and by means of large wheels, taking 40 by 4-inch tires in front and rear, the underslung design has been reconciled with a road clearance of 12 1-4 inches in three of these models, and the advantages of wheels and tires of large diameters have been added. In the American Roadster Special the tires are 34 by 4 inches in front and 34 by 4 1-2 inches on the rear wheels, and road clearance is reduced to 9 1-4 inches under the whole length of the car, but the special features of low suspension and stability are accentuated.

Many of the general construction details of the American are shown in the accompanying illustrations, but cannot be described for lack of space. One of the improvements over earlier models consists in the adoption of the F. & S. annular bearings in most places where adjustable three-point bearings were used before. The passage of cooling air through the radiator and all the way through the bonnet is secured by using fan-blade spokes on the cone clutch as well as on the flywheel. Gasoline was formerly fed by pressure taken from the exhaust, but now a compressor pump gear-driven from the camshaft, close to the flywheel, supplies a steady pressure of 1 1-2 pounds from atmospheric air. The pressure can be adjusted to a maximum by adjusting the size of the compression chamber, while any surplus pressure automatically escapes. The universal joint on the propeller shaft is of improved type and the key plates driving the rear wheels are forged in one piece with the floating rear axle shafts. There is noted a convenience in the form of a pipe connecting the tank for lubricating oil with the crankcase, so that oil in the latter may be replenished by simply turning a stopcock. An internal gear pump feeds the oil to the engine bearings, but if splash is desired in addition, it can be had by raising the level of the oil.

In underslinging the chassis, some slight trouble was found in the engine crankcase shape and placing. This was easily remedied by placing the arms of the crankcase very low, and bringing the supports up very high to meet them, the latter being set well above the main frame of pressed steel, and being themselves of pressed steel. Even this placing of the power plant did not introduce any uncertainty of accessibility, for the arms divide right at the parting of the crankcase, so that the lower half is entirely below the subframe, and thus removable from below without disturbing the latter. So, it is, that despite the underslinging and very low center of gravity, the engine bearings are as accessible as any overslung car of the modern type. From the appended illustrations of various parts of the car selected at random, it may be noted that the whole design shows nothing of the freak, being designed—aside from the underslinging—strictly along conservative and approved lines, and following what few accepted standards there are in existence in the automobile business to-day.

End View of Engine, Steering Gear, Rear Axle, and Transmission Parts

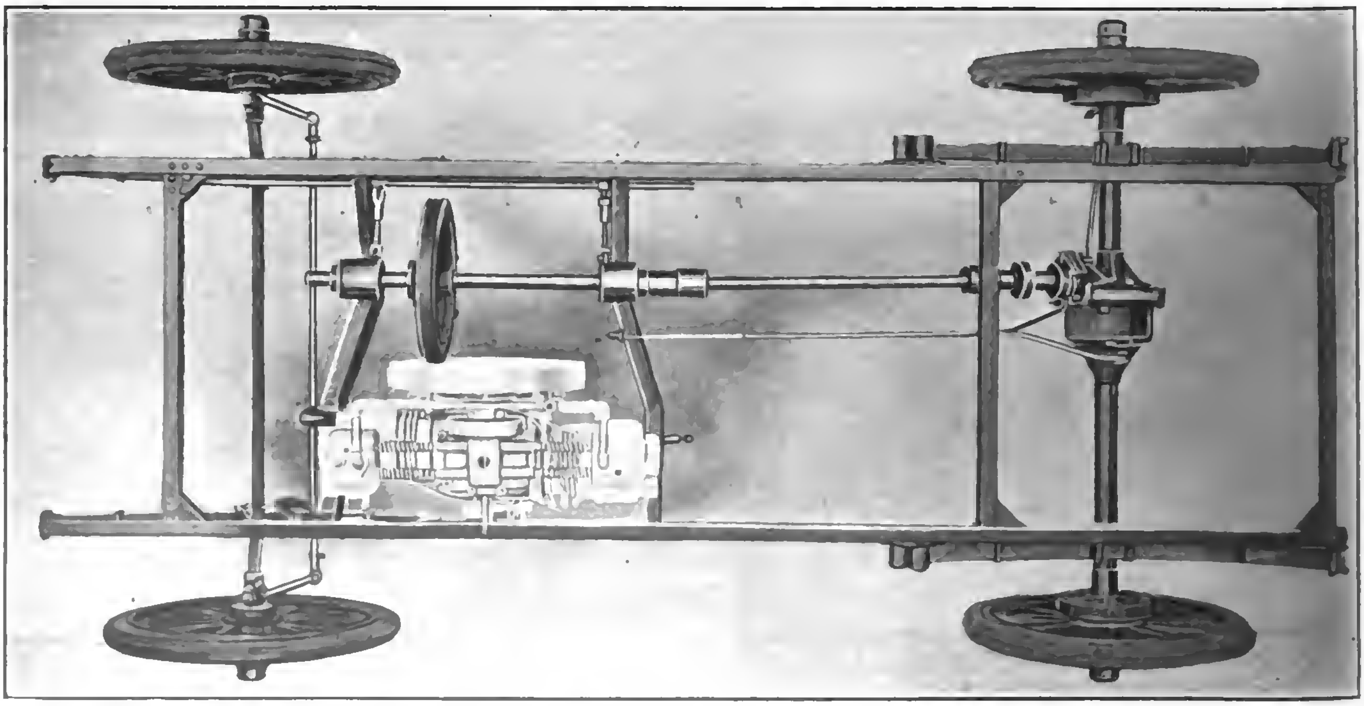


Touring Body on the Regular Model, Known as The Tourist, 50 Horsepower.

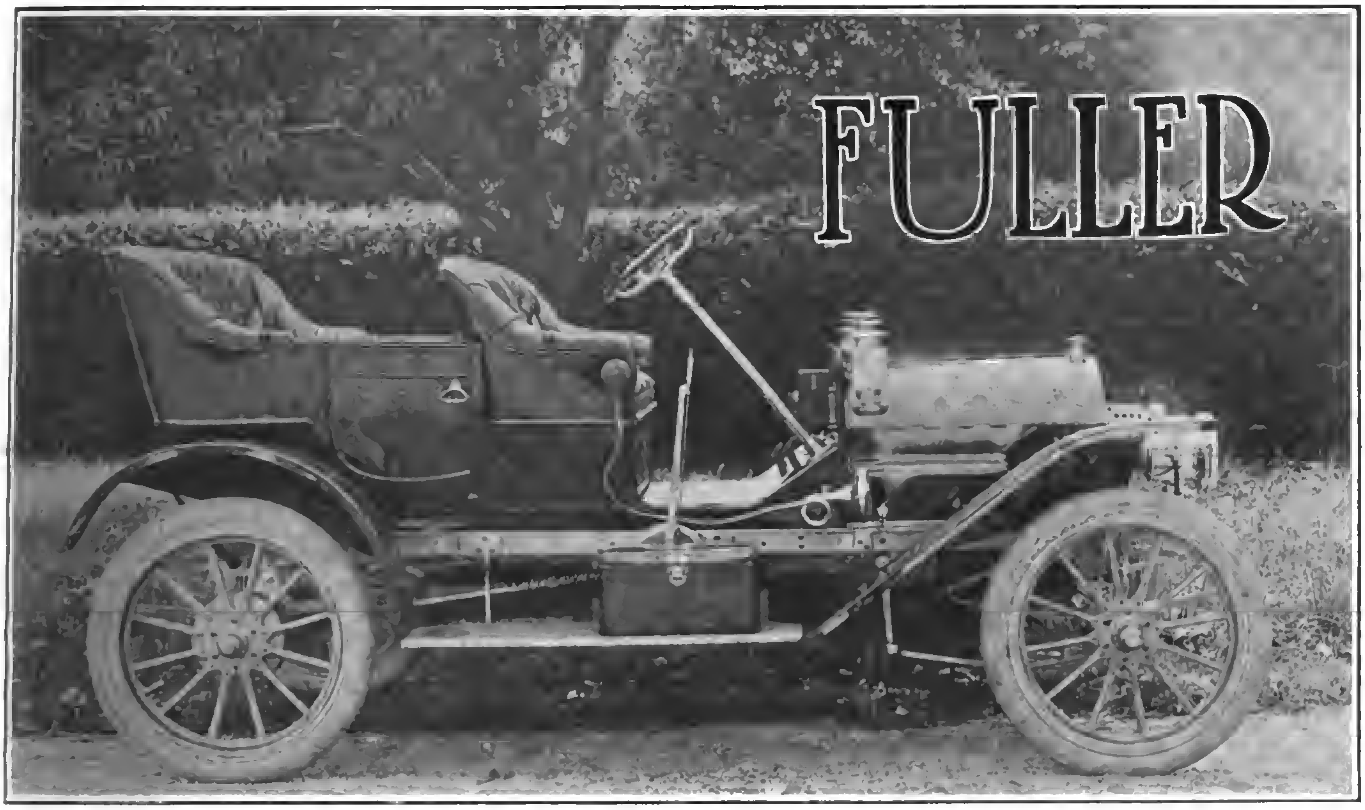
Delivery Wagon as Made by the Van Dyke Motor Company, of Detroit, Mich., a Newcomer

UTMOST simplicity of construction and the price of $750 for a complete delivery wagon, self-propelled, form the basis of comprehensive plans with which the Van Dyke Motor Car Company is entering the automobile industry, with temporary offices at 1221 Ford Building, Detroit, Mich.

The design, whose general features are sufficiently indicated in one of the accompanying illustrations, is due to the ingenuity of George P. Davis, of Detroit, and shows a well-defined purpose to take advantage of the advanced reliability of motors and parts for eliminating every element of construction which would add to the cost and trouble of upkeep and which may yet be superfluous for the successful transportation of light and bulky merchandise. George A. Trout, as general sales and factory manager, is to take care of those qualities of materials which will safeguard the results. Plans are under way for a factory with space for assembling, body-building and painting.



Chassis of Van Dyke Delivery Wagon, Showing the Two-Cylinder Opposed Engine and Friction Drive



Touring Car as Made by the Fuller Buggy Company, Jackson, Mich., a Newcomer, Has Pleasing Lines

IN the recent models of cars made by the Fuller Buggy Company, of Jackson, Mich., a number of changes are made as compared with the design shown in the accompanying illustrations, and all of them are in the direction of improved style in details and the correction of those minor imperfections which are inseparable from all beginnings. Among the leading features which remain unchanged, are the following: In the $1,500 model, the four-cylinder motor is 4-in. bore by 4 in. stroke, developing a little more than 25 horsepower, tubular radiator, planetary transmission armored wood frame, five plain bearings for the crankshaft, roller bearing axles, weight 1,900 pounds, tires 32 by 3½-in. front and rear. In the $2,000 model, the four-cylinder motor, 4½ by 5, developing 32 horsepower, the cellular radiator and a total weight of 2,100 pounds, constitute the principal distinguishing construction features, aside from the differences in style. Both types have double ignition, by magneto and dry battery, multiple disc clutch, lubrication by gear pump and two speeds and reverse by the planetary transmission. The drive is by shaft to the semi-floating rear axle, and the springs are full-elliptic in front and rear, protected by substantial radius strut rods from the rear axle to the frame reaches. A roadster type, Model 30, with rumble seat, has been added to the output of the firm. The development of the Fuller Buggy Company's production of automobiles has been so rapid, in response to the demands of the market, that great ability has been required in the mechanical department for keeping pace.

A Car with High Wheels and Solid Tires for the Country Folks Is Also Made by the Fuller Company

IN THE SOLUTION OF SOME RADIATOR PROBLEMS

FROM the radiators as used in the earlier makes of automobiles down to the types as they obtain at the present time, represent a long series of attempts to bring about the highest obtainable efficiency and great life of the radiators in service. Efficiency and life seem to oppose each other, it being the case that the methods by which efficiency is increased are those which are likely to produce a mechanically weak structure.

The power which may be taken from a given motor depends upon the fuel which is burned to carbonic acid and water in the process, but since the thermal efficiency of a motor is probably under 20 per cent. in the best types, and an average of perhaps 16 per cent. in good motors, it will be appreciated that as the power of the motor is increased the quantity of heat which must be absorbed by the water in the cooling system increases enormously. The only possible way that the power of a motor can be increased without seriously affecting the proportions of the radiator is that which involves an increase in the thermal efficiency. It took a great many years to bring the thermal efficiency of steam engines from say 5 per cent. at the start to 16 or 17 per cent. as they obtain in the best types at the present time. There is small chance of this type of engine being increased in point of thermal efficiency to any great extent. The internal combustion type of motor made a somewhat better thermal showing from the start, and it is reasonable to suppose that the thermal efficiency in the crude types of internal combustion motors approximated 10 per cent.

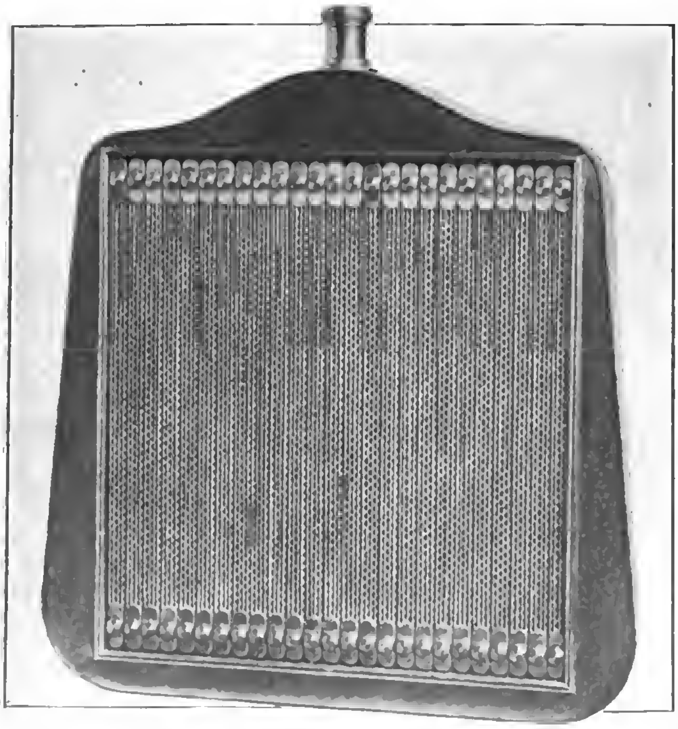


Fig. 1—Appearance of the finished radiator, ready for use, showing that it has an excellent appearance

During the last ten years the thermal efficiency of internal combustion motors due to their better construction as developed in automobile practice was increased from the low figure above given to approximately 20 per cent. in the very best types of the present time. This change had the effect of reducing the cooler requirement to one-half of that which obtained in the primitive automobile applications, but it still leaves an enormous amount of heat which must be taken care of either by the radiator or by way of the exhaust.

Attempts have been made from time to time to reduce the amount of heat which would have to be absorbed by the exhaust, which efforts involved the use of large valves, and a timing of them such as would give to the exhaust the widest possible opportunity to escape. It is possible that in some of these motors the heat which must be absorbed by the radiator falls to a point considerably below 50 per cent. of all the heat represented in the fuel used.

In everyday practice, considering the problem as a whole, the cooling situation is complicated by the fact that flexibility is desired, and it is further influenced in view of the practice of the average autoist who persists in slowing the motor down by the process which involves the retarding of the spark. It is on account of this cooling problem that most taxicabs, for illustration, are so designed that the spark is fixed but the average efficiency with a fixed spark, while it will not be the maximum obtainable, will be better than that which can be realized if the chauffeur lacks ability to reason, and drives his car on a basis of cause and effect. The chauffeur soon learns that the motor will lose power when the spark is retarded, and the car will slow down in consequence; if his knowledge does not grow beyond this point, it will take a very extraordinary radiator to absorb the heat which will be given off by the motor, without causing the water to steam.

An overheated motor is incapable of delivering its maximum power, and if the condition of overheating passes beyond a certain point, the amount of power may reduce excessively. The pumping losses in a motor increase enormously with increases in temperature beyond a certain point, which losses may be subdivided in the manner as follows:

(A) The increase in temperature rarefies the incoming mixture, and the weight thereof will be decreased accordingly, so that the possible power of the motor will be lowered in consequence.

(B) The higher range of temperature will introduce lubricating trouble, and the friction loss will be enormously increased.

(C) If the condition of heating passes beyond a certain point, the piston clearance will reduce because the piston will swell faster than the bore of the cylinder will increase, and this con-

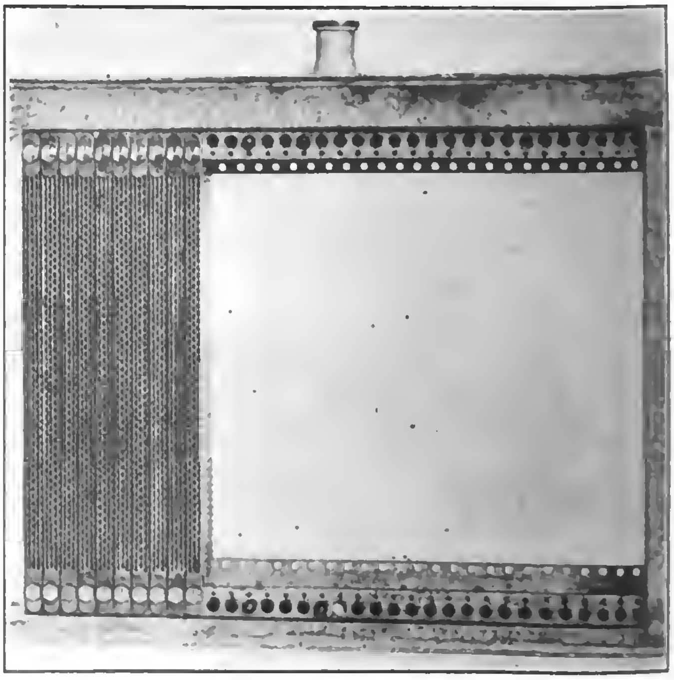

Fig. 2—Truck radiators are made like those for touring cars, the difference being in the size and shape

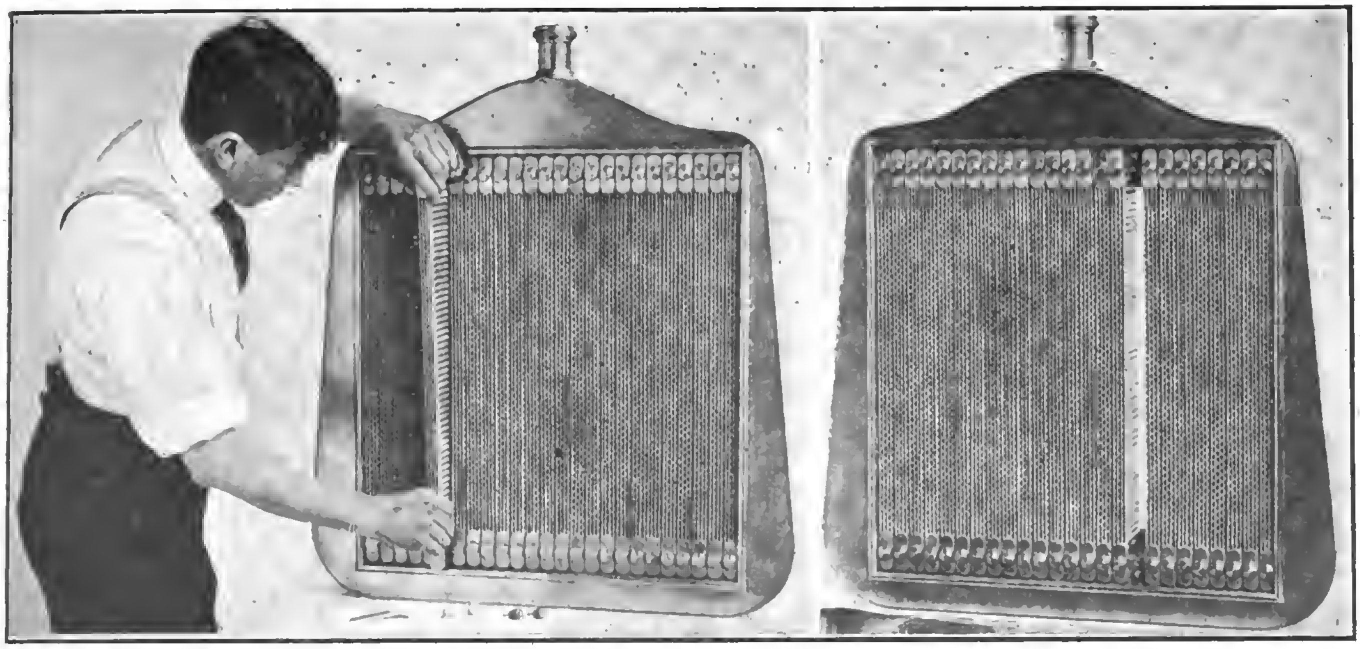

Fig. 3—Method of removing individual sections of the new radiator. At the right, appearance when a section is removed

dition may extend to a point of sticking of the piston.

(D) It is highly improbable that expansion due to heat will take place uniformly in all radial planes, and piston distortions will scarcely conform to cylinder distortions due to heat, so that there will be zones of excess pressure which will increase the pumping losses.

With these increases in pumping losses, the remaining sources of the same character of losses will be more or less influenced, and it is scarcely to be supposed that any motor will satisfactorily perform excepting when the temperature is properly regulated, and this condition will only obtain if the cooling system is maintained in good working order, provided it is properly designed in the first place.

Passing beyond the motor, the remaining important questions are tied up in the radiator and its construction, together with the means of water circulation. Considering a given motor, the size of the radiator will depend upon the rate of circulation of the water to a considerable extent, although it has been determined that the advantages derived by circulation cease after a certain point is reached. If the ratio of radiator surface to flame-swept surface in the cylinders is properly regulated, the circulation may be that ordinarily called thermo-syphon (natural circulation). Obviously, this character of circulation is relatively sluggish, and the ratio of cooler surface to flame-swept surface in cylinders must be adjusted accordingly.

If a pump is used, the size of the same may be anything, and the rate of water circulation may then be increased to any desired point, but, as before stated, it has been found that it does no particular good to increase the rate of water circulation beyond a certain point. As a practical figure, it may be said that 1 1-3 pounds of water per horsepower per minute will suffice for the average automobile if the radiator is well designed.

There is one point in this connection which does not usually receive consideration: if the amount of water present in the system is much restricted, steaming will transpire, due to the fact that the steam which is formed over the hot surfaces of the combustion chamber will not be afforded sufficient time and water in which to be condensed. Condensing takes time, and that steam does form over the dome of the motor cylinders has been shown. In designing a cooler, then, it is necessary to consider not only the surface exposed to the air draft, but the quantity of water which will be necessary as well.

In practice there is a further and disconcerting factor due to the deposit of foreign substances out of the cooling water, which deposit forms a coating over the wetted surfaces in the cooler, and this coating being almost a non-conductor of heat reduces the efficiency of the cooler enormously. The factor of inefficiency due to incrustation increases as the square of the thickness of the coat formed.

The idea of being able to demount the radiator seems to be a good one, since then the several sections may be treated separately, and by means of direct pressure it will be possible to eliminate the incrustation, and, as a further advantage, it will be possible to repair leaks which may develop in one or more of the sections. One of the important considerations is involved in the ability to remove a section with the car on the road and to plug up the openings, thus rendering the radiator sufficiently capable to serve for the purpose, even when one or more of the sections are disabled. This idea is here illustrated in which Fig. 1 shows the radiator complete, with means at the top and bottom of the sections by means of which they may be removed at will and through which they are held in tight relation at all other times. This type of cooler was developed by Rehringer Radiator Works, 83 Fulton street, New York City. Fig. 2 shows a form of this cooler designed for commercial car work, with all but 10 of the radiator sections removed, thus giving an excellent idea of the method in vogue. Referring to Fig. 3, the same cooler as illustrated in Fig. 1 is shown at the right with a section removed, and at the left with the process of replacement of a section under way.

The sections of this form of radiator are made up of flat copper plates corrugated to give strength and to increase service. Three of these ribbon-like water tubes go to make a section, and the means of holding the sections into place constitute a dowel pin at the top and bottom to the rear of the sections engaging a back plate. Water passes from the frame proper through the die formed, engaging terminals as shown in rows across the top and bottom of the cooler, and a tube inserts with a packing ring in concentric relation, so that the joints are made tight when the holding screws are pressed home. It is claimed for this new design of radiator that it has precisely the same radiating surface, volume of water, and other desirable conditions as will be found in the better types of radiators in general, and the scheme of design is such as to permit of the removal of any section at will, either for the purpose of repair or for the removal of incrustation. Every facility is offered for the quick removal of any one or all of the sections, and the means of packing at hand are such that tightness is bound to follow if the holding screws are pressed home, which is a mere matter of the vigorous use of a screwdriver in the absence of any great skill.

Aeronautic Progress Along Constructive Lines

By MARIUS C. KRARUP

LAST week a number of theses closely related to the construction of aviation machines were presented. Some of them were in agreement with accepted aeroplane theory and practice, but others were at variance. This rapid, introductory presentation of theories or statements all of which are not above debate, is continued in the following. The most unorthodox among them are capable of defense in the present state of technical knowledge of the subject. If some of them should provoke observing readers to the expression of contrary opinion, there would be gained an acceptable basis for a more thorough discussion, from which in the end a stock of real data on aeronautic engineering may be laid by. The many shortcomings still attaching to aviation machines make it a foregone conclusion that no set of theories which would at present seem acceptable to all, even the best informed, can have any chance of being found correct or complete later, in the light of the developments and improvements which are to come.

If the balancing and safety of aeroplanes were to depend on a watchful control action, necessarily following rather than forestalling the disturbing influence—since the latter always takes the form of invisible air currents or eddies—the chances for aviation becoming a practical form of transportation would be removed to a dim future, but the introduction of flexible elements in the planes will place this matter of safety on a new footing. As it has been shown that an aeroplane can be jolted out of balance by gusts, it is just as certain that it will require a flexible and resilient suspension, as that an automobile requires springs. But the reasons are more numerous and urgent, because the aeroplane "springs" will not only smooth the road and preserve the balance but will also harden the road; that is, make the planes more efficient as supporters of weight. The theories and mechanics on this point are intricate but interesting.

With the aeroplane machine a rigid construction, as it is today, any control device which shall give hope of enabling the aviator to right the structure after its equilibrium has been disturbed, must be extremely quick in action. The loss of equilibrium places gravitation in charge of the machine for the moment. Consequently, the control device must be actuated by something much quicker than gravitation, such as is brought into play by shifting of weights. Muscular activity is such a quick-acting force only if the recoil from the push or pull does not counteract the intended control movement by shifting the weight of the operator's body in the wrong direction. It is best to spend the reaction from a muscular control effort as a strain to separate two rigidly connected portions of the structure. In some machines these reactions from control movements are very properly spent in a strain reaching from the footrest through the aviator's body to the back of the seat.

But all control is still a makeshift. Quick action is sought in placing the control planes a considerable distance fore and aft of the main plane or planes, so as to give them long leverage, but the same provision also gives a gust of wind acting upon the control planes a long leverage to upset the machine.

It is doubtful if the balance of an aeroplane, once lost, has ever been regained by means of the control apparatus. The latter consists only of rudders, and the action of rudders depends on speed, and this speed must, moreover, be very nearly in the direction of the rudder's normal extension. If the upsetting force jolts the machine more than twenty degrees away from its normal poise in the atmosphere, while its momentum perhaps still carries it on in its previous direction, or if the jolt in any way stops its progress, the present control apparatus is useless. Automatic stability, probably by means of flexible and resilient elements in the planes and reinforced by a low center of gravity—though the latter is wholly superfluous during normal flight—is therefore absolutely predestined to engage attention.

The relative merits of biplane and monoplane are most clearly shown in the fact that nobody has succeeded in building a flying monoplane so large or so heavy as biplanes are frequently made, although materials and workmanship have so far been more select in monoplanes. To get both surface and strength in the monoplane it has been necessary to broaden the plane, fore and aft, and this produces irregular shifting of the centers of pressure or support, as planes are made at present.

To hold these broad planes to a regular tilt, despite their naturally fitful action, it has been necessary to provide long tails and to have these tails so heavy as not to be self-supporting in flight. This provision, again, has reduced the advantage which the monoplane would otherwise intrinsically have over the biplane by virtue of smaller air resistance per square foot, by compelling the monoplane to be operated at higher tilts. Probably the higher tilts are responsible for the impression that a monoplane can support more weight per square foot than the biplane.

On the other hand, if the tails are made nearly self-supporting by means of attached surfaces, they become a source of danger in blustering weather. If too heavy, they are dangerous if the motor is stalled. But all these relations between monoplane and biplane are subject to change the moment the stabilizing tail becomes superfluous; that is, when means are found for equalizing pressures under broad planes or planes placed tandem.

The principal requirement in this respect must be to break up the irregular eddies which are known to form under broad planes, or, rather, to cause them to be formed as a large number of small and well-distributed eddies of resistant air, instead of as unruly little tornadoes shifting from one point under the plane to another. And it seems instructive to note that irregularity is most pronounced under flat planes and under broad planes, while curved planes and narrow planes are more manageable. A strongly curved plane may be made broader than is advisable for a plane approximately flat. This has been abundantly demonstrated to hold good for present conditions, and furnishes a clue for the inventive faculty.

In the writer's opinion—and doubtless the same idea works under shroud of silence in many other minds—planes will eventually be made to consist of a rigid front portion, comprising about one-third of the plane's width, and a larger, more or less elastic rear portion, capable of yielding to excessive local pressures and causing the center of support to be maintained steadily under the rigid front portion, and that about one-half of the area of the planes will be covered with small, shallow air pockets, which will take the place of pronounced curving of the whole plane, without involving nearly so much air resistance against propulsion. A development of this description, while not plainly foreshadowed in the facts so far ascertained in connection with the flight of aeroplanes, is consistent with all these facts, inasmuch as none of them excludes it.

The monoplane when no longer requiring to be ballasted by means of a tail to prevent it from pitching, will be the natural small-size and light-weight flier. It may readily be made compact for storage, and fast, but no reasons have ever been offered for abandoning the belief that the biplane will always be the better carrier of weights. Bridge construction presents a parallel which few engineers would consider short of conclusive in this respect.

While on the point of probable improvements in the fundamental characteristics of planes, whether for monoplane or biplane machines, it seems necessary to call upon the soaring bird to furnish contributory evidence to the effect that some one law closely related to aeroplane action still remains unrevealed and unapplied. On the basis of accepted theories, only a rising air current can explain soaring, and the explanation is very lame at that, weights and speeds of birds and air currents all considered. But then comes, moreover, the fact that small birds cannot soar; that is, not without previously gained momentum. And, in small birds, the wing and tail area is larger in proportion to their weight than in large birds. Soaring should be easier for a small bird, such as the swallow, than for the buzzard or the stork, if the accepted explanation were complete. On the other hand, if the explanation is insufficient, fundamental improvements in planes, imparting to them something akin to capacity for soaring, must be possible, and must eventually be developed.

Most analogies between birds and aeroplanes are unscientific, as when the shape of a bird's wing is imitated in the planes. The lack of essential similarity in methods of flight and properties of materials vitiate the comparison. The dihedral angle, as in Latham's monoplane, is praised as safe on the ground that many birds sail with their wings held V-like. Dissection, however, lays bare, in some birds, a bony projection which offers a simple mechanical explanation of the V-shape as one which can be maintained without muscular effort.

The concentration of weight at the middle of an aeroplane seems to be an unconscious imitation of bird construction, since it is evident that the biplane truss, resting on air with its entire length, would be stronger, or could be built lighter, if weights were more evenly distributed, and that it would also be more steadily balanced in the atmosphere, as a gust of wind, attacking one end of the structure, would not find so long a lever for upsetting the machine.

The required strength of the machine, when resting or propelled on the ground, rationally calls for a construction balancing the weighty parts over the skids or carriage foundation. By broadening this base, the engine, fuel supply, passenger load and propellers could be disposed of, as now done only in Wright biplanes to some extent, so as to increase the strength or reduce the weight of the structure considerably, though the builder would also have to consider the uniform distribution of air resistances.

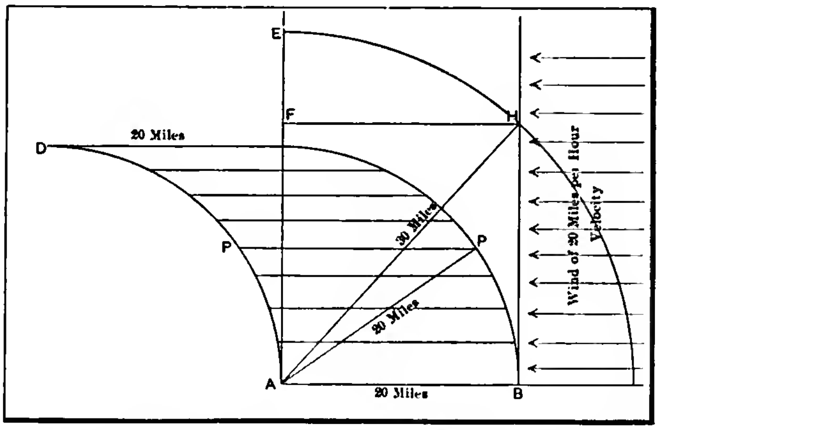
Fluttering or an apparently unstable or imperfect equilibrium during flight may be due to the use of flat ailerons for steering purposes, to lack of rigidity in the front edge of planes, to flat and rigid lift rudders, to lift rudders placed too low and out of line with the propulsion, to baggy planes, to operating flat planes at tilts above 15 degrees. Only under abnormally severe atmospheric conditions may it be due to a high center of gravity.

The Dirigible Balloon Without Gas

Every improvement of aviation machines which cleave the atmosphere alike to the bird, reduces the ultimate value of dirgible balloons, as the common-sense mind has already easily perceived without technical demonstration, but for the present the buoyancy of the dirigible still lends it certain advantages of safety under difficult weather conditions and possibly some superiority for reaching very high altitudes. These have endeared it to the military authorities, and its capacity for carrying considerable loads or a number of persons with much more body comfort than the aeroplane affords, has been so prettily developed in the Zeppelin type as to keep the question of the further perfecting and utility of dirigibles alive and open.

By arranging the great bulk of his buoyancy chamber in highly elongated form and adopting mammoth dimensions as the only means for attaining a rigid construction in combination with a low specific gravity, Count Zeppelin seems to have almost exhausted the possibilities of the dirigible balloon as a traveling machine, and by compartment division of his gas reservoir—much facilitated by its rigidity—safety has been much increased. It is hardly consistent for constructors of aviation machines to pooh-pooh the competition of the Zeppelin type of air craft, on the ground that it will never be able to navigate with any considerable degree of independence of currents in the atmosphere in which it is suspended and of which it forms a part by its bulk and buoyancy. It is easily demonstrated by a diagram that a Zeppelin machine capable of just holding its own against a headwind blowing twenty miles per hour cannot do any better against a sidewind of the same velocity, contrary to common opinion which credits it with a capacity for tacking up against unfavorable air currents. As the diagram shows, this capacity only begins when the speed of the machine is superior to the velocity of the wind. But a salmon, for example, that braves the currents of the Columbia River and even jumps against cataracts, affords a striking demonstration of ability to navigate though completely suspended in a medium of the same specific gravity as the operating machine. The questions involved are only those of power and strength of construction. The salmon has these properties in relation to water, and the dirigible balloon may acquire them in relation to air. If Zeppelin's propellers were twice as efficient as they are, his machine's ability to navigate against air currents would be immensely multiplied, provided the envelope of his reservoir would be able to withstand the much increased pressures to which it would be subject.

The engineering possibilities of the dirigible are, consequently, still attractive, and new ideas in this connection are not to be ignored. One of these relates to the use of a partial or nearly complete vacuum to take the place of gas. This budding idea is strictly a development from Zepperlin's success in attaining rigid construction without excessive weight. It is reasoned that it should be no more difficult to make the panetela-shaped reservoir strong and tight against an evenly distributed crush from the atmosphere—with diminishing pressure in the upper strata as an important incidental advantage—than to give it the properties required for holding hydrogen and at the same time rigidity against wind pressures. The vacuum would remove the danger of conflagration now due to the proximity of a hot engine, hot exhaust and possible gas leaks, and, most important of all, the buoyancy could be produced or enhanced by the engine power in any place, independently of such special facilities as are required for filling a balloon with illuminating or hydrogen gas. A semi-vacuum would be about equal to illuminating gas as a buoyant and would involve a pressure of only 7½ pounds per square inch. Leaks would be less liable to occur with pressures converging to the axis of the construction than in the gas balloon in which the pressures radiate from the axis and tend to expand materials. And a construction capable of withstanding 7½ to 15 pounds of pressure from without could probably be conveniently kept tight by repair work carried on while the structure is in the air, and any desired degree of vacuum, even varying according to the altitude, if desired, could be maintained by connecting exhaust pumps with the engines. From another source it is suggested that some of the methods employed for producing liquid air would be found of advantage for exhausting air from the reservoir.



Action of dirigible in side wind, of 20 miles per hour. Maximum speed supposed to be 20 miles per hour, and machine headed for any point as P in curve B C, but after one hour of travel it can do no better than reaching the corresponding point as P in curve A D. But when the speed of the dirigible is increased to 30 miles per hour, it can be headed for point H, and will land at F, after one hour; and F is in the desired direction of travel.

Adjusting the Carbureter—for the Novice

By HERBERT L. TOWLE

ADJUSTMENTS are many and various, hence it was an impossibility to close the subject out last week, in fact, it was cut off somewhat abruptly in the midst of a discussion of springs, spring winding and spring tensions. This subject is of vital interest, for not only does the amateur want to know about it for repair purposes, but a full knowledge of it will avail for correcting defects in springs sent out by the makers, as well as helping very materially in case of trouble, in that it allows one to make a better and more rapid diagnosis of the trouble.

In winding a new spring with more turns, it is best to start with too many and shorten the spring by degrees till it is right.

In the foregoing it has been assumed that the float has been correctly adjnsted. It is wise, however, to satisfy one's self on this point before altering the spring. A slight drop or bead of gasoline on the spray orifice is permissible when the car is at rest on a level floor. If the level is too low, extra suction will be needed to lift the gasoline. If, however, it is too high, the gasoline will drip. Changes in the float valve adjnstment must be very carefully made, as it is very easy to over do them, particularly when the float has a long leverage on the valve. Instead of adjnsting the needle valve to raise the gasoline level, one may add weights to the float. If the float is hollow copper or brass, it is easy to add a drop or two of solder. If the float is cork, a bit of lead or brass may be screwed to it and shellacked over to prevent gasoline from soaking into the cork. If the float is of snch form that a single weight will cramp its action throngh lack of balance, two or more weights equally spaced around it should be nsed.

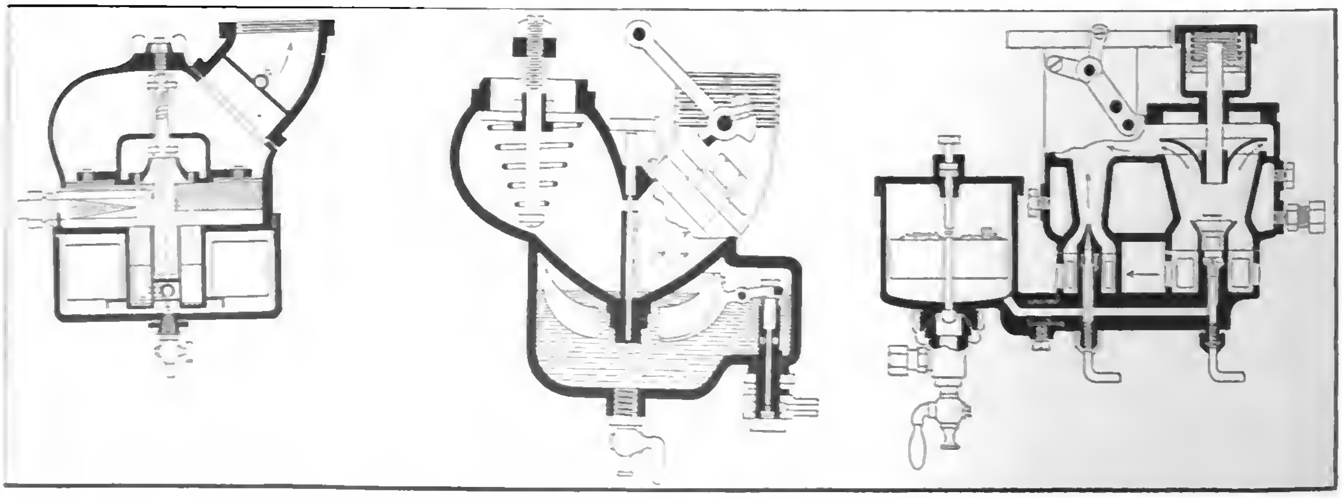
Many carbureters have the float annular and surrounding the spray chamber. The object of this is to prevent tilting of the carbureter on changing the gasoline level at the nozzle. Where the float chamber is offset from the spray chamber it is preferable to have the float chamber forward of the spray chamber, so that the gasoline level in the latter will be higher when going np hill. This will automatically increase the gasoline supply on grades when it is most likely to be needed and reduce it down hill.

To avoid the complexities of the automatic air valve, some carbureters are made with the diluting air inlet connected directly to the throttle, so that opening the throttle opens the pure air inlet. With this arrangement the pure air is not admitted till the throttle has begnn to open, so that with a low throttle opening all the air comes past the spray nozzle. Fig. 1 is an example of this type. The throttle serves a double function, nncovering the pure air inlet at one end. The air thus admitted goes through the body of the throttle, which is annular in shape, and mingles with the carbureted stream at the throttle opening. The difficulty with this type of carbureter is that it does not take account of the varying degrees of suction possible to an automobile without change of throttle opening. For example, one prefers the throttle wide open when going up hill, but to open it wide in the carbureter just mentioned would be to dilute the mixture excessively. Again, when running down a slight grade with the throttle barely open, the mixture would be too rich.

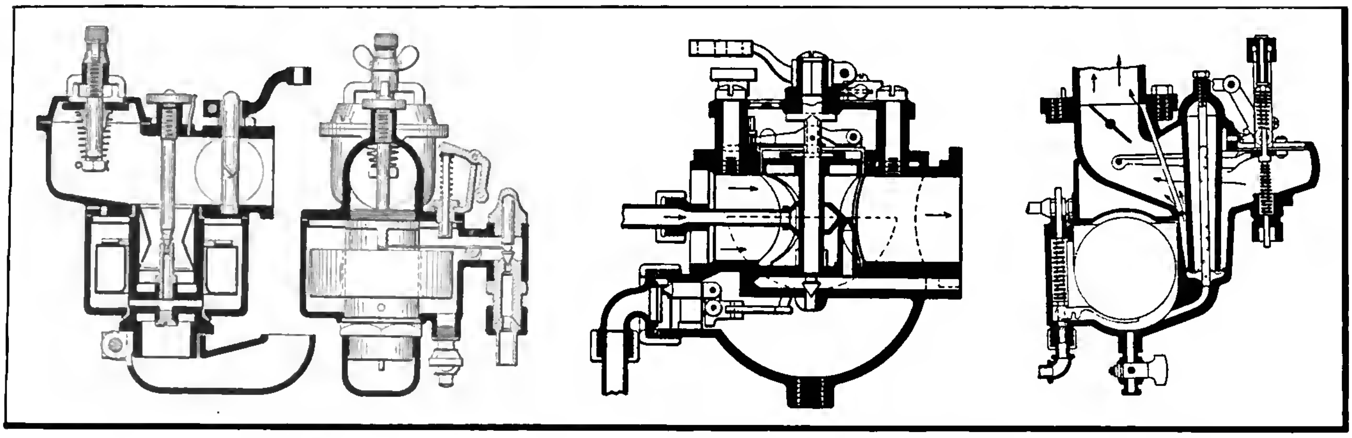
What is known as the puddle type of carbureter has been offered in the last two years, as an escape from the complexities of the air valve carbureters with three or four adjustments. In this carbureter the float is annular, and the mixing chamber is U-shaped with its lowest point constricted and depressed into the center of the float chamber. An orifice at the lowest point of the mixing chamber permits gasoline to come up into the latter, forming a small puddle when the engine is at rest, whence the name of the carbureter. A needle valve controls the orifice, and the float is adjustable to regulate the gasoline level, and therefore the depth and size of the puddle. There are no other adjustments, and all the air passes through the single U-shaped mixing tube.

The theory of this carbureter is that at low speeds no suction is required to feed the gasoline, since gravity tends to keep the puddle full. The liquid gasoline in the puddle is swept upward and along the walls of the induction pipe, and evaporated on its way to the engine. At medium speeds the pnddle is wiped out, but the flow is still assisted by gravity. At high speeds the action is practically that of the ordinary spraying type. In practice, carbureters of this type work very successfully through a limited range, which perhaps is as great as the range of the average engine. If, however, the engine is exceptionally flexible its demands may exceed the automatic range of the carbnreter, with the result that the mixture is strangled and overrich at high speeds. If a larger carbureter is substituted, it works well at medium to high speeds, but not at low speeds, owing to the gasoline and air not being sufficiently mingled. By attaching an auxiliary air valve to the intake between the carbureter and the engine this limitation is overcome. In other respects the carbureter is extremely simple and easily adjusted, although considerable nicety is required in getting the gasoline level exactly right.

The foregoing paragraphs have dealt only with the absolnte proportions of gasoline and air, and have assumed that whatever gasoline the carbureter delivered was diffnsed and burned. In reality both of these assumptions may be wide of the truth,



Group of Modern Carbureters, Showing the Variations in Construction. Duryea, Bennett and Willet



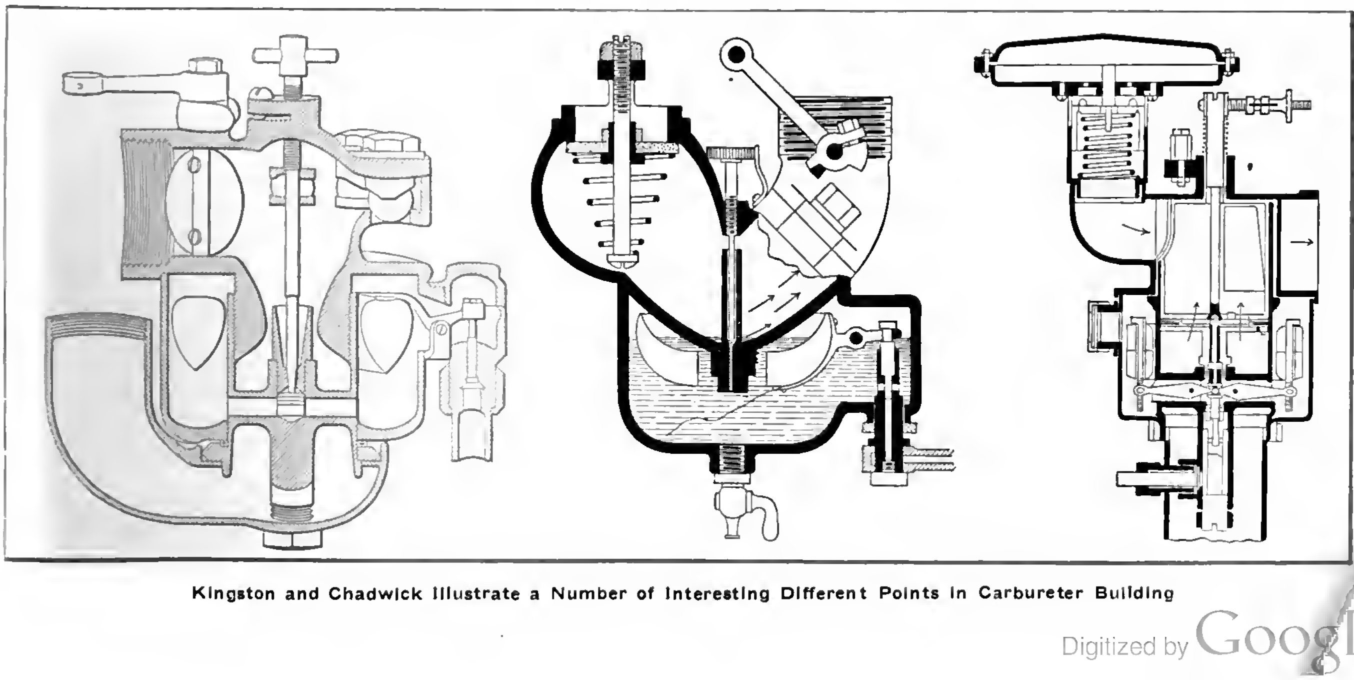
More Examples of Modern Carbureter Construction. On the Left Breeze. On the Right Carter. Between Anderson

especially in large carbureters with a single spraying orifice. At low speeds the gasoline may not be properly broken up by the air stream. At high speeds, while broken up, it may not have time to evaporate and diffuse. It is certain that with a large proportion of the carbureters in common use some of the gasoline fails to find its necessary quota of air for combustion, and therefore goes through the engine unburned. The first difficulty, that of atomization, is partially met by having two or more separate spray nozzles of graduated sizes, of which first one, then another, comes into action. Such a carbureter was shown in Fig. 4, last week, in which *A* is the main throttle and *B* the auxiliary throttle. The two throttles are linked together in such a manner that *B* remains closed till *A* has opened sufficiently to take as much mixture as the small spray nozzle can furnish.

The question of converting liquid gasoline into vapor and commingling the vapor with the air is not simply a question of atomization, but also of heat. Gasoline evaporates rapidly, but it absorbs heat on doing so. So far as it is in spray form this heat is readily supplied by the air itself; such, however, of the gasoline as forms a film on the walls of the induction pipe is best evaporated by heating those walls, and the conventional water-jacket of the carbureter itself is by no means sufficient for this purpose. Recently various automobile builders have adopted the idea of drawing the mixture through a cored passage in the cylinder casting on its way to the intake ports. A still better plan appears to be to introduce the diluting air after the gasoline vapor and primary air stream have been thoroughly mingled. This involves placing the auxiliary valve as close as possible to the cylinders, for example, at the branch of the intake manifold, with the throttle so placed as to compel intimate commingling of the pure and carbureted air streams. The pipe from the carbureter to the throttle is then hot water-jacketed, or else the primary air stream itself is highly heated and a very rich mixture produced. The diluting stream is then sufficient to cool the mixture so that power will not be lost by needless rarefaction of the charge.

The problem of atomizing the gasoline has been approched from another angle in several devices comprising essentially rotating fan wheels which were supposed by their rotation to commingle the air and gasoline. The early devices of this sort appear to have been failures, for the simple reason that while the fan rotated the air column passing through, it did not. It would have been more logical and effective to make the fan stationary. Recently, however, the fan has been used in a different way, as a means of imparting rotation to a coarse-wire screen through which the mixture passes, and which by its violent rotation breaks up any liquid particles of gasoline impinging on its meshes.

Whatever the ultimate solution of the carbureter problem may be it is certain that much less gasoline will be found necessary than is to-day required by the average car. Such feats as the running of a 35-horsepower six-cylinder car 20 miles in an hour on a gallon of gasoline have been performed. We all know when our cars are tuned in some certain manner, whose exact theory we may be unable to trace, they will perform prodigies of flexibility and hill-climbing feats within a certain range of speeds. The carbureter of the future will certainly duplicate those feats through a much wider range of speed, as wide in fact as the construction of the engine is calculated to permit.



Kingston and Chadwick Illustrate a Number of Interesting Different Points in Carbureter Building

BROOKLANDS EASTER MEETING

LONDON, Apr. 2.—The first combined motor and aero race meeting was held at Brooklands track on Easter Monday, the combination bringing out a large and enthusiastic gathering. The flying machines had only one event, it is true, but five aeroplanes turned out, including monoplanes, biplanes and a single triplane. The winner was Mr. Maunders, who covered the half mile with his Bleriot monoplane in 52 seconds. Rather an ignominious ending greeted his performance, for just after passing the post, he collided with a large garden roller and smashed his left wing.

Of the car events, the principal features were the high speeds attained by the small cars and the general tendency toward the use of special boat-shaped bodies, in order to diminish the wind resistance. It was essentially a day for light 4-cylinder cars.

There were seven races, including the first and fifth, which were for motorcycles. The second was the Easter Junior Handicap, distance 5 3-4 miles, for cars of 25-horsepower R. A. C. rating and under. Then there were the Raglan Cup, 16-horsepower and under, at 8 1-2 miles; the March Handicap, less than 18-horsepower, at 11 miles; the Easter sprint race, at 2 miles, for cars which have been timed to do laps at a rate of 80 miles per hour, and the first 21 rating race at 8 1-2 miles.

The 20-horsepower Vauxhall (with four-cylinder engine, 90-millimeter bore) carried off two of the races, its best speed being 81 1-2 miles an hour. The next fastest winner was a 24-horsepower Vinot, which could only record 67 1-2 miles per hour.

Racing cars were conspicuous by their absence, and the only big chap to put in an appearance—a 120-horsepower Mercedes—spoilt its chance each time by a fierce clutch, which stopped the engine at the start.

A. C. F. Gives Up Its Aero Cla'ms

Paris, Apr. 4—After securing a date on the international program for a big aviation meeting at Rheims, together with a cross-country flying match from Rheims to Brussels, the Automobile Club of France has abandoned the entire project. It has decided, however to devote the $40,000 originally promised as prizes to the encouragement of aviation, the sum of $30,000 to be given to the first aeroplanist flying from Rheims to Brussels, a distance of about 180 miles, and $10,000 to the first airship making the trip from Paris to London.

It is not merely a change of program that the Automobile Club has made, but a practical abandonment of its claim to be an aeronautical authority. It fought hard to get a date on the international conference for what was practically a second edition of the Rheims meeting. England wanted the same date for a meeting at Bournemouth and secured it from the International Federation, but the French authorities tried to overrule the Federation, persisting in their date and menacing aviators with disqualification if they took part in the English meeting.

Difficulties arose a few days ago when it was discovered that the committee of the Automobile Club of France has not voted the sum of $100,000 originally spoken of as prize money. Indeed it appeared that while the other organizers had been obliged to give guarantees that they possessed the necessary prize money, no such precaution had been taken with regard to the Automobile Club, although the promises had only been made on the authority of individual members. A meeting with $40,000 prize money costs at least $50,000 to organize, with a doubt as to this sum being exceeded in receipts. The club was not disposed to risk such a big amount, and in order to save its honor proposed to offer $40,000 for the encouragement of aviation, without organizing an event itself.

The offer has not been received very graciously. If the Automobile Club can withdraw after giving a formal promise to hold a meeting, there is no reason why any other association having secured dates should not offer its total prize money in one sum for a trip from Paris to Pekin. The airship prize will not encourage anybody, for it will be taken by either Clément or Lebaudy, both of whom are building airships for England which must cross the Channel before being purchased. Without an organizer at the back of the Rheims to Brussels race the event is not of interest. To win it will necessitate a sum equal to the prize, for a 180-mile flight cannot be made without serious preparations.

Traffic Problems in Big Cities

IN VERY big cities, like New York, Chicago, and London, many of the problems of traffic, street cleaning, sewerage, and the like, which are insignificant in smaller places, become almost insurmountable. So, it is, in particular, with the traffic problem. Of the cities mentioned, London has perhaps taken up the automobile to a greater extent than any of the others. For this and other reasons, anything pertaining to that subject is always interesting to those connected with the automobile business.

Consul-General John L. Griffiths states that a suggestive report has just been published by a section of the British Board of Trade on a subject of perennial interest—London traffic. This leads Mr. Griffiths to review the subject:

The primary difficulty in handling the enormous and constantly increasing traffic arises from the manner of London's growth through the centuries. It was not laid out as Washington was, for example, according to a definite plan, but developed in this direction or that in response to the immediate pressing needs, and until recent times with little regard to future requirements. The result is an extremely picturesque city, but not one altogether adapted to the transportation needs of its vast population.

It is proposed now to make an extensive survey of the traffic necessities of the city, taking into consideration its possible future expansion with the view of establishing great arterial traffic thoroughfares for the purpose of relieving the congestion at the center, and of furnishing adequate communication between the center and the outlying districts. To show the need of such thoroughfares it is only necessary to mention that while there are 102 miles of boulevards and avenues 98 1-2 feet or more wide in Paris, London has only 8 1-2 miles; and while Paris has 42 roads radiating into the country, London, with a population twice as great, has only 20, and ordinarily they are narrower than the French roads.

The proportions of the London traffic problem are shown by the fact that 87,934 new buildings were erected in the county of London (the city embraces the entire county and portions of other counties) from 1897 to 1908, and by the further fact that in the same period 148 miles of new streets were laid out.

Additional Population—Passengers Conveyed

It is estimated that by the middle of the present year the population of greater London will number 7,500,000 people, of whom 4,873,000 will dwell within the county of London proper, and 2,627,000 outside. Upon a conservative estimate an annual addition of 100,000 may be expected to this population.

The experience of London is similar to that of all other great cities in that for many years past the population of the outer area has been increasing much more rapidly than in the central districts, and the difficulties of the traffic situation have been thereby seriously augmented. The following table shows the number of passengers carried from 1903 to 1908, inclusive, on the local railways, tramways, and principal omnibus lines, together with the average yearly journeys per individual:

Year	Local railways	Tramways (approximate)	Omnibuses (principal companies)	Journeys per head
1903	290,722,680	394,356,531	287,386,471	142.9
1904	298,638,750	431,813,839	288,965,214	147.6
1905	305,052,495	477,944,684	290,665,051	152.2
1906	329,521,648	508,700,269	291,563,048	158.8
1907	356,233,666	589,745,792	275,479,000	169.3
1908	399,666,339	638,013,841	340,000,000	183.1

It will be seen that the total number of passengers conveyed in 1908 was 1,377,630,180, as against 972,465,682 in 1903. The total number of passengers carried in 1881 was only 269,662,649. These figures, however, are not complete for they do not include the cab traffic, nor all of the omnibus traffic, and neither do they cover the great suburban traffic of the trunk railways.

Suburban Movement—Residential Figures

The average length of the individual journey is increasing as people move farther and farther out. The development in the facilities of transportation have not kept pace with the growth in population, and the time is approaching, it is predicted, when the increase of travel and the outward movement of the popu-

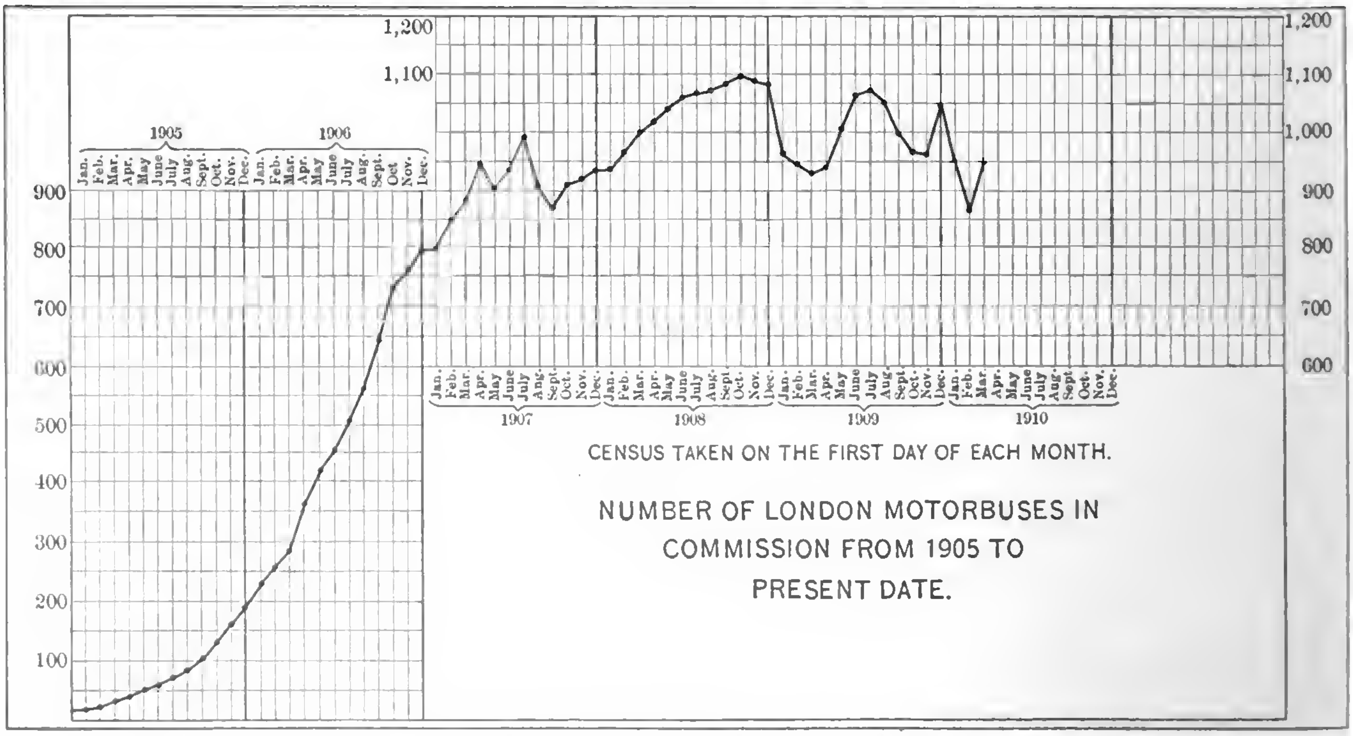

Diagram Showing Variation in Number of London Motorbuses in Service at Varying Times from 1905 to Date lation will each be checked unless provision is made to keep such facilities abreast with the growing demand.

While there were 43,538 empty houses and tenements in 26 of the 28 metropolitan boroughs of London in August last, there has been phenomenal increase in the population—in the past decade especially—of almost all of the outlying or suburban districts. The table below shows the shifting in traffic during the last few years, the figures given being those for eight selected points in a single day in a thickly populated residential portion of the city of London:

	1903.	1905.	1908.
Two-wheel cabs	5,114	5,260	5,042
Four-wheel carts	15,543	16,994	19,665
Private horse vehicles	43,790	47,833	29,967
Horse omnibus	32,790	32,661	15,216
Motor omnibus	......	537	10,914
Cycles	7,509	11,717	18,002
Private motor cars	1,064	3,260	6,961
Commercial motor cars	168	219	1,163
Taxicabs	......	......	19,718
Total vehicles	105,978	118,481	121,648
Foot passengers	354,983	309,137	329,985

The significant feature of this table is the striking increase in five years of the use of motor omnibuses, private motor cars, commercial motor cars, and the taxicabs.

Tramways Versus the Motor Bus

Tramways, as far as London is concerned, it is believed, have practically reached their limit of development, but the motor omnibus is probably only in its infancy. In narrow streets the speed of the tramway is greatly reduced, and municipal authorities, it is stated, have been compelled to appeal to ratepayers to patronize their own tramways. In the case of the omnibus, if a

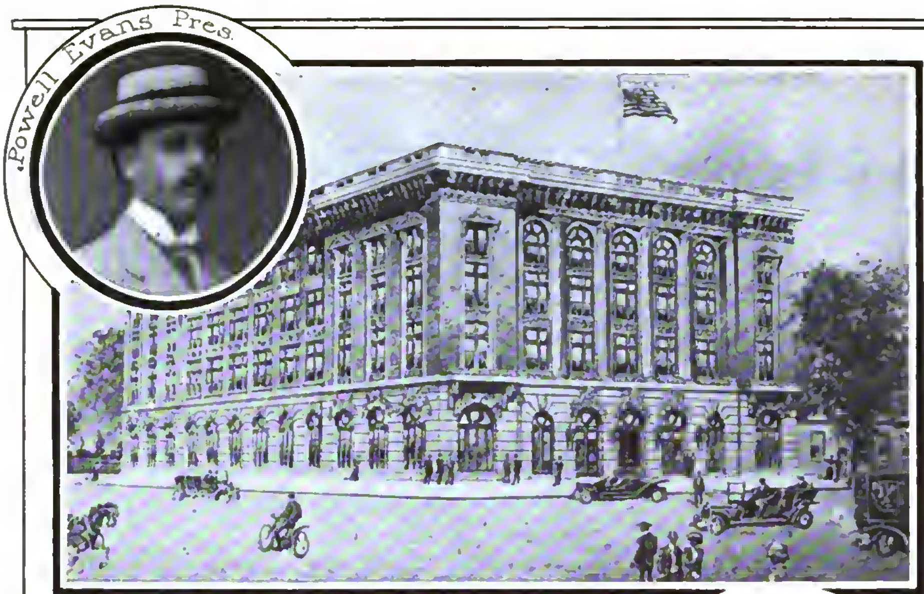
Data of Acceleratio

ENGINEERS are usually such busy men that little opportunity is offered them for original tests and other research work. So it is that there is a marked scarcity of data available on the pert subject of acceleration and braking tests of automobiles. For this reason any scrap of knowledge pertaining to this subject is carefully treasured, and with that as an excuse, the following remarks from an English contemporary (*Motor Trader*) are reproduced:

A correspondent has given some data from measurement tests of acceleration in starting and of retardation by braking that have some interest to the motor vehicle user. The writer tested steam and electric tube trains and tramcars, as well as motor buses and motor cabs. The readings were taken from an Elliott accelerometer and due allowance was made for gravity effect whether for starting or stopping. On the motor-omnibuses tested the starting acceleration varied considerably, but a typical case was 2.5 ft. per sec. per sec. on the first speed, 2.0 on the second, and 1.5 on the third. In each case the acceleration fell off quickly as the omnibus gained speed. Motor cabs, the author says, start at almost any figure, and the effect is more of the nature of a jerk than a steady acceleration. This is due to the sudden liberation of the kinetic energy of the rotating clutch and engine parts when the clutch is let in. The maximum steady acceleration observed was 4.0, but it rapidly fell to 2.0 and more slowly from that figure as the cab got up speed.

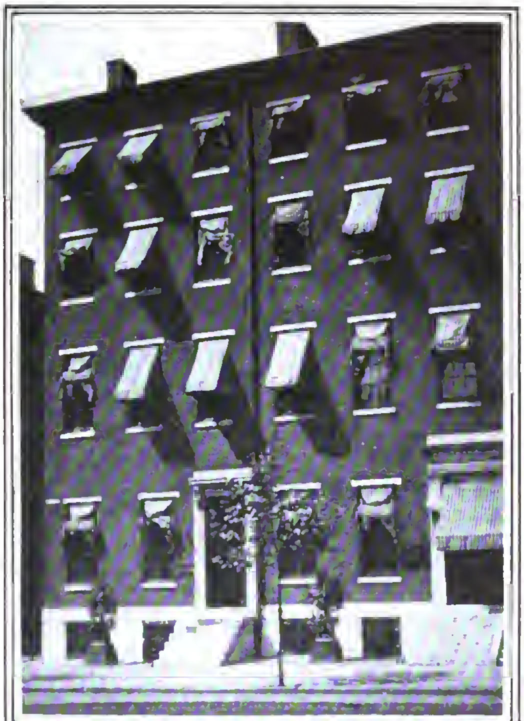
The starting acceleration of motor cars of high power was found to be more difficult to read. The acceleration was determined by measuring the time taken to get up to a definite speed (as read on the speedometer) and by dividing this speed (in feet per second) by the time taken in seconds. The resulting figure was the average acceleration in feet per sec. per sec. With a touring car fitted with a limousine body, the average acceleration at starting was found to be about 3.0, but on a light five-seated car figures as high as 7.0 were read,

AUTOMOBILE CLUB of PHILADELPHIA



Proposed Club House and Garage

Dr. D. Braden Kyle



Present Quarters

W. O. Griffith

J. J. Seeds

THE pioneer motoring organization of the Quaker City, the largest body of its kind in that part of the country and one of the largest in the United States, is the Automobile Club of Philadelphia. Without any fixed sporting feature, save the Brazier trophy run, which has expired by limitation on account of the permanent winning of the plate by one of the members, the club has rolled together a membership of nearly 1,100, and thus presents a formidable force in the field of influence as a legislative factor.

The club roster includes the names of many of the leaders of the Quaker City in finance, business, professions, and in the social world. Its single object is to advance the cause of the automobile as a pleasure vehicle, and under this general principle all the various heads and subdivisions of activity in the interest of the automobile are included.

The automobile trade is subordinated to the automobile in the life of the club, despite the fact that an appreciable section of the membership is identified with that trade. It is said that many of the members who are now engaged in the automobile business have become so since they became members of the club, and that it is their interest in motoring and their ownership of automobiles, rather than business considerations, that holds them. But the work of the club is strictly businesslike. The cozy little offices at Broad and Locust streets fairly teem with activity all day long. Obliging officers are on duty throughout the day to dispense route directions, touring data of detailed character, information as to accommodations of hotels and garages at any point within the sphere of activity of the club and also in issuing New Jersey licenses and permits that are recognized in other neighboring States. The present quarters are small, consisting of only three rooms, but the club contemplates building a home in the near future that will rival anything of the sort in the world.

In some central location, probably not far from Broad and Chestnut streets, the Automobile Club of Philadelphia is laying its plans to build a clubhouse and garage which will cost $400,000. Of this vast sum $200,000 has been provided by a tentative first mortgage and the remainder is to be raised by a bond issue bearing 5 per cent. interest, which will be sold to members of the club and others who may become members.

Already $66,000 has been actually subscribed, and practically all of the subscribers have expressed a willingness to double the amount of their bids. The bonds will be dated April 1, 1910, and will fall due October 1, 1940. The total amount of the issue authorized is $300,000, but it is provided that only $200,000 will be sold at this time. The bonds are coupon securities, the interest coupons being payable semi-annually. The denomination is $500. The club retains the privilege of redeeming the bonds April 1, 1915, at par and accrued interest.

The site of the new clubhouse will contain about 25,000 square feet of ground, upon which will be erected a five-story building in which will be embodied the most advanced ideas of construction. Space will be provided for 300 to 400 cars. The garage will be open continuously, and will be available at all times to members. According to the plans, the most modern equipment and machinery will be installed. Devices for measuring gasoline and oil, facilitating accuracy in accounting and rapid delivery, vacuum cleaning, storage of oils, compressed air for tires and other facilities will be included in the equipment of the garage.

Another feature of the clubhouse will be its chauffeurs' bureau. This enterprise has been started already, but in the new quarters it will be developed to a much higher degree. There is always a demand for trustworthy and competent drivers and chauffeurs, and it is the practice of the club to get the men to register and submit references. These references are carefully investigated and when the name of a chauffeur is listed by the Automobile Club of Philadelphia, prospective employers have the satisfaction of knowing that those men whose names are presented are thoroughly reliable. The drunkard and the careless driver who has been mixed up in joy-riding or who has capsized, damaged or destroyed a valuable car will be at a disadvantage in securing employment, while, on the other hand, those whose records are clean and show efficiency will have a much broader field.

A machine shop of the highest type will be provided for the use of members, where any sort of repair work, construction or experimental research will be undertaken at moderate cost. A feature of this department will be a section devoted to the members' chauffeurs, as a repair room.

The club's supply department, acting as agent for members, will provide all supplies at club prices, and will ship supplies out of town on order of any member requiring such service. The club garage will be run strictly on the "no-commission" basis, which will undoubtedly prove a refreshing innovation.

The reasonableness of the big plan has been amply demonstrated and worked out in detail by its projectors. It is estimated that there will be at least 300 cars stored in the garage by members. The present facilities for garage work in Philadelphia are lamentably deficient, and the club looks for even more business than is indicated in the foregoing estimate. But on that basis and charging the very moderate figure of $20 a month, the income would be about $72,000 a year. The estimated profits on repairs, accessories, oil and gasoline are placed at only $22,500.

That would give a total income of at least $94,500 a year, and the expenses of the garage would be about $40,000. Deducting the fixed charges for paying the bond interest and taking care of unforeseen contingencies as they may arise, the balance would be sufficiently large to provide a sinking fund of $25,000 a year to pay off the principal of the bonds.

Aside from the garage, the clubhouse will contain elaborate quarters and accommodations. These will include a ladies' room, common room, lunch room, shower baths, library, map room, lockers and every other good feature of the modern clubhouse. The building will be of standard, fireproof construction, and will be of permanent and artistic value to the city for many purposes. No insurance will be necessary except for the cars themselves. On the plan thus formulated, the cost of maintaining an automobile will undoubtedly be lessened materially to members.

It is expected that the financial details will be completed this spring and that actual construction will commence before the end of the coming summer. The club intends to hold its next annual meeting March 15, 1911, in its new home.

As has been mentioned, the club does not go in for racing to any marked extent. The Brazier trophy, which was donated by one of the members as an award for the winner of a 100-mile tour, was the only fixture of the organization that might be deemed to be a contest. But some time this spring or in the early summer, a three-day road tour for the members is being arranged. One of the most popular of the tentative routes under consideration is a triangular course from Philadelphia to Wildwood; Wildwood to Atlantic City; Atlantic City to Philadelphia by way of Lakewood. One day would be spent on each leg of this triangle, and a most enjoyable tour would be thus afforded. Suitable trophies are being prepared for the winners. It is likely that the tour will be held in the early part of June.

One notable service performed by the club has been its map and sign work. The territory under its immediate jurisdiction consists of twenty-one arbitrarily formed sections, each 36 by 42 miles, and extending to Frederick, Md., on the southwest, to New York State line on the northeast. In ten of these sections immediately adjacent to Philadelphia the map work has been completed, and the detailed information digested and tabulated by the club. Work on the remaining eleven sections is progressing, and much has been accomplished in the way of placing readable signs at appropriate places on the roads.

On account of the strangely muddled state of the automobile laws, there is more or less friction between motordom and the authorities everywhere in the world, and in view of this condition the Automobile Club of Philadelphia makes a specialty of its legal services to its members. S. Boyer Davis, secretary-treasurer of the club, is its counsel, and during the past year he has been called upon to go to court in 125 cases wherein alleged violations of the law were at issue. The result of these prosecutions and court proceedings has been generally favorable.

In handling these cases, Mr. Davis was aided in large measure by the fact that the Automobile Club of Philadelphia has always striven to inculcate the fundamentals of courtesy of the road in the minds of its members. For instance, under the unwritten rules of the club governing the running of the Brazier trophy contest, the participants were required to stop their engines when approaching a nervous horse. They were also cautioned not to kill any dogs and chickens, and to preserve a fine, careful attitude with regard to human life and comfort as applied to pedestrians and other users of the roads.

The public is becoming familiar with these rules, and each month finds the pathway of the motorist a trifle easier as a result of the more cordial understanding engendered thereby.

The club was incorporated November 1, 1900, and was formally organized May 25, 1901. It is thus the first of the Philadelphia motor clubs in point of seniority. Its quarters were located in the Land and Title Building for several years, and May 1, 1909, the present rooms were secured.

The officers are: Powell Evans, president; Stedman Bent, vice-president; S. Boyer Davis, secretary, treasurer and counsel. The directors are the officers and Henry P. Baily, Jacob J. Seeds, D. Braden Kyle, W. O. Griffith, Howard Longstreth, Herbert Morris, W. W. Atterbury and Robert K. Cassatt. The standing committees are presided over as follows: Club Relations, Stedman Bent, chairman; Law and Ordinance, S. Boyer Davis; Touring Information, W. O. Griffith; Good Roads, Howard Longstreth; Membership, Henry P. Baily, and Club Garage, D. Braden Kyle.

Membership in the Automobile Club of Philadelphia includes membership in the A. A. A. and the Pennsylvania Motor Federation, the state organization which has been so active in working for the betterment of automobile conditions in Pennsylvania.

Slide Valve Engines and Drill Sizes

Editor THE AUTOMOBILE:

[2,232]—I have been much interested in the articles appearing in "The Automobile" from time to time relative to the sliding type of valve, as the Knight. Please tell me the date of your paper in which there was a description of this engine. I have seen it but fail to find it now that I want to refer to it. Will you kindly tell me also the drill sizes of the A. L. A. M. taps?

New York City. ARTHUR L. CARRON.

The Knight engine has been the subject of several articles in THE AUTOMOBILE in the past. First, in the Oct. 22, 1908, issue it was described fully, with reproductions of working drawings of the engine. Recently, it was treated from another and more recent viewpoint. This was in the issue of Feb. 10, 1910. In the latter, the lubrication system was analysed, and power curves from several thorough tests were given, showing by comparison the power from a Knight slide valve engine and an engine of equal or equivalent size equipped with the ordinary poppet valves.

Drill sizes vary with the number of threads per inch, because the latter alter the bottom diameter of the hole or belt, small threads having a larger root diameter for the same nominal diameter than coarse threads. The A. L. A. M. screw threads being all fine threads, call for different sizes than the regular or coarse threads. The sizes to use are as follows:

A. L. A. M. Standard.		Bottom Diam. of Bolt.	Drill Size.	Drill Size for U. S. S. Std.
1/4	28			
7/16	20	.375	23/64	Q. S, or 11/32
1/2	20	.435	27/64	3/8, 13/32, or W.
9/16	18	.490	31/64	7/16 or 29/64
5/8	18	.5525	35/64	31/64, 1/2, or 33/64
11/16	16	.6065	19/32	9/16 or 37/64
3/4	16	.669	21/32	39/64, 5/8, or 41/64
7/8	14	.7815	25/32	23/32 or 47/64
1	14	.9065	29/32	53/64 or 27/32

Results of Changed Gearing

Editor THE AUTOMOBILE:

[2,233]—In your answer to letter number 2,161, among other things you say, "In making the change it will be found that the lessened speed is not any too agreeable, etc." Please explain through the columns of "Letters Interesting, Answered and Discussed" what you mean by "not too agreeable," and how this change is brought about by the change in question. I do not understand it. I am having the same experience with my car, which also is geared 4 to 1, same as the car of Mr. Power. While it runs perfectly on the level road, it lacks the stick-to-itiveness when it comes to sand or hills. A. E. HACKER.

Monrovia, Cal.

Reference was had in the answer to the letter above referred to to the fact that when one has become used to a certain speed of car from many months or years' use of it, a change introducing a different and slower speed causes trouble, in that the owner or driver can not immediately adjust himself and his ideas of speed formed during the past use of the car to the new maximum pace beyond which it is possible to go. In short, after being used to traveling at, say, 20 miles per hour, it is hard to get used to going but 16 miles per hour with the engine going just as fast as before, this being the result which a change from a 4 to 1 reduction gearing altered to 5 to 1 would give.

Connecticut Laws, Horsepower, Etc.

Editor THE AUTOMOBILE:

[2,234]—In looking over the pamphlet of the Secretary of State of Connecticut regarding the laws of the State pertaining to automobiles, I note a proportionate deduction for time on auto registration fee after June, but none is mentioned before. Why this should be I do not understand. I cannot see why a deduction for the three months after January should not be made as well as for the three months after June. Could it be that the statute should have read January instead of June? And if this could be established as the intention of the legislator who drew the bill, could the courts of this State remedy the self-evident injustice? Another feature that I note is that some cars are rated by the manufacturers at a higher power than by the State and by the A. L. A. M. rating. For instance, Buick is rated by the manufacturers as 22 horsepower, while the State makes it 16 horsepower. And the Ford N is rated at 15 by the company, while the State rates it at 22 horsepower. Now, can there be this actual variation of working power or cars? The Ford Motor Company rates Model S at 15 horsepower and T at 20 horsepower, while the State calls both 22. If there is this difference in the actual working power, will you explain why? It has been remarked to me that small cylinders clog and do not give the actual power indicated by the A. L. A. M. as well as large cylinders. Will you inform me if this is a fact? What should be the size of the exhaust pipe of cylinders 3 3-4-inch diameter and 4-inch stroke? Would a larger stroke need a larger pipe?

Nichols, Conn. W. T. K.

In the language of the registration act mentioned, the idea is quite clear. The bill says: "An applicant who does not file his application until after the first day of June shall be entitled to a pro rata reduction in the fee for such registration calculated to the first day of the month in which the application is made." The intention is that every owner and driver shall register on January 1, being thus able to use his car for the entire year. If, through late purchase or otherwise, the owner does not file his license until the year is half over, he will then have lost the use of the State roads for automobile purposes for that half of the year or longer. Recognizing this loss, the State partly compensates the owner for this by reducing the amount of fee to be paid for that year by an amount proportionate to the number of months lost.

As a basis for the taxation according to horsepower, the State has selected the A. L. A. M. formula for rating. You will find on looking up the list and the exact statute language that this is there so stated (Sec. 2, Chapter 221, Public Acts of 1909). Since not all makers adhere to the formula, the advertised rating and the State rating naturally differ. As long as makers continue to overrate or underrate their motors, this will continue to be the case. The confusion in the case of the Ford models is but natural. However, the same bore and stroke are used on the N, R, S and T, so that the State would rate them alike.

Small cylinders, or, for that matter, large cylinders either, do not clog up. If well constructed, the formula power should be developed at the rated piston speed. Exhaust pipe sizes are proportioned on the basis of cubical capacity and gas speed, a figure being set for the allowable speed of the gas. This will determine the pipe size, and any alteration in the capacity or speed, such as a longer stroke, will of course change the result. If in the instance mentioned the stroke was changed to 4½, the size of the pipe should be increased, or else the gas speed will be greater.

One Man's Idea of Car Assembling

Editor THE AUTOMOBILE:

[2,235]—It seems to me that it will be a great draw on our resources to maintain the automobile. Other lines are doing poorly now, while the automobile only makes living more expensive. The people taking to the automobile business "soak" you all they can. We are handicapped for men that can make repairs, without extortion as to the prices they charge, those that know get positions with the makers, leaving only inexperienced men to help repair the automobiles. This is a case of the blind leading the blind. Repair men are incompetent, and their prices are unreasonable. Builders are putting their automobiles together in a hurry, leaving several faulty places to be looked after by the buyer. I would want to see my next automobile assembled so that things were not rushed and that the pieces were a perfect fit. Piston rings leak oil, others are ground away, coil has tin in it. Dampness prevents it from working. What we need is a bond of indemnity with each and every machine. SAMUEL ASHCRAFT.

Swedesboro, N. J.

About That Radiator Trouble

Editor THE AUTOMOBILE:

[2,236]—We are the manufacturers of all of the repair parts for the Northern, Wayne, and Queen cars, and have purchased patterns, drawings, and gigs, etc., from all of the companies that manufactured these cars, and the writer has noticed from time to time that there are inquiries and answers relative to cars for which we are supplying and repairing parts.

We wish to refer you to an article which was a question put to you by R. E. Heinish, of Newark, N. J., with whom I have had considerable correspondence, especially relative to the subject on which he was asking for information in your copy of February 17. You answered his inquiry on page 374.

Now I disagree with your information relative to the trouble Mr. Heinish has had with the water circulation. The radiators on all Northern cars were theoretically designed to more than take care of the amount of water necessary for cooling the motors installed in their several different models. The one in question is a 1906 model of car, of which there are some nine hundred cars in continual service, and I absolutely know that 90 per cent. of them are giving no trouble whatsoever with the heating of the motor. I have found in my four years' experience that the overheating was due in nearly every case to the water pump being worn, or the internal impeller wheel or blades becoming detached from the driving member. I find a few other cases in which heating troubles occur when the inner lining of the hose connections had become rotten so that the inner lining of canvas would fall down and clog the passage of water. Large pieces of this lining also became detached, and with the flow of water were carried into the radiator tubes and logged there, causing stoppage.

I have explained the above in numerous letters to many of our customers and also Mr. Heinish, and I will positively guarantee that the type of radiator with the same size inlet and outlet connections can be made to cool the engine if the water pump and water lining of the hose are put in first-class condition.

So you see I very much disagree with your advising Mr. Heinish or any other person owning this type of car to purchase a new and larger radiator, which will mean added expense and delay and in the end not rectifying the trouble.

We would be pleased to have you explain this in the next issue of "The Automobile." Thank you for the courtesy of doing same.

Detroit, Mich. AUTO PARTS MFG. CO.,
L. A. AUSTIN.

Attention of all owners of Northern cars, as well as Queen, Wayne and De Luxe cars is called to the above, the company having made the deal which gave them the De Luxe patterns, jigs, etc., since the above letter was written.

In one slight particular it is necessary to disagree with Mr. Austin, in that the radiators could not have been designed to "more than take care of the amount of water necessary for cooling the motors." This is but another way of saying that the radiators are too big. If this were so, the engines would run too cold, which, as is well known, they do not do. There is a great deal of difference between having just the right radiator capacity and having too much capacity, so as to lower the efficiency by running the engine cold.

Dispute Over Long Race

Editor THE AUTOMOBILE:

[2,237]—Please decide for me the following dispute: In talking about the race last season from New York City to Seattle, I contend that the Ford Model T car won the race and was awarded the race; a friend of mine contends that while the Ford was the first car into Seattle, it developed that the driver of the Ford had changed engines at some Ford agency and later the race was awarded to another car. Please set us right on this, and if another car was awarded the race, give make of car. C. H. MOULTON.

Beach, S. D.

Your friend was right. The Ford was the first car into Seattle, but was afterward disqualified, and the race awarded to the Shawmut car, which came in second. It was proved that the Ford changed an engine, just as your friend contended, and so the car was disqualified.

The ultimate winner, the Shawmut, was made in Massachusetts, by a firm which is now out of business or else just undergoing reorganization. But a very few cars of this make were ever turned out, and there were no spare parts to be had. Under those circumstances, it was a very courageous piece of work to enter the hard race and, moreover, see it through.

Law of the Road, or Rules Governing Travel on Highways

By XENOPHON P. HUDDY, LL. B.

THE "law of the road" is constantly and more frequently being applied since the comparatively recent development of the automobile and the increase of motor vehicle travel on the public thoroughfares. Therefore it is proper that the automobilist should thoroughly understand what those rules are which make up the law of the road. We will first ascertain what the term the "law of the road" means.

DEFINITION OF LAW OF THE ROAD

The "law of the road" is a phrase used to designate all of the general rules by which travel on the ordinary land highways is governed.

ORIGIN OF THE LAW OF THE ROAD

Originally the law of the road constituted mere custom and it found its inception in custom. In England, for example, it became a habit for drivers of vehicles when meeting and passing to turn to the left, therefore, to-day there the rule is to turn to the left. This custom finally became so well recognized and established that it became a part of the common law, which later has been enacted into statute. In the United States, as everyone well knows, the rule is directly opposite to that prevailing in England, which is to turn to the right upon meeting and passing. Why, here in the United States, we adopted a different rule is not certain, although several explanations have been suggested.

It was out of custom, therefore, that this law of the road, embodying all of the rules governing highway travel, arose. Being the customary law it became the common law, and subsequently the States in this country expressly codified these rules to a certain extent.

RULES OF THE ROAD SHOULD BE SIMPLE

The law of the road is not complicated and should not be made too complex. If we are to make traveling on the public highways safe, the rules governing it must be extremely simple and easily and quickly to be applied. This is one argument in favor of automobile legislation which is not complicated. I am not now speaking of traffic regulations, which will be considered later on. One who drives an automobile should be so familiar with the rules of the road that they may be applied without thought. Still, thought should prevent their application when necessary, inasmuch as the law does not require the rules of the road always to be followed. In fact if a driver insists upon following the general law of the road when to do so would injure another, he is guilty of negligence, as it is his duty to deviate from the rule when occasion demands it; so it will be seen that the rules of the road are not fixed and, as an instance of this, I cite the case where one driver meets another and the one proceeds to turn out to the right to pass, but finds that the other driver is turning to the left to pass. In this case it is the duty of the former to turn to the left, if to do so will avoid a collision.

EQUAL RIGHTS ON PUBLIC HIGHWAYS

One of the primary rules to remember, and which is fundamental and at the basis of all rights on the public highway, is that all lawful users of the public highways have equal rights thereon. This means that the automobile, the horse-drawn vehicle, the street car and the pedestrian each equally has as much right to use the public highways as the other and each should respect the other's right. Neither has any superior right over the other and if one vehicle encroaches upon the rights of another it is done so unlawfully.

OVERTAKING AND PASSING

Another primary and general rule of the road is that overtaking vehicles should pass to the left of the preceding vehicle. As a corollary of this rule the preceding vehicle should reasonably and seasonably give way and allow an overtaking vehicle to pass to the left. The right of a preceding vehicle to pass one ahead is supported by a recent decision of the Court of Appeals of the State of New York, the first time this question has been squarely determined in this country. Quoting from the official report of this case, the following may be said to be the law:

"In the case of two cars traveling in the same direction the front one has the superior right and may maintain its position in the center of the highway if there is sufficient space on its left, as prescribed by the Motor Vehicle Law, for the approaching car safely and conveniently to pass. If the position of the forward car in the center of the highway does not leave room for passing, then it must, if practicable and convenient and upon request or equivalent notice, turn aside so as to make room. If at the time there is not sufficient space to do this, it may wait until a convenient place is reached. The circumstances might also be such that a jury would be justified in finding that it was extremely unreasonable for a slow-moving car to refuse to stop, if requested, and let the other pass."

Since the automobile has come into general use, other rules of the road have appeared, such as the necessity for giving a warning signal upon approaching a corner, particularly where the view is obstructed. Warning signals should also be given to call the attention of other users of the highways to the fact that the automobile is proceeding under circumstances where reasonable care demands the giving of signals.

STOPPING THE CAR

The law of the road has not solely to do with actual traveling. It is as necessary to be careful and cautious in stopping an automobile and remaining stationary as it is to proceed. There can be no monopoly of the public thoroughfares, therefore it is an infringement upon the rights of the public to stand in the street or on a road for an unreasonable length of time. Where traffic is thick the time is much shorter which is allowed for a vehicle to remain stationary. In leaving an automobile on the street, due care should be taken by the operator to leave it in such a condition that it cannot be started by intermeddlers. If due care is exercised in this respect no responsibility is incurred by the driver or owner of the machine if children come along and start the machine which, uncontrolled, runs into either a person or a vehicle on the public highway.

EQUIPMENT AN INTERESTING SUBJECT

Equipment also constitutes a subject which the law of the road controls. The equipment of an automobile must be lawful and to be lawful it must be safe. The statutes of the various States provide that brakes, lights, signaling devices, mufflers, etc., must be had. The term "equipment" was covered by the old common law by the term "good tackle," which was used to designate such articles of equipment as harness, buckles, shafts, whiffletrees, etc. A vehicle which is used and which lacks legal equipment or good tackle, if it collides with a person or other vehicle on the public highways by reason of it not having good tackle or legal equipment, legal liability will be incurred by the driver or owner. Proper lights should also be carried, not only on automobiles, but horse-drawn carriages should have them.

ROAD-WORTHINESS

Before leaving the subject of equipment and good tackle, it should be mentioned that the vehicle should be generally road-worthy. Road-worthiness covers in a general way the ability of the vehicle to travel and carry its load without danger to its occupants or others using the public highways. It has nothing to do with the ability of the vehicle to proceed. Whether or not an automobile is road-worthy is generally a responsibility which the manufacturer assumes toward the purchaser and it may be said that every manufacturer of motor vehicles warrants that the machines turned out by him and placed on the market are road-worthy. The warranty does not extend beyond the first purchaser.

WHAT THE LAW OF THE ROAD APPLIES TO

The law of the road applies to automobiles as well as horse-drawn vehicles. It does not apply in many of its particulars to street cars. They run on rails and cannot be steered away from the established track, but other vehicles must, however, pass street cars upon meeting and overtaking them, following the same rules that apply to other vehicles which have more freedom of control. Of course, an automobile should stop when the street car in front of it stops to let off passengers.

PEDESTRIANS, CHILDREN, ETC.

The law of the road does not, however, apply to pedestrians. They are not compelled to follow the rules which are embodied in the law of the road. People riding horseback also are not compelled to obey the rules of the road. Of course, the proper place for pedestrians to cross the street is at the regular customary crossing, although it is not negligence for a pedestrian to cross at other places, where it is reasonably safe for him to do so. It has even been held not to constitute negligence for a pedestrian to stand in the road and talk to the driver of a vehicle. In such a case it is the duty of approaching vehicles to look out for the safety of the pedestrian.

Particular care should be exercised by automobile drivers not to run down children who are playing in the street. It is to be conceded that children should not be allowed to play on the public highways; nevertheless, if they are there it is the duty of automobilists to look out for them, since their tender age cannot be held to exercise as high a degree of care for their welfare as in the case of adults. No amount of sounding the horn of an automobile or giving of any other signal will warrant or excuse running down a child or pedestrian.

The mere fact that the pedestrian is blind or hard of hearing will not excuse an automobile driver from negligently running into him.

Where an old man with defective eyesight was traveling south and met an automobile traveling north, and in attempting to get out of the way jumped toward the east and the machine turned toward the west, and the front hub on the east side struck the plaintiff, injuring him, it was held that the complaint was sufficient where it charged that they were riding in possession and control of the auto, and carelessly, negligently ran and operated the same at a high and dangerous rate of speed on the west side of the highway and knocked the plaintiff down and dragged him across to the opposite side of the highway and ran over him. It was also held that the complaint was not defective in not charging that they could see the plaintiff or that there was light enough to see him.

The rule that one must turn to the right on meeting another vehicle was held was not to obtain as to foot men. It was further held that it was not material on which side of the road the automobilists were driving. The evidence showed that they were aware of the presence of the plaintiff at a considerable distance from the accident; that they were driving at a high rate of speed, and that they did not change their course or slacken their speed.

To run an auto at a high speed toward a person, and so close to him that he is compelled or excited to flee from his path to keep from being run over, is an unreasonable abridgment of that person's right to the use of the road. It is claimed that one of the parties had nothing to do with the injury—that he was only riding in the auto and had no control of it; but the allegations of control in the complaint were not contradicted by the interrogatories and both parties were held liable. See Apperson vs. Lazro, 87 N. E., 97.

GENERAL RULES OF CONDUCT IN DRIVING

Aside from the express statutory rules governing travel on the public thoroughfares, there are general rules prescribed by the common law which should be followed. These rules are tersely and well stated in the following three paragraphs:

Every person driving upon the public highway is under a legal duty to observe, in the control and management of his vehicle, the exercise of reasonable care to prevent injury to others, and he is criminally and civilly responsible for the neglect or wilful failure to perform that duty. To create this responsibility, however, the law must cast upon the person sought to be charged the legal obligation to do the act or perform the service the omission of which is alleged to be the direct cause of the injury.

If persons having the control and management of a vehicle, in which they are riding along a highway behind another conveyance, knowing the danger of a collision with the forward conveyance and the probable consequences flowing therefrom, recklessly and negligently, or wantonly and wilfully, allow the vehicle to run down and collide with the other vehicle, without using such means as are reasonably at their command to prevent the same, they will be held criminally and civilly responsibile for the result of their negligence or wilful omission of duty. If it is the cause of death they may be convicted of manslaughter.

Where the driver of a vehicle is not guilty of negligence and a collision on the public highway is the result of inevitable accident, or resulted from the vehicle becoming unmanageable without his fault, and uncontrollable by the exercise of proper care, there can be no criminal or civil liability. See Belk vs. The People, 125 Ill. 584.

TRAFFIC REGULATIONS

In considering the law of the road we should not leave the subject without directing our attention to traffic regulations, which are more or less local in their nature, and govern the moving and progress of traffic more particularly in the large cities.

Municipalities possess the power to enact and enforce these regulations, since they are for the safety, welfare and convenience of all who use the public thoroughfares. Many of the regulations are merely declaratory of the ordinary rules of the road. As an example of a very good system of regulating traffic, I am inserting herein some of the regulations of New York City, which are as follows:

RULES FOR DRIVING IN THE CITY OF NEW YORK

All drivers of vehicles are required to comply with these rules in order to facilitate traffic, prevent blockades, avoid accidents and loss of life, and diminish the loss of time and money due to the lack of observance of rules for the regulation of street traffic.

A vehicle meeting another shall pass to the right.

A vehicle overtaking another shall pass on the left side of the overtaken vehicle and not pull over to the right until entirely clear of it.

A vehicle turning into another street to the right shall turn the corner as near the right-hand curb as practicable.

A vehicle turning into another street to the left shall turn around the center of intersection of the two streets.

A vehicle crossing from one side of the street to the other shall make a full 180° turn.

No vehicle shall stop with its left side to the curb except on established cab, hack and truck stands, and in streets where and when one-way traffic is directed by white arrow signs.

No vehicle except in an emergency or to allow another vehicle or pedestrian to cross its path, shall stop in any public street or highway, except near the right-hand curb thereof and so as not to obstruct a crossing.

SIGNALS AT TIME OF STARTING OR STOPPING

In slowing up or stopping, a signal shall be given to those behind by raising the whip or hand vertically.

In turning, while in motion, or in starting to turn from a standstill, a signal shall be given by raising the whip or hand, indicating with it the direction in which the turn is to be made.

Before backing ample warning shall be given, and while backing unceasing vigilance must be exercised not to injure those behind.

No vehicle shall be used on any street or highway unless provided with lights and sound signals as prescribed by law.

GERMANY:—A. Seydel, Mohrenstrasse 9, Berlin.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

The labor problem in the centers of automobile activity is becoming just a little more acute every day and strange to relate, strike features are not prominent among the points with which makers of automobiles have to deal. In Detroit, for illustration, while there is a slight undercurrent which has a certain union labor sound, the fact remains that wages are high, hours are well regulated and conditions of sanitation are excellent.

The problems of magnitude are from rather unexpected quarters. Housing the men is becoming extremely difficult. There are not enough dwellings in Detroit for the men now employed, and more men are flocking to this center every day. It is not now unusual for men to pay $40 per month rent for dwellings that do not rate higher than apartments such as may be had in New York City for $25 per month, and while relief is approaching, as the result of extensive building operations, the fact remains that the automobile industry is growing faster than the accommodations.

❧ ❧ ❧

There is another phase of the labor problem that will not "treat" so readily. Toolmakers are growing more scarce, relative to demand, every day. Machine tools are being ordered in excess of the rate of production thereof and a secondary complication comes in through the migration of toolmakers from the haunts of machine tools to the automobile plants. What really happens is this: Makers of automobiles order machine tools to suit their needs and rob the tool builders of their skilled workmen at the same time.

The railroad companies are now investigating Detroit in order to determine something of the freight-car requirement for this year. One commissioner, after going over the situation, stated: "If the tales I hear about production are half true there will be a freight-car famine." It is possible that the reports are half true because the commissioner's exclamation was premature; he became confused after visiting less than one-half of the live plants. It looks as if the transportation companies should do more building and less investigating.

❧ ❧ ❧

It is not uncommon to hear men say that the expansion of the automobile business is confined to low-priced automobiles for popular consumption. This version should be taken with a grain of salt; there are relatively new undertakings that pass the $4,000 level, and in the light of experience these new efforts compare very favorably with $10,000 automobiles as they were had a year back.

❧ ❧ ❧

Commercials are occupying a large amount of attention just at the present time. It is a healthy sign, and users of this type of car are beginning to see light. It is very likely that the commercial automobile will come into its own before the end of this year, and the time is near at hand when "ironclad" guarantees will not be exacted. It spells failure to guarantee service for the reason that commercials will be grossly abused by the very men who have nothing to lose when service is guaranteed.

As a further evidence of automobile prosperity, prompt collections and easy money must be taken. A close scouting of this phase of the situation in Detroit leads to the conclusion that the automobile commands the respect of capital. This situation is being bettered by the promptness with which makers of automobiles settle for materials and accessories.

❧ ❧ ❧

At this time of the year there is much building going on in the various automobile plants, and from these building operations much is expected, both in the way of larger outputs, cheapened production as brought about by more suitable facilities, or the reverse of this latter—better production at the same price.

In this building work much may be learned also. Thus, to borrow a single idea from the building contractors, much building is now done on the basis of agreement with the contractor that the latter charge the owner cost plus a fixed profit. In this there is an idea for something new in the selling of automobiles. If any automobile builder would say to the people, "I will establish factory branches in all the larger cities and sell my cars direct to the public at cost plus a fixed profit, naming that profit exactly, whether it be high or low," such a manufacturer, particularly if his product be a low or medium-sized car, would be swamped with business. Further, if this maker threw his books open, as must the contractor doing business on this basis, so that the truth of his assertions, both as to cost and as to profit, could be readily proven or disproved, he would not alone do a temporary business of a volume which would paralyze an industry used to big figures, but could also be sure of a continuance of this immense business year after year.

MAIL AUTOS IN NASHVILLE DISTRICT

NASHVILLE, TENN., Mar. 28—In consequence of very satisfactory experiments Postmaster A. W. Wills has forwarded to Washington recommendations that collection of mails in the suburbs of the city be by automobile service. With his report, proposals from several local auto concerns for the performance of the service were forwarded. Major Wills found that by the use of automobiles for the collection of the rural mails. delivery was advanced twenty-four hours. Under the present system the last collection is made at 3 o'clock in the afternoon.

By the use of one machine the final collection was begun at 5 o'clock in the southern and western suburbs, the machine then returning to the office. A round of the northern section was made and a return to the post office, after which a third trip was made through the eastern section, the entire time consumed being two hours and fifty-six minutes with about 3,000 pieces of mail matter collected.

NEW AUTOMOBILE CLUB FORMED

Automobile owners in Greene County are forming a permanent organization, and will have headquarters at Waynesburg. The objects are, first, road improvement, especially the proper repairing and keeping up of the roads, and, second, the making of a map of Greene and Washington counties and posting signs to direct motorists. The club will be known as the Automobile Club of Greene County, and has elected the following officers: President, R. L. Hoskinson; first vice-president, Charles E. Dittman; second vice-president, T. N. Millikan; secretary, Dr. Earl Miller; treasurer, S. M. Smith. There are about ninety automobile owners in the county, and the club will affiliate with the State organization.

MICHIOAN AUTO TRANSFER COMPANY

The Mason, Dansville & Stockbridge Auto Transfer Company has been incorporated at Lansing, Mich., for the purpose of establishing an auto line to be run on schedule time between the towns named. Communication hitherto has been slow and difficult between these places.

843 HOBOES RESCUED WEBB JAY

Webb Jay, formerly known as one of the leading automobile drivers of the country and who met with a well-nigh fatal accident while racing at Buffalo in 1905, has had a rather unique experience as a result of the smash-up

One day recently a tough-looking specimen of the common or garden variety of hobo approached Mr. Jay, extended his grimy hand and said: "Gee whiz, I never'd a thought I'd a seen you here now, when I pulled you out of that mud-hole up in Buffalo with your legs and arms busted and pretty near scalped."

Several by-standers heard the remark and greeting and were astonished and not a little displeased when Mr. Jay delivered himself as follows: "Here's a half a dollar; beat it. You are number 843." It was explained later by the former driver that he had kept count of his alleged rescuers that day in Buffalo, all of whom required some trifling financial assistance, and up to date the number had been 843.

COLUMBUS CLUB PLANS RACE MEET

COLUMBUS, O., Apr. 4—The contest committee of the Columbus Automobile Club, of which Perin B. Monypeny is chairman, is canvassing the situation as to the advisability of holding a race meet in Columbus during the summer. The tentative dates given the Columbus club by the A. A. A. were unsatisfactory and the matter has been taken up by correspondence and other dates will likely be secured.

Negotiations have bee nopened with noted drivers and ndications are bright for a successful meet. Last year a small profit resulted from the meet and it is believed that the conditions are better this year.

ABSENT TAIL LIOHTS EARN FINES

From four to a dozen arrests are being made daily by the Columbus, Ohio, police department under orders received recently from Director of Safety McCune, ordering that all motor cars operated within the city limits be provided with the necessary lamps. Most of the arrests have been made because of the absence of a tail light. Fines have been imposed in police court.

Coming Events in the Automobiling World

Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.
June 20-July 6....Detroit, Mich., Industrial Exposition. Detroit Board of Commerce.
Jan. 7-14, 1911....New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.
Jan. 17-24, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Feb. 13-25, 1911..Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

Apr. 30-May 2....Philadelphia Roadability Run to Atlantic City, Quaker City Motor Club.
May 2............Flag-to-Flag Endurance Contest, Denver, Col., to City of Mexico.
May 5-7..........Atlanta, Ga., Track Races. Atlanta Automobile Association.
May 9-11.........Harrisburg, Pa., Fourth Annual Reliability Contest to Atlantic City and Return.
May 19-21........Hartford, Conn., All-Connecticut Reliability Contest.
May 21-22........Bay Ridge, L. I., Club's Endurance Contest Around Long Island, Crescent Athletic Club and Long Island Automobile Club.
May 30...........Bridgeport, Conn., Hill-Climb up Sport Hill; Automobile Club of Bridgeport.
June 4...........Worcester, Mass., Fourth Annual Hill Climb, Dead Horse Hill.
June 11..........Wilkesbarre, Pa., Annual Hill-Climb up Giants' Despair, Wilkesbarre Automobile Club.
June 15..........Cincinnati. Seventh Annual National Reliability Run for Glidden Trophy, through the Southwest.
Oct. 1............Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley, and Massapequa Sweepstakes.
Oct. 15...........Long Island Motor Parkway, Grand Prize, Automobile Club of America.

Foreign Shows and Races

Apr. 2-24.........Turin, Italy, Automobile Show.
Apr. 27-28........Brooklands, England, Two-Day Meeting.
May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.
May 25............"The American Cup," Argentina, Sociedad Sportiva Argentina, near Buenos Ayres.
May 28-June 9....St. Petersburg, Russia, Automobile Exhibition.
May 29...........Copa Catalunya, Voiturette Race of the Royal Automobile Club of Spain, near Barcelona.
June 2-8..........Prince Henry (German) Touring Competition.
June 13-18........Scotland, Scottish Reliability Trials.
June 20...........French Voiturette Race.
June 21...........French Stock-Car Race.
June 22-July 5....Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.
June 27...........Speed Trials at Kiev, Russia.
July 12-18........Ostend, Belgium, Automobile Week.
July 20-25........Boulogne, France, Automobile Week.
Aug. 1-15.........Ardennes, France, Meeting.
Aug. 15-Sept. 15..French Industrial Vehicle Trials.
Aug. 21...........Salon, France, One and Five Kilometer Trials.
Aug. 28...........Mont Ventoux, France, Hill-Climb.

Road Touring Test for Commercial Cars

Efficiency of trucks and traveling capacity of commercial vehicles are likely to be given a real test in the near future, if plans which are now being formed to hold a touring contest for such vehicles develop the way they are expected to.

Over a score of Western manufacturers have expressed themselves as desirous to enter such a contest and W. Irving Fickling, of New York City, has undertaken to conduct the preliminary work. So far, two American makes of commercial automobiles have been pledged to enter the contest if the proper organization takes hold of it and two foreign makers have also agreed to enter. These cars are the Rapid, Reliance, Panhard and Saurer. In addition it is hoped that a dozen other varieties will be attracted, contingent of course upon satisfactory rules, dates and routes.

According to tentative plans already submitted, the contest may extend over a week or a month. Charles E. Stone has formulated the following ideas upon which to base the tour: Each entrant may nominate one or more cars and shall have the privilege to name a technical expert to serve upon the committee who is not in any way affiliated with any competing company.

Vehicles should be required to carry the maximum catalogue load in sand bags supplied by those in charge of tests. The weight of the body should also be considered in the final reckoning. All vehicles should be fitted with some form of recording instrument showing speed, trip and total mileage.
